and Martin of the "triple compound" of iron, carbon, and manganese (spiegeleisen). The chief difficulty with all these attempts to manufacture steel by fusion in the reverberatory was the lack of efficient and economical means for the maintenance of the intense temperature required. This was supplied by the important invention of Siemens, the regenerative gas furnace (see FURNACE), in which the use of gas as fuel was perfectly realized. The effect of this invention was great and immediate in every branch of metallurgy involving very high temperatures, and nowhere more signal than in the remelting and subsequently in the direct manufacture of steel by fusion. Sudre, Alexandre, Attwood, and Brigues, Rambourg and co. (the last at Montluçon, under the advice of C. W. Siemens himself) attempted with the aid of the new system of heating to fuse cast iron with wrought iron or oxides of iron for the production of steel, and procured patents on the strength of their experiments. But the first practical success was that of Pierre and Émile Martin, whose method is set forth in their patents of 1865 and 1867. These metallurgists, after a series of experiments extending over many years, arrived at a combination of features, most of them separately known before, but constituting as a whole a new process, by which they were enabled to manufacture open-hearth steel of all grades, from the homogeneous metal approaching wrought iron to the hardest varieties, on a commercial scale and with profit. Naturally their claims as inventors, among so many eager competitors, were for a time contested; but the report in their favor of MM. Jordan and Burat, made in November, 1874, after an investigation extending over many months, for the tribunal of the Seine, will probably be accepted as conclusive. The Martin process is now widely employed in England, on the continent of Europe, and in the United States, and constitutes the only rival of the Bessemer method for the production of cheap steel. It consists essentially in the decarburization of cast iron by fusion with wrought iron, iron sponge, steel scrap, or iron oxide, in the hearth of a reverberatory furnace, heated with gas, the flame of which assists the reaction, and the subsequent recarburization or deoxidation of the bath by the addition at the close of the process of white iron, spiegeleisen, or ferromanganese. The period of fusion and decarburization lasts from four to eight hours; the amount of spiegeleisen or ferro-manganese added depends upon the condition of the bath, the grade of steel desired, and the percentage of manganese in the alloy used. The first of these elements is determined by samples taken from time to time during the process and tested. The advantages claimed for the Martin as compared with the Bessemer process are: its less expensive plant; the greater duration of the operation permitting by means of sampling more complete control of the quality of the product, and also conducing to greater uniformity of result; and, as a consequence of the foregoing, the practicability of employing materials which have not hitherto been considered suitable for the Bessemer converter. The greater variety of materials available for the Martin process also renders the direct conveyance of the molten pig from the blast furnace to the steel furnace an easier matter in this process than in the other, since the initial quality of the pig is of less importance. Yet this direct conveyance of the cast iron has thus far been practised in certain Bessemer works alone. The Martin process has been employed at Terre Noire in France, and by Mr. Slade at Trenton, N. J., for the production of phosphoric steel mentioned above. The production of Martin steel in this country has risen from 3,000 net tons in 1872 to 7,000 tons in 1874. The number of establishments using the process in 1874 was 13, and its introduction was in progress in other works. 3*b*. *Indian Steel, or Wootz.* This is produced by fusion of wrought iron with coal or carbonaceous substances in crucibles. Small pieces of iron made in the small native furnaces are put into a clay crucible with some dried wood and leaves, and covered securely with tempered clay. The crucibles are then heated until fusion is complete, when they are broken open, and a conical mass of steel weighing 2 or 2½ lbs. is obtained. This steel is generally very highly carburized, and requires to be worked at a low heat. It is much esteemed for its purity, but the production is small in amount. About the beginning of this century David Mushet carried out an extensive series of experiments on the fusion of wrought iron and charcoal in crucibles, and determined the amount of charcoal necessary for the production of steel of different degrees of hardness. Since then numberless patents have been secured for mixtures for fusing in crucibles, comprising mainly the different varieties of pig iron, wrought iron, carbon, and oxide or other compound of manganese. The crucible steel of the present day is largely made from such mixtures, the quality of the product depending on the materials used. 3*c*. *Cement Steel.* The production of steel by heating wrought iron in charcoal without fusion (cementation) is a very old process, but its origin is unknown. It was described by Réaumur in 1722, and has not been materially changed since. Notwithstanding the introduction of modern processes, this method is still employed for the manufacture of the higher grades of steel for tools and other fine purposes. The iron is in the form of flat bars about ¾ in. thick. These are arranged in layers in long boxes or chests of fire brick, each layer being covered with charcoal about ½ in. thick. When the box is full, it is covered with clay or other impervious material, and heated to bright redness for seven to ten days, according to the degree of carburization re-

quired. Trial bars are inserted with their ends protruding, which may be withdrawn from time to time and the progress of the conversion judged from the appearance of the fracture. When the desired end has been attained, the fires are withdrawn and the boxes allowed to cool slowly for several days. The bars after conversion generally have blisters on the surface, apparently formed by the pressure of some gas from within the bar; hence the name "blister steel." The bars, originally soft and tough, are found after conversion to be hard and brittle, and the freshly fractured surface shows a steely appearance. Analyses of successive layers of the bar after conversion show that the carburization proceeds gradually from the surface to the interior, the iron near the surface being much more highly carburized than that at the centre. In order to obtain uniformity in cement steel, it is therefore necessary either to weld several bars together by repeated rolling or hammering, or by melting the bars in crucibles. The former process is adopted only for the softer cement steels, and furnishes shear steel. The use of this welded steel has been generally superseded by cast steel, but it is still employed for many purposes, particularly for welding to iron. The melting of steel is usually effected in covered crucibles capable of holding 40 to 80 lbs. of metal. They are made of refractory clay or of graphite with sufficient clay to give it coherence. These crucibles are placed in furnaces arranged in a straight line, with their tops or openings on a level with the working floor of the casting house. Each furnace is a rectangular chamber of fire brick, capable of holding two crucibles, and has a separate flue. Siemens's regenerative furnace is also largely used for heating crucibles for steel melting. When the steel is thoroughly melted the crucible is drawn out of the furnace, and the molten metal cast in the form of rectangular ingots or into special moulds. Where large castings are to be made of crucible steel, the metal from several crucibles is first poured into a common receptacle, and thence into the moulds. Case-hardening of wrought iron consists in a superficial conversion of the iron into steel by heating it with animal charcoal or organic matters in the same manner as that employed for cement steel, but for a shorter time. Or the iron to be hardened may be simply heated to redness and covered with a carbonaceous substance like prussiate of potash or cyanide of potassium, which will cause a superficial carburization. Case-hardening is employed for objects which should have a hard and steely surface combined with the toughness of wrought iron. 3*d*. *Mackintosh or Baron Steel*. The carburization of wrought iron by means of gaseous hydrocarbons without fusion was proposed in 1824, and was patented in England in 1825 by Charles Mackintosh. It has recently been revived under the name of the Baron process, but has not been made practically successful. The conversion is effected at a white heat, and is said to be complete in a few hours.—The limits of this article would not admit of even the enumeration of all the steel-making processes which modern inventors have suggested or endeavored to carry out. A large number of these inventions deal with the direct production of steel from the ore by processes similar to those described under IRON MANUFACTURE, and a still larger number with the direct conversion of pig iron into steel.—PROPERTIES AND TREATMENT OF STEEL. The physical properties of steel vary according to its composition, structure, and treatment. Thus the specific gravity of blister steel was found by Kirkaldy to vary from 7·7080 to 7·7327; of puddled steel, from 7·6237 to 7·7345; and of cast steel, from 7·8110 to 7·8303. The effect of the amount of carbon, and also of hardening, on the specific gravity, is shown in the following series of Swedish Bessemer steels:

| PER CENT. OF CARBON. | Sp. gr., soft. | Sp. gr., hardened. |
|---|---|---|
| 1·5 | 7·785 | 7·736 |
| 1·2 | 7·832 | 7·771 |
| 0·9 | 7·874 | 7·803 |
| 0·6 | 7·879 | 7·807 |
| 0·4 | 7·893 | 7·839 |

The appearance of the freshly fractured surface of cast steel depends likewise on the amount of carbon and on the degree of hardening. The more carbon present, the closer and more highly crystalline is the grain of the steel, and the lighter the color; effects which are all enhanced by hardening. Steel, unlike soft iron, has the property of retaining magnetism, its capacity in this regard increasing with the amount of carbon.—*Hardening, Tempering, and Annealing*. Steel is hardened by suddenly cooling it from a red heat through immersion in water, oil, or other liquid. The degree of hardness thus produced is proportional to the amount of carbon in the steel and the rapidity of its cooling. Hardened steel heated to redness and allowed to cool slowly recovers its original softness and malleability (annealing); but when hardened steel is heated to a temperature considerably below redness, and cooled, it is only softened to a degree inversely proportional, generally, to the temperature of the previous heating. This process is called tempering. For temperatures considerably below red heat, it is practically indifferent whether the cooling be slow or rapid. The operations of hardening and tempering are dependent on many conditions, such as the composition of the steel, the temperature to which it is heated, the temperature, specific heat, boiling point, mobility of particles, and heat-conducting power of the liquid in which it is cooled, &c. The following table shows the temperatures employed in tempering for different purposes, and the color indicative of each temperature, which appears on the surface of polished steel as it reaches the given degree. From these

colors, probably due to superficial oxidation, the experienced workman judges of the temper which the steel will assume:

| TEMPERATURE. | | Color. | Corresponding temper, suitable for |
|---|---|---|---|
| Fahr. | Centigrade. | | |
| 430° | 221° | Very pale yellow. | Lancets. |
| 450 | 232 | Pale straw. | Razors and surgical instruments. |
| 470 | 243 | Full yellow. | Penknives. |
| 490 | 254 | Brown. | Scissors, cold chisels. |
| 510 | 265 | Brown with purple spots. | Axes, plane irons. |
| 530 | 277 | Purple. | Table knives. |
| 550 | 288 | Bright blue. | Sw'ds, watch springs. |
| 560 | 293 | Full blue. | Fine saws, augers. |
| 600 | 316 | Dark blue. | Hand and pit saws. |

Polished articles may be heated for tempering over or between iron plates, in a gas flame, in molten lead, or in various other ways, until the proper color appears. For articles not polished, the temperature must be otherwise determined, as by heating in oil or tallow or in alloys of known fusibility. When oil or melted tallow begins to smoke, its temperature corresponds with that indicated by straw color on the polished steel; darker and more abundant smoke corresponds with brown; black and still more abundant smoke rises at 530°, the temperature of purple; when the vapor takes fire from a lighted taper, without continuing to burn, the temperature is about 580°; and finally, when the oil burns and rises in the vessel, the point of dark blue has been reached. The following table shows the fusing point of several alloys of tin and lead:

| Lead, parts. | Tin, parts. | Fusing point, deg. F. | Lead, parts. | Tin, parts. | Fusing point, deg. F. |
|---|---|---|---|---|---|
| 7 | 4 | 420 | 19 | 4 | 509 |
| 7½ | 4 | 430 | 30 | 4 | 530 |
| 8 | 4 | 442 | 48 | 4 | 550 |
| 8½ | 4 | 450 | 50 | 2 | 558 |
| 10 | 4 | 470 | Boil'g linseed oil | | 600 |
| 14 | 4 | 490 | Melting lead.... | | 612 |

Steels containing other substances besides carbon appear to require different treatment from pure carbon steels. Thus tungsten and titanium steels, so called, if heated bright red and suddenly cooled, are said to become excessively brittle; they must therefore be manipulated at low temperature. Too little is known of these compound steels to permit inferences as to their physical behavior. The hardening of large or irregular masses of steel requires great care. Unequal cooling causes fracture. Generally the more massive portions are first dipped in the liquid, and the thinner portions last; or, in case of any great disparity, special means are adopted to retard the cooling of the smaller parts. The causes of the phenomena attendant upon hardening and tempering steel were long involved in mystery, and are not yet all known with certainty. What is clearly known on the subject may be briefly stated. The degree of hardness assumed on cooling by a given steel is dependent on the rate of cooling. Caron says the degree of hardening is inversely proportional to the square of the time. The liquids which favor rapid cooling are those having a high specific heat and a low boiling point. Water fulfils these conditions in an eminent degree, while oil has a much lower specific heat and a much higher boiling point; consequently cooling in oil is a more gradual process than in an equal volume of water. Increasing the volume of the liquid and maintaining agitation, so as to diffuse rapidly the heat received from the steel, of course hastens cooling. The most rapid cooling is produced by mercury, by reason of its high conducting power. It is sometimes used to produce extreme hardness. But obviously the initial temperature of the cooling liquid is an essential point; so that heated mercury or fusible alloys could be used to effect slow cooling. Ordinary tempering is a partial annealing; that is, excessive hardness having been imparted to the steel, the excess is removed to the degree desired. It has been found in most cases practically easier to attain an accurate result in this way than by a single process of hardening, arrested at the desired point. But recent experiments by Caron have shown that it is possible, in some cases at least, to effect the hardening in one operation by carefully adjusting the amount and temperature of the water. Water at 131° F. was found to give results with some objects equal to those produced by the most careful hardening and tempering. Caron has further found that hardening of steel with 0·2 to 0·4 per cent. of carbon in warm, or still better in boiling water, was accompanied by an increase of its tenacity and elasticity without a material impairment of its hardness.—The toughening of large steel objects, such as cannon, is effected by heating them to redness and immersing in oil, where they gradually cool. This process has been recommended for steel rails. The hardening of steel is probably due both to a chemical combination of the carbon (present partly as graphite in soft steel) with the iron, and to a state of tension among the particles, conditions which are both removed by annealing. The tension in a bar of hardened steel is shown by cutting it in two lengthwise, when each piece assumes a curved form, concave on the cut side. Soft iron does not harden when suddenly cooled, but acquires increased rigidity and tensile strength; while cast iron, containing more carbon than steel, becomes under the same treatment extremely hard (chilled iron), often harder than steel. The freshly fractured surface of hardened steel shows a fine grain, often velvety in appearance; that of soft steel presents facets. In the former, analysis shows no uncombined carbon; in the latter, a small amount of graphite is almost always present. Steel expands on hardening, and loses specific gravity. Elsner found one sample to change in gravity from 7·9288 to

7·6578, and another from 8·0923 to 7·6578. Caron found a decrease from 7·817 to 7·743. The latter found that hammered steel on hardening lost in length and gained in other dimensions, while rolled steel gained in length. The effect of hardening on the tenacity of steel is discussed under Iron, and also further on in this article. Steel over-heated becomes brittle, and is said to be burnt. Whether this impaired cohesion is due to oxide of iron, or, as has been suggested, to carbonic oxide (either of which might be formed at high temperatures with access of air), or to a crystallization of the particles, is not certainly known. Many fluxes have been suggested for restoring burnt steel. They usually contain easily fusible substances, such as alkalies, borax, &c., combined with carbonaceous compounds, such as prussiate of potash. Hammering at a high heat is said to restore burnt steel.—The working of steel requires great skill and judgment. It cannot be wrought at very high temperatures; and the more carbon it contains, the lower must be the heat of working. The harder steels are generally hammered at a cherry-red heat. On the other hand, working at too low a temperature seriously impairs the tenacity of steel, as is abundantly shown by experience with steel rails. Welding steel to steel or steel to iron is difficult, except with the softest or least carburized varieties. Fluxes to facilitate such welding are largely used with good effect; they add nothing to the intimacy of the weld, their action being mechanical only (cleansing, exclusion of air, &c.), as in the case of iron welding. There is always danger of the separation of iron and steel at the weld, unless the latter is very soft. Special devices, such as causing one of the metals so welded to overlap and enclose the other, counteract this tendency in part. Or fluid steel may be cast directly around white-hot wrought iron, the weld being promoted by subsequent rolling or hammering. Sometimes the iron and steel to be welded are enclosed in a case of thin wrought iron and exposed to a welding heat, the enclosure preventing an access of air and oxidation of the surfaces of the metal.—*Strength of Steel.* The cohesive force of steel is usually considered under the different heads of absolute strength, or the force required to produce rupture; the elastic limit, or the least force by which a permanent alteration of form is effected; and the extensibility, or the amount of elongation under a breaking stress. The experimental data are referred, for convenience of comparison, to bars or rods of one square inch section. The above named properties are dependent, first, on the chemical composition of the metal; secondly, on its homogeneity; thirdly, on its molecular structure; and fourthly, on the temperature. (For comparison of the strength of cast iron, wrought iron, and steel, see Iron.) 1. The effect of the amount of carbon on the properties of steel is shown in the following tables compiled from Knut Styffe's work on the "Elasticity, Extensibility, and Tensile Strength of Iron and Steel:"

| PUDDLED STEEL—SQUARE BARS. | Breaking weight per sq. in. of original mean area, in lbs. | Breaking weight referred to area of fracture. |
|---|---|---|
| Hard steel, with 0·6 to 0·8 per cent. carbon | 89,189 | 122,240 |
| Middling hard, with 0·55 to 0·7 per cent. carbon | 80,628 | 115,670 |
| Soft steel, with less than 0·5 per cent. carbon | 70,272 | 112,593 |
| Puddled iron, with 0·2 per cent. carbon | 48,319 | 120,770 |

BESSEMER STEEL.

| CARBON, PER CENT. | Elastic limit. | Breaking weight per sq. in. of original area, in lbs. | Breaking weight, fractured area. | Elongation by rupture per cent. |
|---|---|---|---|---|
| 2·16 | 64,502 | 86,804 | 89,617 | 2·96 |
| 1·85 | 57,640 | 99,842 | 102,178 | 1·75 |
| 1·35 | 76,511 | 107,184 | 137,308 | 2·80 |
| 1·14 | 85,431 | 127,564 | 216,158 | 2·90 |
| 1·05 | 68,620 | 108,213 | 176,422 | 2·90 |
| 0·99 | 65,875 | 102,998 | 106,223 | 3·70 |
| 0·68 | 68,620 | 101,214 | 155,218 | 3·70 |
| 0·42 | ...... | 68,757 | 161,325 | 16·70 |
| 0·38 | 34,990 | 64,708 | 141,219 | 16·70 |
| .... | 41,251 | 68,268 | ...... | 24·50 |

The last sample was homogeneous iron prepared with ferro-manganese. To interpret correctly results like the above, it is necessary to eliminate all disturbing influences of composition and treatment. While these figures do not show a uniform change of properties with gradually increasing amounts of carbon, they nevertheless show decidedly that the effect of carbon on iron is to increase its absolute strength and elastic limit, and to decrease its extensibility. An increase of carbon beyond 1·2 per cent. is not accompanied, as a rule, by an increase in absolute strength. When reference is had to the fractured area, it will be seen that the force required to produce rupture does not differ as widely in different steels as when the original area alone is considered. The effect of melting, or in other words of the homogeneity of steel, is strikingly shown by a comparison of the two preceding tables, the former referring to puddled or welded steel, and the latter to Bessemer or homogeneous steel. The effect of molecular structure on the physical properties of steel has been partially treated under Iron. The table, vol. ix., p. 374, shows that the effect of hardening is to increase greatly the strength and elastic limit in steel, and to decrease its extensibility. The data given by J. Barba ("Memoir on the Uses of Steel") show that as the proportion of carbon decreases, the effect of sudden cooling becomes less marked, but even the softest iron is made somewhat more rigid by this treatment. The effect of hardening and tempering is, further, well shown by the following results of experiments on bars of steel cut from the same mass and submitted to a different treatment, made with reference

to the use of steel for the construction of the bridge over the Mississippi at St. Louis:

| CONDITION OF STEEL. | Tensile strength, lbs. per square inch. | Crushing strength, lbs. per square inch. |
|---|---|---|
| No. 1. In its original condition.......... | 109,473 to 131,864 | 100,080 to 112,400 |
| No. 2. Heated to bright red and cooled in oil at 78°..... | 201,341 to 227,542 | 173,200 to 199,200 |
| No. 3. Heated to bright red, hardened in water at 72°, and tempered at blue heat......... | 152,533 to 176,084 | 325,400 to 400,000 |
| No. 4. Heated to bright red and hardened in water at 72°............ | 132,659 to 150,480 | 275,640 to 381,680 |

—The change of molecular structure resulting from working steel when cold has lately demanded attentive consideration from engineers, owing to the increased use of steel for construction and for the permanent ways of railroads. All violent mechanical treatment of steel after it has become cold, such as rolling, hammering, punching, notching, &c., is found to impair its strength seriously. Sandberg has stated that the strength of steel rails notched on the flange was decreased from 50 to 97 per cent.; the former where the notch was semicircular, the latter where the notch was square. It is evident that this decrease of strength is not alone due to the removal of so much material, but that there must be a local tension of the particles which leads to rupture, and annealing is found to remove this tension. —The variety of opinions entertained by engineers as to the principal causes of fracture of steel rails is shown in the following summary of answers recently obtained from the administrations of 24 German railways in response to the request of a commission appointed to investigate this subject. The figures in parentheses indicate the number of administrations mentioning the prefixed cause. 1. The employment of too brittle metal (8). 2. Manufacture at too high temperature (2). 3. Rolling at too low temperature (3). 4. Cooling irregularly or too rapidly after rolling (5). 5. straightening cold, producing fissures which enlarge and result in fracture (15); producing a change of structure (1). 6. Notching the flange (14) (only two denied this cause). 7. Manner of piercing the holes (6). 8. Reduction of area of section of rails by the holes (1). 9. Bending the rails for laying on curves (3). 10. Rough handling of rails, such as throwing from cars to the ground, giving rise to fissures which result in fracture (9). It will be noticed that the majority of answers agree in attributing the fracture of rails to improper treatment of the steel when cold. The cause of the brittleness and impaired strength in steel and iron consequent upon punching has been investigated in Lorient, France, by J. Barba, who has found that cold punching induces a local hardening and tension of the metal, in a zone less than 0·04 in. wide, around the hole, and that when this hardened portion is filed or cut away, or softened and relaxed by annealing, the metal regains its original strength and extensibility. He thinks the hardening due to the combination of carbon and iron, as is also supposed to be the case when steel is hardened by heating and sudden cooling. Indeed, this heating and cooling is what undoubtedly occurs to the immediately adjacent metal in punching. The diminished strength of punched plates is caused by this narrow hardened portion, which, owing to its decreased extensibility, receives the full effect of the stress, a rupture being produced in this portion and then extending throughout the whole mass of metal. The same effect, in an enhanced degree, would follow blows or shocks. The following are among the results obtained by Barba:

TERRE NOIRE BESSEMER STEEL.

| SIZE AND CHARACTER OF HOLE. | TENSILE STRENGTH IN TONS PER SQ. IN. | |
|---|---|---|
| | Bar 1·96 in. wide. | Bar 1·771 in. wide. |
| Cylindrical hole punched, 0·669 in....... | 25·86 | 27·76 |
| Hole enlarged to 0·774 in................ | 32·20 | ..... |
| Cylindrical hole drilled, 0·669 in........ | ...... | 34·61 |
| Cylindrical hole punched, 0·590 in., enlarged to 0·669 in..................... | ...... | 33·98 |

The effect of annealing after punching is shown in the following:

| CHARACTER OF BAR. | Tensile strength in tons per sq. in. |
|---|---|
| Punched bar.............................. | 24·47 |
| " " annealed...................... | 29·48 |
| Drilled bar.............................. | 29·98 |
| Punched, enlarged, and annealed............ | 30·30 |

The effect of temperature on the strength of steel has already been considered under IRON. More recently Joule has experimented on the tensile strength of steel bars, and confirms the result of previous investigations, that the tensile strength is not impaired by reduction of temperature. In determining the effect of blows at reduced temperatures, he experimented on cast-iron nails, and found that as many nails broke at ordinary as at freezing temperatures when exposed to a falling weight. These results must not be regarded as contradicting those of Sandberg on iron rails, nor does it follow that the same effect would have been produced had steel bars been used instead of cast iron.—*Uses of Steel.* The industrial applications of steel, formerly confined mainly to tools, weapons, and springs, have been widely extended since the introduction of the Bessemer and Martin processes. Among the principal modern uses of steel are rails, boilers, machinery, bridge construction, and ship building. The fact must not be overlooked that the term steel is now generally applied to all homogeneous, malleable compounds of iron, and includes products of all degrees of hard-

ness and rigidity. The adoption of steel for any particular purpose must, therefore, be intelligently based on its composition, structure, and treatment.—*Production of Steel in the United States.* The following statistics are compiled from the report of the secretary of the American iron and steel association, of January, 1875:

PRODUCTION BY YEARS IN NET TONS.

| YEARS. | Bessemer steel. | Other steel. |
|---|---|---|
| 1865 | ...... | 15,262 |
| 1866 | ...... | 18,973 |
| 1867 | 3,000 | 19,000 |
| 1868 | 8,500 | 21,500 |
| 1869 | 12,000 | 23,000 |
| 1870 | 40,000 | 35,000 |
| 1871 | 45,000 | 37,000 |
| 1872 | 110,500 | 38,000 |
| 1873 | 157,000 | 50,000 |
| 1874 | 176,579 | 47,481 |

Of the Bessemer production there was made into rails: in 1872, 94,070 tons; 1873, 129,015; 1874, 144,944. The importations of Bessemer rails for three years were 149,786, 159,571, and 100,486 tons, valued at $8,207,013, $8,984,103, and $6,838,875, gold, respectively. The average price in currency at which American steel rails have been sold at the works since the establishment of the industry is as follows: 1867, $160; 1868, $158½; 1869, $132¼; 1870, $106¾; 1871, $102½; 1872, $112; 1873, $120½; 1874, $94¼; 1875, $75. Of the steel other than Bessemer produced in 1874, 34,128 tons was crucible steel, the remainder puddled, open hearth, and blister steel.

**STEEL, Dephosphorization of.** See p. 897.

**STEELE**, a S. E. county of Minnesota, drained by the Lester river and branches of Cannon river; area, 432 sq. m.; pop. in 1870, 8,271. The surface is undulating, and the soil fertile. There are three or four small lakes and several fine streams. The chief productions in 1870 were 385,214 bushels of wheat, 82,040 of Indian corn, 230,421 of oats, 12,709 of barley, 36,025 of potatoes, 19,928 tons of hay, 7,172 lbs. of wool, 208,249 of butter, and 8,700 of hops. There were 1,971 horses, 2,846 milch cows, 3,794 other cattle, 2,785 sheep, and 2,006 swine. The Chicago, Milwaukee, and St. Paul, and the Chicago and Northwestern railroads pass through the capital, Owatonna.

**STEELE, Sir Richard**, a British author, born in Dublin in 1671, died at Llangunnor, near Carmarthen, Wales, Sept. 1, 1729. He received his early education at the Charterhouse, where his intimacy with Addison was formed. In 1691 he entered Merton college, Oxford, but left at the expiration of three years without taking a degree, enlisted as a private in the horse guards, and reached the rank of captain in Lucas's fusileers, an appointment due to his colonel, Lord Cutts, to whom he had dedicated "The Christian Hero" (1701). In odd contrast with this work was his comedy of "The Funeral, or Grief à la Mode" (1702), which was followed by "The Tender Husband" (1703), and "The Lying Lover" (1704). He was appointed "gazetteer" and gentleman usher to Prince George of Denmark, and derived ample means from two wealthy marriages (the last in 1707), but was always in pecuniary trouble through reckless expenditure and dissipation, his life being passed, as he says, in "sinning and repenting." In 1709 he commenced the "Tatler," for which Addison furnished many of the leading papers, though by no means so many as Steele, whom he now assisted to the appointment of a commissioner of the stamp office. With the overthrow of the whigs in 1710 he lost his office of gazetteer, and with it the means of supplying the items of official news which at first formed an important feature in the "Tatler." This paper was accordingly succeeded in 1711 by the "Spectator," written chiefly by Steele and Addison, and subsequently by the "Guardian," begun and ended in 1713, and the "Lover," the "Reader," and other periodicals which had but a brief existence. In 1713 Steele resigned his office, and was returned to parliament from Stockbridge in Hampshire; but for writing articles in the "Crisis" and the "Englishman," adjudged to have been libels against her majesty's administration, he was expelled by a vote of 245 to 152. His pen, however, continued to be actively employed in the whig interest, and on the accession of George I. he received several profitable appointments, was knighted, and elected to parliament from Boroughbridge. In 1722 he produced his last and best comedy, "The Conscious Lovers," which proved completely successful, and brought him in ample receipts; but he was soon reduced to straits again. A paralytic attack rendered him incapable of further literary labor, and he retired to a small estate near Carmarthen left him by his second wife, where he died almost forgotten by his contemporaries. He first conceived the characters of Sir Roger de Coverley, Will Honeycomb, and others of the Spectator club, which received their finishing touches from the hand of Addison. His letters to his wife, about 400 in number, form one of the most singular correspondences ever published.—There is an elaborate treatise on the character and genius of Steele in Forster's "Historical and Biographical Essays;" and Thackeray, in his "Lectures on the English Humorists," has treated the same subject at length. See also "Memoirs of the Life and Writings of Sir Richard Steele," with his correspondence, by H. R. Montgomery (2 vols. 8vo, London, 1865).

**STEEL ENGRAVING.** See ENGRAVING.

**STEELL, Sir John.** See p. 898.

**STEELYARD.** See BALANCE.

**STEEN, Jan**, a Dutch painter, born in Leyden in 1636, died in Delft in 1689. He studied under Brouwer and Van Goyen, whose daughter he married. According to Kugler, he brought into full play all the elements of genuine low comedy. In the museum at the Hague

is his well known "Representation of Human Life." He painted in all about 300 pictures. —See *J. Steen, Étude sur l'art en Hollande*, by Van Westrheenen (the Hague, 1856).

**STEERING APPARATUS,** the appliances by which vessels are guided through the water. The earliest method was by a long oar passed out of the stern. An oar is a very efficient means of steering boats, and is still employed on whale boats, rafts, &c. The rudder governs a ship's motion by being turned so that its plane is in a position oblique to the plane of the masts and keel, and the reaction of the water against it causes the ship to turn. The head of the rudder, projecting above the deck, is furnished with a horizontal handle or lever called the tiller, by which the rudder is turned. The term helm is often applied to this, as also to the rudder and tiller together. To keep the rudder in the desired position against the force of the waves, on small vessels a rope is made fast on the weather side by one end, while the other is held with a turn around the tiller. A block and tackle are required for larger vessels, replaced upon still larger ones by "the wheel." This is a wheel and axle set upon the tiller, the rope of which, making several turns round the axle, is carried toward each side of the ship, so that the turning of the axle draws the tiller toward that side the rope of which is being wound up. The handles for working the wheel appear as spokes extending beyond the periphery. On river steamers, to enable the steersman (in this case called a pilot) to guide the vessel from his own observation, the wheel is placed within a structure called the pilot house on the upper deck at the forward end, and connected with the rudder. For this purpose ropes were formerly used, but serious disasters having occurred from their being burned in case of fire, it is now a law in the United States that chains or iron rods shall be used. By the use of two screw propellers, one each side the rudder, it was found by Mr. Edwin A. Stevens of Hoboken, N. J., that when these are worked in opposite directions the vessel may be turned on its centre as a pivot; he adopted this plan for the "Stevens battery."

**STEEVENS, George,** an English editor, born at Stepney, May 10, 1736, died at Hampstead, Jan. 22, 1800. He was educated at Eton and Cambridge. His first publication, a reprint of "Twenty of the Plays of Shakespeare, being the whole Number printed in Quarto during his Lifetime" (4 vols. 8vo, 1766), contained in foot notes a variety of readings from other quarto editions. The reputation which he thereby acquired led to his association with Johnson in the preparation of the edition of Shakespeare published in 1773 with their joint names. Their second edition appeared in 1778, and in 1780 Malone, who had assisted Johnson and Steevens, published a supplement containing the doubtful plays and the poems. Steevens, associated with Isaac Reed, in the next twelve years prepared two new editions (10 vols. 8vo, 1785, and 15 vols., 1793), in which, "instead of a timid and servile adherence to ancient copies," he undertook the "expulsion of useless and supernumerary syllables, and an occasional supply of such as might fortuitously have been omitted." The text of these editions remained the standard for nearly 50 years.

**STEFFENS, Heinrich,** a German author, born in Stavanger, Norway, May 2, 1773, died in Berlin, Feb. 13, 1845. He studied theology and the natural sciences at Copenhagen, and afterward at Jena became a disciple of Schelling. After returning to Copenhagen he engaged, under the auspices of Werner at Freiberg, in geological labors. He was professor at Halle from 1804 to 1807, and again from 1809 to 1811, and subsequently at Breslau (except during his service in the army in 1814-'15) till 1831, when he was transferred to Berlin. He was associated with the principal philosophers and poets of his day, and also with Schleiermacher, and became known in theology first as a dissenter from and finally as an adherent of the strict doctrines of the old Lutherans. He excelled as a poetical and miscellaneous writer, but his reputation rests on his philosophical labors, in which, according to Michelet, "he most manifestly set forth the totality of the school of Schelling." His works include *Recension von Schelling's naturphilosophischen Schriften* (Jena, 1800); *Grundzüge der philosophischen Naturwissenschaft* (Berlin, 1806); *Handbuch der Oryktognosie* (3 vols., Halle, 1811 -'19); *Caricaturen des Heiligsten* (2 vols., Leipsic, 1819-'21); *Anthropologie* (2 vols., Breslau, 1822); *Von der falschen Theologie und dem wahren Glauben* (1824; new ed., 1831); *Wie ich wieder Lutheraner wurde und was mir das Lutherthum ist* (1831); *Novellen* (16 vols., 1837-'8); and *Was ich erlebte* (10 vols., 1840-'45; 2d ed., 1844-'6; abridged English translation by W. L. Gage, "The Story of my Career as Student at Freiberg and Jena," Boston, 1863; republished under the title "German University Life," Philadelphia, 1874).

**STEIN, Karl,** baron. See ALTENSTEIN.

**STEIN, Heinrich Friedrich Karl,** baron, a German statesman, born at Nassau, Oct. 26, 1757, died at Frücht, near Nassau, June 29, 1831. He studied at Göttingen, and rose to distinction in the department of mines in Westphalia. In 1804 he was chief of an economico-commercial department in the Prussian ministry of the interior, and abolished restrictions on trade and introduced other reforms. Foreseeing the calamities of Prussia, he urged in vain the union of all the German states. This made him uncongenial to Frederick William III., who removed him in January, 1807. But he was soon reinstated, and in July placed at the head of the ministry. He reorganized the whole civil service, abolished feudal usages, adopted a new scheme of militia, and opened the way for the Zollverein and the present unity of Germany. Napoleon, after favoring

Stein's accession, became in 1808 embittered against him on account of an intercepted letter in which the Prussian minister expressed a hope for his speedy downfall. Stein was obliged to leave the cabinet in November, and Napoleon outlawed him in December, and confiscated his property. He sought refuge in Austria, and in May, 1812, with the emperor Alexander in Russia. At the end of 1813, after the capture of Dresden by the allies, he was placed at the head of the council for the administration of the reconquered German territories, and exerted much influence on the memorable events of 1814–'15. In 1819 he formed a society for investigating early German history, and he promoted the publication of the celebrated *Monumenta Germaniæ Historica*. In 1827 he became a member of the Prussian council of state.—Pertz has edited *Denkschriften des Freiherrn vom Stein* (Berlin, 1828), and published *Das Leben des Ministers Freiherrn vom Stein* (6 vols., 1849–'55; abridged ed., *Aus Stein's Leben*, 2 vols., 1856). See also Stern, *Stein und sein Zeitalter* (Leipsic, 1855); Venedey, *Heinrich Friedrich Karl vom Stein* (Iserlohn, 1868); and Arndt, *Meine Wanderungen und Wandlungen mit dem Reichsfreiherrn vom Stein* (Berlin, 1858; 3d ed., 1870). Monuments were erected to him at Nassau in 1872, and in Berlin in 1875.

**STEIN, Charlotte Albertine Ernestine von**, a German baroness, born in Weimar, Dec. 25, 1742, died there, Jan. 6, 1827. She was a daughter of a marshal of the grand ducal court, and in 1764 married the baron Friedrich von Stein, to whom she bore seven children, and who died in 1793. She became intimate with Goethe soon after his first arrival at Weimar in 1775. In 1788, shortly after his return from Italy and the beginning of his liaison with his future wife Christiane Vulpius, Goethe broke off his relations with Frau von Stein, though she continued to exercise much influence upon his mind. Her tragedy *Dido*, edited by H. Düntzer (Leipsic, 1867), refers to Goethe and his Weimar contemporaries. A. Schott has edited Goethe's letters to her, excepting those from Italy (3 vols., Weimar, 1848–'51), and those addressed by him and his mother to Frau von Stein's son appeared in 1846. Her correspondence with Schiller's wife is contained in *Charlotte von Schiller und ihre Freunde* (2 vols., Stuttgart, 1865). See also *Charlotte von Stein*, by H. Düntzer (2 vols., 1874).

**STEIN, Lorenz**, a German political economist, born in Eckernförde, Schleswig, Nov. 15, 1815. He became professor at Kiel in 1846, was prominent in the movement for the independence of the duchies, represented the provisional government of Schleswig-Holstein at Paris in 1848, and was removed from his professorship in 1852. In 1855 he became professor of political sciences at Vienna. His works include *Französiche Staats- und Rechtsgeschichte* (3 vols., Basel, 1846–'8); *Geschichte der socialen Bewegung in Frankreich von 1789 bis auf unsere Tage* (new ed., 3 vols., Leipsic, 1849–'51); *System der Staatswissenschaften* (2 vols., Stuttgart, 1852–'6); *Lehrbuch der Finanzwissenschaft* (Leipsic, 1860; 2d ed., 1871); *Die Verwaltungslehre* (4 vols., Stuttgart, 1865–'8); *Die Lehre vom Heerwesen* (1874); and *Gegenwart und Zukunft der Rechts- und Staatswissenschaft Deutschlands* (1875).

**STEINBOCK.** See IBEX.

**STEINLE, Johann Eduard**, a German painter, born in Vienna in 1810. He studied in Munich, worked in Rome under Overbeck's direction, and painted in fresco "The Sermon on the Mount" in the chapel of Rheineck, the "Chorus of Angels" in the Cologne cathedral (1843), and the "Judgment of Solomon" in the Römer at Frankfort (1844). In 1850 he was appointed professor at the Städel institute. His subsequent works include "Christ as the Good Shepherd" and "The Lost Son."

**STEINTHAL, Heymann**, a German philologist, born of Jewish parents at Gröbzig, Anhalt, May 16, 1823. He studied in Berlin, and became a lecturer there on language and mythology. In 1852 he went to Paris to study Chinese, and in 1863 returned to Berlin as professor extraordinary. Besides editing with Lazarus the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* (Berlin, 1859 *et seq.*), he has published *Die Classification der Sprachen* (Berlin, 1850); *Der Ursprung der Sprache* (1851); *Die Entwickelung der Schrift* (1852); *Das gegenseitige Verhältniss der Grammatik, Logik und Psychologie* (1855); *Geschichte der Sprachwissenschaft bei den Griechen* (1863); *Die Mande-Negersprachen* (1867); and *Abriss der Sprachwissenschaft* (1871 *et seq.*).

**STELLIO** (Daud.), a genus of iguanian lizards, characterized by a triangular, flattened head, covered with numerous small spinous plates; body depressed, the scales having intermixed some larger and rougher plates; a longitudinal fold on each side between the legs; no femoral pores, and no dorsal or caudal crest; anal pores distinct; tail with large keeled and spiny scales arranged in whorls; incisors four above, canines two above and none below, and cheek teeth triangular; no teeth on palate; tongue thick and fleshy. The common stellio (*S. vulgaris*, Daud.), the *lacerta stellio* of Linnæus, the *hardun* of the Arabs, is about a foot long, of which the tail is not quite one half; the color is olive, shaded and spotted with black above and olive yellow below. It is common in the Levant, and especially in Egypt, where its excrements were formerly collected and used in making cosmetics; it is very active, feeding on insects, and living in ruins, clefts of rocks, and holes in the ground. The *stellio* of the ancients was a species of gecko, and probably the *ptyodactylus Hasselquistii* (Dum. and Bibr.). (See GECKO.)

**STENDHAL.** See BEYLE.

**STENO, Nicolas**, a Danish anatomist, born in Copenhagen in 1638, died in 1686. He studied medicine at Copenhagen and afterward at Ley-

den, where he graduated in 1664. Very early in his professional life he discovered the existence, course, and office of the excretory duct of the parotid gland, since known as "Steno's duct." He acquired reputation by his anatomical writings, became physician to the grand duke of Tuscany, and afterward professor of anatomy at Copenhagen. Returning to Florence, he became a Catholic in 1669 and a priest in 1677, and was for the rest of his life a missionary with the title of apostolic vicar of the see of Rome for all the north.

**STENOGRAPHY**, a method of abbreviating ordinary writing by the use of signs, now almost universally superseded by phonography or phonetic shorthand. (See PHONOGRAPHY.)

**STENTOR**, a Grecian herald in the Trojan war, from whose name is derived the word stentorian. Homer describes him as "great-hearted, brazen-voiced Stentor, who shouted as loud as fifty other men."

**STEPHEN** (Gr. *στέφανος*, a crown), **Saint**, the first martyr of the Christian church. He was a Hellenist by birth, and one of the seven deacons in the Christian congregation of Jerusalem, who, upon the complaint of the Hellenists that their widows were neglected, had been chosen by order of the apostles to superintend everything connected with the relief of the poor. The Jews charged him with speaking against the law and the temple, against Moses, and against God, and by order of the sanhedrim he was stoned. (Acts vi. and vii.) His death is believed to have happened in the year 36 or 37. His feast has been celebrated in the eastern and western churches on Dec. 26 since the 4th century.

**STEPHEN**, the name of ten popes, of whom the following are most important. **I. Stephen I., Saint**, born in Rome about 200, died there in 257 (according to some authorities in 260). He was elected in 253 (or 257). His pontificate is remarkable for his having deposed, at the instance of St. Cyprian, the Novatian Marcianus, bishop of Arles, for having reversed the sentence of a Spanish synod deposing two bishops accused of apostasy; and for a memorable controversy with St. Cyprian relating to the necessity of rebaptizing converted heretics. Only fragments of Stephen's epistles are extant. He was put to death during the persecution of Valerian. **II. Stephen III.** (called by French historians Stephen II.), born in Rome about 690, died there in April, 757. He was educated in the school of St. John Lateran, and was a canon regular of that basilica when he was chosen pope, in March, 752, as successor of Stephen II., who died three days after his election, without having received episcopal consecration. Stephen III., immediately after his accession, opposed Astolphus, king of the Lombards, who had possessed himself of Ravenna and its dependent provinces, and demanded the surrender of Rome and its territory. Having for a year vainly sought the armed intervention of the Greek emperor Constantine V., the pope went to Pavia in October, 753, to conciliate Astolphus, and thence to Pontyon in Champagne, in January, 754, where he implored the protection of Pepin, king of the Franks. During Eastertide an assembly was held at Quercy-sur-Oise, at which Pepin and his nobles pledged themselves to defend the pope, and the latter gave a series of decisions relating to matrimony and church government. In July he consecrated the abbey church of St. Denis near Paris, and anointed and crowned Pepin and his sons Carloman and Charles (afterward Charlemagne), and returned to Italy with Pepin and a powerful army. Astolphus was forced to give up the exarchate of Ravenna; but after the departure of Pepin in December he reoccupied these territories and besieged Stephen in Rome. Pepin recrossed the Alps early in 755, defeated Astolphus, and compelled him by treaty to make over the exarchate to the pope. This treaty, which was signed by Pepin, his sons, and the chief Frankish barons and prelates, assigned the reconquered provinces as a gift "to the blessed Peter, the holy church of God, and the Roman republic," and inaugurated the temporalities of the Roman see. In 756 Desiderius, the successor of Astolphus, ratified this treaty as a condition to his being recognized by Stephen and Pepin. The literary remains of Stephen III. consist of important letters contained in the *Codex Carolinus*, and of his *Responsa ad Gallos*, in Labbe's *Concilia*. **III. Stephen X.** (Frederick of Lorraine), born about 1000, died in Florence in 1058. He was brother to Godfrey of Lorraine, duke of Tuscany. Pope Leo IX. made him a cardinal, and in 1054 sent him as legate to Constantinople. On his return in 1055, his life being threatened by the emperor Henry III., he fled to Monte Casino, and became a Benedictine monk in that monastery, and in May, 1057, its abbot. He was made cardinal priest by Pope Victor II., in whose place he was elected in August, 1057, by the influence of Cardinal Hildebrand (afterward Pope Gregory VII.). He held several councils in Rome for the enforcement of sacerdotal celibacy, and degraded all incontinent clerics who had violated the statutes of Pope Leo IX. He visited Monte Casino, caused an abbot to be elected in his own place, compelled the monks to reform all abuses incompatible with their vow of poverty, and created Pietro Damiani cardinal. He issued the most rigorous decrees against simony, but maintained the exemption of clergymen from trial by lay judges, and from being taxed without the authorization of the holy see.

**STEPHEN**, king of England, the fourth and last of the Anglo-Norman line, born about 1100, died Oct. 25, 1154. His father was Stephen, count of Blois, and his mother was Adela or Adelicia, the fourth or fifth daughter of William the Conqueror; and Stephen was their third son and sixth child. He early be-

came a favorite of Henry I., his maternal uncle, who knighted him in his youth, and gave him the earldom of Mortagne in Normandy and several valuable estates in England. Henry procured his marriage to Matilda, heiress to the count of Boulogne, as early as 1114, by which Stephen became possessed of that title and property. When, in 1120, William, the heir of Henry I., and so many other members of the king's family and household, were lost by the foundering of the White ship, Stephen had been saved from the same fate by leaving the vessel on finding that she was too crowded for safety. Stephen with other nobles took the oath to support Henry's daughter the empress Matilda as queen of England and duchess of Normandy, should her father die without issue male; but her subsequent marriage with Geoffrey Plantagenet, count of Anjou, in violation of the king's assurance, was thought to have cancelled the obligation. Theobald, count of Blois, Stephen's eldest brother, was regarded by many Normans as the proper person to succeed Henry; but while they were deliberating, Stephen hastened to England, and was crowned in December, 1135. He confirmed to the English the immunities and laws of Henry I., and also the laws and customs of Edward the Confessor. He secured peace with Scotland by making cessions to King David, from whom he obtained acknowledgment and homage. At a meeting of barons and prelates at Oxford, he produced a letter from the pope approving his election to the throne. A charter was framed, by which the old privileges of all classes were confirmed, and certain abuses of the preceding reign were removed. The reign of Stephen was a period of constant war and tumult. He was involved in contests with the Welsh, who inflicted defeat and loss on the English. In the war that was renewed with Scotland in 1138, the English gained the great battle of the standard, Aug. 22. Revolts broke out, at different times, in various parts of the country. The cause of the empress Matilda was early taken up by a party in England, headed by her natural brother Robert, earl of Gloucester; and on Sept. 30, 1139, Matilda landed in England. Stephen was defeated and made prisoner, Feb. 2, 1141, at the battle of Lincoln. The greater portion of the country submitted to the victors; but Matilda's arrogance was so offensive that a reaction speedily took place. Her brother was defeated and captured in September, 1141, and was exchanged for Stephen. At the battle of Wilton, July 1, 1143, Gloucester was victorious, and the king preserved his freedom only by flight. The war raged for years, and the condition of England was made most deplorable. In 1153 Henry, son of Matilda, arrived in England at the head of a considerable force, and defeated Stephen at Malmesbury; but leading men on both sides now interposed to bring about a peace, which was facilitated by the sudden death of the king's eldest son, Eustace. By the treaty of Winchester, Nov. 7, 1153, it was settled that Stephen should remain king of England for life, and that he should be succeeded by Henry; and that Stephen's son William should retain all his possessions acquired by marriage or otherwise, and all those which his father had held in Normandy, England, and elsewhere, before he became king. Stephen did not survive the making of this treaty quite one year. His reign was the most miserable time ever known in England. The country was covered with castles, many hundreds of which were erected at this period; and it was devastated by the foreign soldiery, the king himself employing numerous mercenaries, principally from Flanders and Brittany. The throne passed on his death to the house of Plantagenet in the person of Henry II.

**STEPHEN I., Saint**, king of Hungary. See Hungary, vol. ix., p. 55.

**STEPHEN**, king of Poland. See Báthori, and Poland, vol. xiii., p. 646.

**STEPHEN. I. Sir James**, an English statesman, born in London, Jan. 3, 1789, died in Coblentz, Sept. 15, 1859. He graduated at Cambridge in 1812, and was called to the bar at Lincoln's Inn. He was appointed counsel in the colonial department of the public service, and in 1824 counsel to the board of trade. In 1834 he was made assistant and subsequently permanent under-secretary, and retired from office in 1847, when he was knighted. From 1849 till his death he was regius professor of modern history in the university of Cambridge. He published "Essays in Ecclesiastical Biography and other Subjects" (2 vols. 8vo, London, 1849; 4th ed., with a biographical notice by his son, 1860), and "Lectures on the History of France" (2 vols. 8vo, 1851). **II. James Fitzjames**, an English jurist, son of the preceding, born in March, 1829. He graduated at Cambridge in 1852, was called to the bar in 1854, and was legal adviser to the government in India from December, 1869, to April, 1872, when he returned to London. He has published "General View of the Criminal Law of England" (8vo, 1863); "Definition of Murder Considered" (1866); and "Liberty, Equality, Fraternity" (1873). "Essays by a Barrister," reprinted from the "Saturday Review" in 1862, is attributed to him.

**STEPHENS**, an unorganized N. W. county of Texas, intersected in the north by the Clear fork of Brazos river; area, 900 sq. m.; pop. in 1870, 330, of whom 24 were colored. The surface is diversified with hills and valleys, creeks and springs. Stock raising is the chief occupation. The bottom lands of Hubbard's creek are rich.

**STEPHENS**, or **Stephanus** (Fr. *Estienne* or *Étienne*), the name of a French family of printers who flourished during the 16th and 17th centuries. Henry, the founder of the family (born about 1465, died about 1520), established a printing house in Paris in 1502. He published mathematical and theological works,

distinguished for their accuracy. His sons, FRANÇOIS (1502–'50), ROBERT I. (born in Paris in 1503, died in Geneva in 1559), and CHARLES (born in Paris about 1505, died in 1564), were largely engaged in printing. Robert, a man of great learning and industry, in his 20th year published an edition of the Latin New Testament, with some corrections by himself. At his house, which was the resort of the most eminent literary men, Latin was the ordinary language of conversation, even among the children and servants, to whom it was taught by his wife. For many years scarcely a month passed in which some work, generally edited and corrected by himself, did not issue from his press. He is said to have publicly posted proof sheets of his works, with the offer of a premium for the detection of errors. In 1531 he began the publication of his *Dictionarium, seu Thesaurus Linguæ Latinæ*, which he improved in two subsequent editions. New editions have appeared in the present century at London (8 vols. fol., 1815–'25) and Paris (9 vols. fol., 1829–'63). His editions of the Bible with notes brought him into trouble with the Sorbonne, from which he was protected during the life of Francis I., who had appointed him royal printer. After the king's death the Sorbonne caused the sale of his Bibles to be prohibited, and to insure his safety the printer retired to Geneva, where he died, it is said, in the Calvinistic faith. He published at least 11 complete editions of the Bible, in Hebrew, Greek, Latin, and French, besides many separate editions of the New Testament; and 382 other works, mostly of the first importance, came from his press. He first introduced the existing division of the New Testament into verses. Charles, the younger brother of Robert, devoted himself to physical sciences, and for some years practised medicine. He succeeded to his brother's business when the latter retired to Geneva, and was subsequently appointed printer to Henry II. His publications, scientific and classical, are numerous.—HENRY, son of Robert (born in Paris in 1528, died in 1598), spoke Latin with fluency while a child, and throughout his life was a profound student of Greek literature. His establishments were successively in Paris and Geneva; but after the publication of his *Thesaurus Linguæ Græcæ*, the costliness of which confined it to a limited number of purchasers and involved the printer in pecuniary embarrassments, he travelled from city to city, exploring libraries, and collecting an immense amount of material for works which he was projecting, and which he published wherever he happened to be. Among the best known of them are: *Conformité du langage françois avec le grec* (Geneva, about 1565; latest ed., with a notice of his life by Léon Feugère, Paris, 1853), and *La précellence du langage françois* (Paris, 1579; latest ed., with an essay on him and notes by the same author, 1851).—Among others of the family were PAUL, son of the preceding (born in Geneva in 1566, died there in 1627), who succeeded his father in the printing establishment at Geneva, which he conducted for many years; and ANTHONY, his son (born in Geneva about 1592, died at the Hôtel-Dieu in Paris in 1674), who for 50 years conducted a printing house in Paris, but died in great poverty.—See A. A. Renouard, *Annales de l'imprimerie des Estienne* (Paris, 1837; 2d ed., 1843).

**STEPHENS, Alexander Hamilton**, an American statesman, born in Taliaferro co., Ga., Feb. 11, 1812. He graduated at Franklin college, Athens, Ga., in 1832, was admitted to the bar in 1834, and rapidly obtained a large and lucrative practice at Crawfordville. He was elected to the legislature of Georgia in 1836, and was reëlected for five successive terms. In 1842 he was elected to the state senate. In 1843 he was elected as a whig to congress, and held his seat till 1859. In February, 1847, he submitted a series of resolutions in relation to the Mexican war, which afterward formed the platform of the whig party. He opposed the Clayton compromise in 1848, and took a leading part in the compromises of 1850. The passage of the Kansas and Nebraska act of 1854 in the house of representatives was strongly supported by him as chairman of the committee on territories. After the breaking up of the whig party he acted with the democrats. At the close of the 35th congress Mr. Stephens declined to be again a candidate, and on July 2, 1859, he made a speech at Augusta, Ga., announcing his retirement from public life. During the presidential canvass of 1860 he sustained Douglas, and denounced those who advocated a dissolution of the Union in case of Mr. Lincoln's election; and in November, 1860, he made a speech before the legislature of Georgia against secession, on which subject he had an interesting correspondence with Mr. Lincoln in December. He was nevertheless elected to the secession convention which met at Milledgeville, Jan. 16, 1861, and there spoke and voted against the secession ordinance. He was a member of the southern congress which met in Montgomery, Ala., in February, and was elected vice president of the confederacy. On March 21 he delivered a speech in Savannah, in which he declared slavery to be the corner stone of the new government. (See CONFEDERATE STATES.) On April 23, as a special commissioner from the Confederate States, he addressed the convention at Richmond, urging the union of Virginia with the confederacy. He frequently differed from the policy of the Richmond government, especially on the subject of martial law; and on Sept. 8, 1862, he pronounced the appointment by Gen. Bragg of James M. Calhoun as civil governor of Atlanta a palpable usurpation. His letter on this subject created a marked sensation through the south. On Feb. 3, 1865, with R. M. T. Hunter and John A. Campbell, he held an informal conference on a steamer in Hampton roads with Presi-

dent Lincoln and Mr. Seward, which had no practical result. After Lee's surrender Stephens returned to his home in Crawfordville, where on May 11, 1865, he was arrested and sent to Fort Warren in Boston harbor; but on Oct. 11 he was released on parole. On Feb. 22, 1866, he delivered a speech before the legislature of Georgia favoring the restoration policy of President Johnson. In the same month he was elected to the United States senate, but as the state had not complied with the conditions of reconstruction, he was not permitted to take his seat. In 1872 he was elected to congress, and again in 1874, almost without opposition. He has published "A Constitutional View of the Late War between the States, its Causes, Character, Conduct, and Results" (2 vols. 8vo, Philadelphia, 1868-'70), and several speeches.—See "Alexander H. Stephens, in Public and Private," with his letters and speeches before, during, and since the war, by Henry Cleveland (8vo, Philadelphia, 1867).

**STEPHENS, Ann Sophia** (Winterbotham), an American authoress, born in Derby, Conn., in 1813. In 1832 she married Edward Stephens, a printer of Plymouth, Mass., in 1835-'7 edited the "Portland Magazine" and in 1836 the "Portland Sketch Book," and in 1837 removed to New York. She has since edited and contributed to various periodicals, and published many novels, one of the best known of which is "Fashion and Famine" (1854), which appeared in three French versions. A uniform edition of her works was published in Philadelphia in 1869 (14 vols. 12mo). Among her later novels are "Wives and Widows" (1869); "Married in Haste" (1870); "A Noble Woman" (1871); "The Reigning Belle" (1872); "Bellehood and Bondage" (1873); "Lord Hope's Choice," and its sequel, "The Old Countess" (1873); and "Phemie Frost's Experiences" (1874).

**STEPHENS, John Lloyd**, an American author, born in Shrewsbury, N. J., Nov. 28, 1805, died in New York, Oct. 10, 1852. He graduated at Columbia college in 1822, studied law, and practised in New York. After spending two years in travel, he published "Incidents of Travel in Egypt, Arabia Petræa, and the Holy Land" (2 vols. 12mo, 1837), and "Incidents of Travel in Greece, Turkey, Russia, and Poland" (2 vols. 12mo, 1838). He was appointed minister to Central America in 1839, explored the ancient remains of that country, and published "Incidents of Travel in Central America, Chiapas, and Yucatan" (2 vols. 8vo, New York, 1841). In 1842 he again visited Yucatan, and published "Incidents of Travel in Yucatan" (2 vols. 8vo, 1843). These works were illustrated by his fellow traveller Frederick Catherwood of London, and are valuable contributions to American antiquities. Mr. Stephens was active in establishing the first American line of transatlantic steamships. As vice president of the Panama railroad company he negotiated in 1849 the contract with the government of New Granada, was chosen president of the company, and superintended the construction of the road till his death.

**STEPHENSON**, a N. W. county of Illinois, bordering on Wisconsin, intersected by the Pecatonica river and several railroads; area, 550 sq. m.; pop. in 1870, 30,608. The surface is undulating and the soil fertile. The chief productions in 1870 were 529,513 bushels of wheat, 135,362 of rye, 1,615,679 of Indian corn, 960,620 of oats, 165,266 of barley, 261,-110 of potatoes, 36,507 tons of hay, 87,803 lbs. of tobacco, 69,251 of wool, 757,458 of butter, 30,976 of cheese, and 10,855 gallons of sorghum molasses. There were 11,441 horses, 10,723 milch cows, 15,186 other cattle, 18,348 sheep, and 34,437 swine; 14 manufactories of carriages and wagons, 1 of agricultural implements, 3 of furniture, 3 of iron castings, 8 of saddlery and harness, 3 of woollen goods, 3 breweries, and 1 tannery. Capital, Freeport.

**STEPHENSON. I. George**, an English railway engineer, born at Wylam, Northumberland, June 9, 1781, died at Tapton park, near Chesterfield, Derbyshire, Aug. 12, 1848. For several years he was employed at various collieries as fireman, and afterward as plugman, and gradually acquired so complete a knowledge of the engine as to be able to take it apart and make any ordinary repairs. At 18 he could not read; but within two years, by attending night schools, he was able to read, write, and cipher with tolerable facility. In 1805 he removed to Killingworth colliery, and about this time was desirous of emigrating to the United States, but was unable to raise money for his passage and outfit. He continued to work in different collieries, and in his leisure hours studied mechanics and engineering, mended clocks and shoes, cut out clothes for the miners, and turned his hand to other useful occupations. His skill in repairing engines and his improvements upon old machinery led in 1812 to his appointment as enginewright at Killingworth, at a salary of £100 a year. Besides erecting a winding engine for drawing up coal, and a pumping engine, he projected and laid down a self-acting incline along the declivity of the Willington ballast quay, so arranged that full wagons descending to the vessels drew up the empty ones. But the construction of an efficient and economical locomotive steam engine mainly occupied his attention, and in July, 1814, he completed one which worked successfully on the Killingworth railway, and proved the best yet constructed. It was the first locomotive made with smooth wheels, for he rejected the contrivances which Trevithick, Blenkinsop, and others had thought necessary to secure sufficient adhesion between the wheels and the rails. While engaged in plans for an improved engine, his attention was attracted to the increase in the draught of the furnace obtained by turning the waste steam up the chimney, at first practised solely in the desire to lessen the noise caused by the

escape of the steam. Hence originated the steam blast, the most important improvement in the locomotive up to that time, and it was embodied in Stephenson's next engine, completed in 1815. For some years Stephenson had been experimenting with the fire damp in the mines, and in 1815 he completed a miner's safety lamp, which is still in use in the Killingworth collieries. The invention of a safety lamp by Sir Humphry Davy was nearly simultaneous, and to him the mining proprietors presented a service of plate worth £2,000, at the same time awarding £100 to Stephenson. This led to a protracted discussion as to the priority of the invention, and in 1817 Stephenson's friends presented £1,000 to him. Having brought the locomotive to a considerable degree of perfection, Stephenson next turned his attention to the improvement of railways, his opinion being that both were parts of one mechanism, and that the employment of steam carriages on common roads was impracticable. For the purpose of making railways solid and level, and preventing jerks at the junction of the rails, he took out in 1816 a patent for an improved rail and chair, and recommended the employment of heavier rails and the substitution of wrought for cast iron. In connection with these improvements he added considerably to the lightness and strength of the locomotive, simplified the construction of the working parts, and substituted steel springs for the small cylinders on which the boiler had at first rested. His next important undertaking was the construction of a railway eight miles in length for the owners of the Hetton colliery, which was successfully opened on Nov. 18, 1822, the level parts being traversed by five of Stephenson's locomotives, while stationary engines were employed to overcome the heavy grades. In 1820 an act of parliament was obtained for a railway between Stockton and Darlington, of which Stephenson, who made the preliminary surveys and specifications, was in 1823 appointed engineer. The line was intended to be worked by stationary engines for the steep gradients, with horse power on the level portions; but at Stephenson's urgent request the act was amended so as to permit the use of locomotives on all parts of the road, which was opened Sept. 27, 1825. In 1824, in connection with Edward Pease, he opened an establishment for the manufacture of locomotives at Newcastle-upon-Tyne. In 1825 he was appointed principal engineer of the Liverpool and Manchester line, made the preliminary surveys, and in June 1826, began the construction of the road, which employed him during the next four years. Of the engineering difficulties successfully overcome, the most important was the crossing at Chatmoss, a bog 4½ m. in length, on which the road was made to float. While this road was building, the most eminent engineers persisted in recommending stationary engines in place of locomotives, which they declared unsafe and incapable of attaining high speed; and the clumsy expedient of a series of stationary machines 1½ m. apart, dragging the trains by ropes, would have been adopted but for the energy of Stephenson and a few of his friends. He finally prevailed on the directors to offer a prize of £500 for the most effective locomotive engine for the purposes of the road; and at a trial which took place near Liverpool, Oct. 6, 1829, his engine, the Rocket, constructed by himself and his son Robert, was adjudged to be the best of the four entered, having averaged a speed of 14 m. an hour, and even attained one of 29 m. The distinguishing features of the Rocket, the first high-speed locomotive of the standard modern type, were the multitubular boiler, which was not Stephenson's invention, but was first applied by him to locomotives; the blast pipe; and the direct connection of the steam cylinders to one axle and one pair of wheels. At the opening of the road, Sept. 15, 1830, eight locomotives constructed at the Stephenson works were employed, and Mr. Huskisson, having been accidentally struck down and fatally injured by the Rocket, was conveyed in the Northumbrian, driven by George Stephenson, from Parkside to Eccles, 15 m., at the then unprecedented rate of 36 m. an hour. Stephenson was almost incessantly employed for the next 15 years on new roads, and was called three times to Belgium and once to Spain as a consulting engineer. With his increasing wealth he also engaged extensively and profitably in coal mining and lime works, particularly in the neighborhood of Tapton park, an elegant seat in Derbyshire, where he passed his latter years. He declined the honor of knighthood.—See "Life of George Stephenson," by Samuel Smiles (8vo, London, 1857; 8th ed., including Robert Stephenson, 1864; again enlarged, 1868). **II. Robert,** a railway engineer, son of the preceding, born at Willington, near Newcastle-upon-Tyne, Oct. 16, 1803, died in London, Oct. 12, 1859. After several years' schooling at Newcastle, and a preparatory training in the collieries, he went in 1822 to the university of Edinburgh. He returned home in 1823, and accepted in 1824 an engagement as engineer in South America. In 1827, after a short tour in the United States and Canada, he returned to England, and was employed in the construction of the Liverpool and Manchester railway, and in connection with his father in the improvement of locomotives. After being engaged on several minor railway lines, he was appointed engineer of the London and Birmingham road, which under his direction was completed in 1838; and thenceforth for many years he was almost exclusively occupied with similar undertakings at home and abroad. Among his most remarkable works are the high level bridge over the Tyne at Newcastle, the viaduct over the Tweed valley at Berwick, the Conway bridge, and above all the Britan-

nia tubular bridge across the Menai straits. (See Bridge, vol. iii., p. 275.) He was also employed on railways in Belgium, Sweden, Norway, Italy, France, and other parts of Europe, and visited Egypt several times to superintend the construction of a road between Alexandria and Cairo, on the line of which are two tubular bridges, traversed by trains on the roof instead of the inside, as in the case of the Britannia bridge. He also designed an immense bridge across the Nile at Kaffre Azzayat, and the great Victoria tubular bridge which crosses the St. Lawrence near Montreal, and was formally opened in the summer of 1860. From 1847 till his death he represented the Yorkshire borough of Whitby in parliament. He was a member of several scientific bodies, received a great gold medal of honor from the French industrial exposition of 1855, and from 1855 to 1858 was president of the institute of civil engineers. He published "Description of the Locomotive Steam Engine" (4to, London, 1838); "Report on the Atmospheric Railway System" (4to, 1844); and "The Great Exhibition, its Palace and Contents" (12mo, 1851). Besides Smiles's biography, his life has been written by J. C. Jeaffreson and W. Pole (2 vols., London, 1864).

**STEREOSCOPE** (Gr. στερεός solid, and σκοπέιν, to see), an instrument by aid of which the two eyes view two different pictures of the same object and combine them into one having the appearance of solidity. This illusion is produced by presenting to the right eye a picture which represents the object in perspective as it would appear to that eye alone, and to the left eye the picture of the object as seen by the left eye. If these two pictures exactly represent the object as seen respectively by the right and the left eye, which can readily be accomplished by means of photography, we shall, on looking into the stereoscope, receive the same impression of solidity or relief as is given when both eyes look at the real object. One who has sufficient power of directing the movements of his eyes does not need an instrument to aid him in combining the two pictures on a stereoscopic slide. It is only required that the right eye and the left shall be respectively directed to corresponding points on the right-hand and left-hand pictures. It is said that a stereoscope as just described was conceived by Prof. Elliot of Edinburgh in 1834, but was not constructed by him till 1839, after Sir Charles Wheatstone had in 1838 invented and exhibited his reflecting stereoscope. In Wheatstone's instrument the observer looks with his left eye into a mirror at *a*, fig. 1, and with his right eye into a mirror at *b*. These mirrors are inclined at an angle of about 45°, and hence reflect into the eyes the two pictures placed at *k* and *g*. These pictures therefore appear at the same place behind the two mirrors, and give the observer the impression that he is looking at an object or group of objects having solidity, or the third dimension. In 1849 Sir David Brewster invented a refracting stereoscope. This is more convenient than Wheatstone's, but does not give such well defined effects as the reflecting instrument. In Brewster's ste-

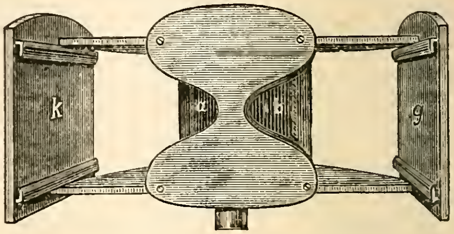

Fig. 1.—Wheatstone's Stereoscope.

reoscope the two pictures are placed side by side, and are separated from each other by a partition, S, fig. 2, so that the right eye can only view the right-hand picture and the left eye the left-hand one. These two pictures are

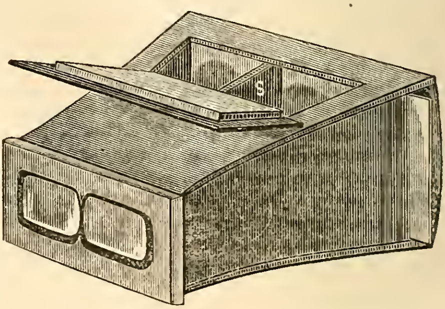

Fig. 2.—Brewster's Stereoscope.

observed through two lenticular prisms, L and R, fig. 3, which not only slightly magnify the pictures, but also cause them to overlap each other; and thus we see in the middle of the instrument one picture which appears in relief.

Fig. 3.—Section of the Eye Pieces.

These effects of solidity can readily be exaggerated by taking the two pictures by means of two photographic cameras, the distance between the centres of whose lenses is greater than that between the centres of the human eyes. The explanation of the illusions of the stereoscope is contained in the explanation of the fact that binocular vision gives us the perception of the third dimension of extension in all objects not over 200 ft. distant from the eyes; for in the stereoscope we have the images formed on the retina of the right eye and of the left similar to the images that would be formed in the eyes if real solid objects were before us, having the sizes and the situations

that they appear to have in the stereoscopic illusion in the instrument; also, the axes of the eyes are inclined to each other in the same manner when looking in the stereoscope as they would be if they regarded the above mentioned group of solid objects. Hence the eye is affected exactly as when it views these real objects, and a stereoscopic perception is the effect. Indeed, a simple rule for all illusions of sight, as Helmholtz concisely states, is "that we always believe that we see such objects as would, under conditions of normal vision, produce the retinal image of which we are actually conscious." The reason that a stereoscopic perception is obtained when we look at a near object is due to the fact that the impressions produced by the two different pictures of this object on the retina, and the muscular adjustment of the ocular axes so that they converge to the same point of the object, are translated, through the experience of touch, as effects belonging to solidity. Some have imagined that they had explained stereoscopic perception by the fact that the axes of the eyes converge to point after point on the object in rapid succession, and thus, as it were, triangulate the positions of these points by a series of visual triangles, which have for their base the distance separating the yellow spots, or *maculæ luteæ*, on the retinas of the eyes (see Eye, fig. 1), and for sides the lines drawn from these spots to the various observed points of the object. But Dove showed that the stereoscopic perception is obtained when we illuminate the pictures in the stereoscope by the flash of a Leyden jar; and Prof. Rood has shown that the duration of this illumination is only four billionths of a second, a duration altogether too short to allow the eyes time to make any motion. Others have maintained that a combination of the impressions produced upon both retinas takes place, and thus the two plane retinal pictures are fused into a stereoscopic perception; but the retinal impressions do not combine, for Dove has shown that when dull black is alone viewed with one eye, while white is regarded with the other, the perception produced is similar to that of the metallic surface of graphite; whereas the real combined sensation of these impressions is a dull gray. From these and many other experiments we learn that "two distinct sensations are transmitted from the two eyes, and reach the consciousness at the same time and without coalescing; that accordingly the combination of these two sensations into the single picture of the external world of which we are conscious in ordinary vision is not produced by any anatomical mechanism of sensation, but by a mental act."—See "The Stereoscope," by Sir David Brewster (London, 1856), and "Recent Progress of the Theory of Vision," by Helmholtz, published in his "Popular Lectures on Scientific Subjects" (New York, 1874).

**STEREOTYPE.** See Printing, vol. xiii., p. 850.

**STERLING.** See Pound Sterling.

**STERLING,** a city of Whitesides co., Illinois, on the N. bank of Rock river, and on the Chicago and Northwestern and the Rockford, Rock Island, and St. Louis railroads, at the terminus of the Rock River branch of the Chicago, Burlington, and Quincy line, 110 m. W. of Chicago and 28 m. E. of the Mississippi river; pop. in 1860, 2,428; in 1870, 3,998; in 1875, 5,312. It is lighted with gas, and is supplied with water by the Holly system of works and by an artesian well 1,650 ft. deep, discharging 700 barrels an hour. It is chiefly devoted to manufacturing. The river at this point is spanned by a dam of solid masonry, 1,100 ft. long and 7 ft. high, which with the 9 ft. natural fall of the rapids above affords an immense water power. The value of the manufactures of Sterling and Rock Falls (opposite) in 1874 was about $4,250,000, and the number of hands employed upward of 1,000. The articles are principally of wood, including agricultural implements, school furniture, feed mills, pumps, burial cases, carriages and wagons, building materials, butter tubs, washing machines, barrels, hedge trimmers, tables, mittens, machinery, mineral paint, paper, &c. There are five flour mills, a distillery (the largest in the United States), two tanneries, and a pork-packing establishment. Sterling has a national bank, three public school houses, two reading rooms, a public library, two weekly newspapers, and 12 churches. It was laid out in 1836, and incorporated as a city in 1857.

**STERLING, John,** a British author, born at Kames castle, isle of Bute, July 20, 1806, died at Ventnor, isle of Wight, Sept. 18, 1844. He was educated at Glasgow and Cambridge universities, in 1827 went to London, and for a few months in 1828 edited with F. D. Maurice the "Athenæum." In 1830–'31 he passed 15 months on St. Vincent island, West Indies, for his health, the state of which required intervals of residence in the south of France, Madeira, and Italy through the rest of his life. In 1834 he took deacon's orders and became curate to his former college tutor J. C. Hare, rector of Hurstmonceaux, Sussex; but in February, 1835, he went to London to devote himself to literature. In August, 1838, he founded the Anonymous club, afterward called the Sterling club. Among the members were Carlyle, Tennyson, Moncton Milnes, John Stuart Mill, J. C. Hare, C. L. Eastlake, Sir Edmund Head, and G. C. Lewis. Sterling published "Arthur Coningsby," a novel (London, 1833); "Minor Poems" (1839); "The Election," a poem (1841); and "Strafford," a drama (1843). After his death appeared "Essays and Tales," collected from various reviews, with a memoir by J. C. Hare (2 vols. 8vo, 1848); "Life of John Sterling," by Thomas Carlyle (1851); "Twelve Letters by John Sterling," edited by W. Coningham (1851); and "The Onyx Ring," from "Blackwood," with a biographical preface by Charles Hale (Boston, 1856).

**STERN, Daniel.** See AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY.

**STERNBERG,** a town of Moravia, 10 m. N. of Olmütz; pop. in 1870, 13,479. It has an old palace and a military school, and is the great centre of the Moravian manufacture of cotton and linen goods.

**STERNE, Laurence,** an English author, born in Clonmel, Ireland, Nov. 24, 1713, died in London, March 18, 1768. His parents were English, and his father, Roger Sterne, was a lieutenant in Handaside's regiment, the movements of which, "from barrack to transport, from Ireland to England," young Laurence followed until his 10th year, when he was put to school at Halifax in England. He graduated at Cambridge in 1736, took orders, and was presented to the living of Sutton in Yorkshire. In 1741 he married, and about the same time obtained the living of Stillington, adjoining Sutton, while his uncle procured him a prebend in York cathedral. For nearly 20 years his only acknowledged publications were two sermons, although he wrote political paragraphs for the newspapers, and is said to have conducted for some time a periodical electioneering paper in the whig interest. In 1759 he published at York, under the pseudonyme of "Mr. Yorick," the first two volumes of "Tristram Shandy," which were reprinted in London early in 1760. The 3d and 4th volumes appeared in 1761, the 5th and 6th in 1762, the 7th and 8th in 1765, and the 9th in 1767. Long before the completion of the work, the charm and the novelty of the style, the whimsical digressions, the exquisite touches of pathos and humor, and its many admirably conceived characters, had taken an extraordinary hold upon the public, and Sterne ranked with Fielding and Richardson and Smollett as a great writer of prose fiction. He was lionized in London, where people were invited a fortnight in advance to dine with him; and Boswell has recorded Johnson's remark that "the man, Sterne, had engagements for three months." The erudition which so greatly astonished the not very learned readers who welcomed the appearance of "Tristram Shandy" will, however, scarcely stand the test of modern criticism, and it has been shown by Dr. Ferriar, in his "Illustrations of Sterne" (1798), that the quaint imagery and the quainter conceits scattered through the book were largely borrowed from Rabelais, Burton, and other authors. But after making liberal allowances for plagiarisms, his Uncle Toby, Corporal Trim, Mr. Shandy, Dr. Slop, and Widow Wadman must be considered among the most original personages in fiction. In 1760 and 1766, during the publication of "Tristram Shandy," appeared four volumes of sermons, also by "Mr. Yorick." In 1760 Sterne received an additional living at Coxwold in Yorkshire, and took a house in York for his wife and daughter, but passed most of his own time in London or on the continent. In 1762 he visited France, and in 1764 went to Italy for his health. Returning to York in 1767 he wrote the first and only part of "The Sentimental Journey," and took it to London for publication. Soon after its appearance he died without a friend near him, and was privately buried at Edgeware. In 1775 his daughter Lydia published three volumes of his "Letters to his Friends," accompanied by a short autobiographical memoir; and in the same year appeared "Letters to Eliza," consisting of ten letters addressed by Sterne in March and April, 1767, to "Mrs. Elizabeth Draper, wife of Daniel Draper, Esq., counsellor at Bombay, and at present chief of the factory at Surat," and another collection of letters in one volume. "Seven Letters by Sterne and his Friends," edited by W. Durrant Cooper, were privately printed in 1844. The most complete edition of Sterne's works was edited by James P. Browne, M. D., and comprises in an appendix 13 letters hitherto unpublished (4 vols. 8vo, London, 1873).—Of the personal character of Sterne, as seen in his life and letters, no favorable impression can be formed. The latter show him to have been indifferent to the duties of his profession, lax in principle, a bad husband, a faithless lover, offering his affections to two or three married women at once, the dupe of every coarse flatterer, and false to his professions of virtue or sensibility.

**STERNHOLD, Thomas,** an English writer, born in Hampshire about 1500, died in August, 1549. He was groom of the robes to Henry VIII. and Edward VI., and was noted at court for his poetical talents and piety. He undertook a translation into metre of the Psalms of David, but completed only 37, printed in 1549, after his death, with seven by John Hopkins, under the title of "All such Psalms of David as Thomas Sternholde, late Grome of the Kinges Majestyes Robes, did in his lyfe-tyme drawe into Englyshe Metre." The version was completed and published in 1562 as "The Whole Book of Psalms, collected into English Metre by T. Sternhold, J. Hopkins, and others, conferred with the Ebreu; with apt Notes to sing them withal;" under which title it was annexed to the "Book of Common Prayer," and was used till superseded by Tate and Brady's collection (1696). Sternhold was also the author of "Certain Chapters of the Proverbs of Solomon, drawen into Metre" (1549).

**STESICHORUS,** a Greek lyric poet, born in Himera, Sicily, in 632 B. C., died about 555. He is said to have been educated at Catana, and to have been on friendly terms with Phalaris of Agrigentum. It is said that his real name was Tisias, and that he received the name of Stesichorus, "chorus leader," for his efforts in choral poetry, for which he invented the divisions of strophe, antistrophe, and epode. He wrote in the Doric dialect. His poems were chiefly on heroic subjects, although he wrote

many on themes more purely lyrical. He was the first of the Greeks who composed erotic poems. The fragments of his writings have been collected by Kleine (*Stesichori Himerensis Fragmenta*, Berlin, 1828); by Schneidewin in his *Delectus Poesis Græcorum* (Göttingen, 1839); and by Bergk in *Poetæ Lyrici Græci* (3d ed., Leipsic, 1867).

**STETHOSCOPE.** See AUSCULTATION.

**STETTIN,** a town of Prussia, capital of the province of Pomerania, on the left bank of the Oder, 76 m. N. E. of Berlin; pop. in 1871, 76,149. The river is crossed by two bridges, and the town and suburbs are defended by walls, a citadel, and several forts and outworks. Stettin has several fine squares, with monuments of Frederick the Great and Frederick William III., is generally well built, and possesses a school of navigation, with an observatory. The ancient castle of Stettin, which was the residence of the dukes of Pomerania, contains a collection of northern antiquities. Chemical products, woollen, linen, cotton, sugar, anchors, &c., are manufactured. The imports amounted in 1873 to 87,631,985 thalers, and the exports to 30,394,333 thalers. The registered shipping included 30 sea-going steamers and 178 other vessels. Vessels drawing over 15 ft. cannot ascend the Oder, and discharge at Swinemünde on the Baltic, 35 m. distant. The town was a considerable place as early as the 9th century, and was a member of the Hanseatic league. It belonged to Sweden from 1648 to 1720.

**STEUART, Sir James Denham,** a Scottish political economist, born in Edinburgh in October, 1713, died Nov. 26, 1780. He was educated at the university of Edinburgh, and in 1734 was admitted to the Scottish bar. Although of a whig family, he became imbued with Jacobite doctrines. Having declared for the young pretender in 1745, he was sent by him on a mission to the court of France, and the consequence was a compulsory absence from Great Britain for 17 years. In 1763 he was permitted to return to Scotland, and in 1771 he obtained a free pardon. While abroad he published works in French and German on chronology and money, and in 1767 produced his "Inquiry into the Principles of Political Economy" (2 vols. 4to, London). He also wrote "The Principles of Money applied to the Present State of the Coin of Bengal" (1772), "A Plan for introducing an Uniformity of Weights and Measures" (1790), &c. A complete edition of his works was edited by his son, Gen. Sir James Denham Steuart (6 vols., 1805). (See POLITICAL ECONOMY, vol. xiii., p. 668.)

**STEUBEN. I.** A S. W. county of New York, bordering on Pennsylvania, drained by Chemung, Canisteo, Tioga, and Conhocton rivers; area, 1,425 sq. m.; pop. in 1870, 67,717; in 1875, 73,923. The surface is broken and the soil generally fertile. Iron ore and good building stone are found. There are two or three small lakes, and Keuka (formerly Crooked) lake is partly within the county. It is traversed by the Erie railway and branches, and by the Corning, Cowanesque, and Antrim railroad. Considerable lumber is exported. The chief productions in 1870 were 540,557 bushels of wheat, 72,792 of rye, 344,299 of Indian corn, 1,538,117 of oats, 207,024 of barley, 286,102 of buckwheat, 543,687 of potatoes, 169,294 tons of hay, 150,540 lbs. of tobacco, 700,704 of wool, 62,118 of hops, 112,228 of maple sugar, 87,013 of honey, 2,834,636 of butter, and 233,438 of cheese (not including factory cheese). There were 15,642 horses, 30,329 milch cows, 2,993 working oxen, 22,717 other cattle, 145,645 sheep, and 15,430 swine; 5 manufactories of agricultural implements, 48 of carriages and wagons, 7 of cheese, 16 of cooperage, 15 of furniture, 1 of glass ware, 8 of iron castings, 19 of tanned and 9 of curried leather, 4 of machinery, 22 of saddlery and harness, 2 of wine, 2 woollen mills, 3 distilleries, 5 breweries, 89 saw mills, and 18 flour mills. Capitals, Bath and Corning. **II.** A N. E. county of Indiana, bordering on Ohio and Michigan, and intersected by the St. Joseph's and Pigeon rivers; area, 340 sq. m.; pop. in 1870, 12,854. The surface is prairie and woodland, and the soil is fertile. The chief productions in 1870 were 232,816 bushels of wheat, 352,200 of Indian corn, 97,719 of oats, 90,020 of potatoes, 16,861 tons of hay, 117,337 lbs. of wool, 289,472 of butter, and 3,313 of sorghum molasses. There were 4,122 horses, 3,823 milch cows, 5,838 other cattle, 32,387 sheep, and 11,332 swine. The Fort Wayne, Jackson, and Saginaw railroad passes through the capital, Angola.

**STEUBEN, Frederick William Augustus,** baron, an American soldier, born in Magdeburg, Prussia, Nov. 15, 1730, died near Utica, N. Y., Nov. 28, 1794. He was educated at the Jesuit colleges of Neisse and Breslau, and became a cadet in an infantry regiment in 1747, an ensign in 1749, and a lieutenant in 1753. In 1757 he distinguished himself at the battles of Prague and Rossbach, in 1758 was appointed an adjutant general, and was in the battles of Kay and Kunersdorf in 1759, in the latter of which he was wounded. In 1762 he was made adjutant general in the king's staff. He was a member of Frederick's select academy of young officers who were under his special instruction; and after the siege of Schweidnitz, in which he participated, the king presented him with a valuable lay benefice. At the close of the seven years' war he accompanied to several courts of Europe the prince of Hohenzollern-Hechingen, who in 1764 made him grand marshal and general of his guard. In 1777, while on a visit to France, he was induced by the count St. Germain to go to America. He arrived at Portsmouth, N. H., Dec. 1, and immediately wrote to congress and to Gen. Washington, tendering his service as a volunteer. Shortly afterward he went to York, Pa., where congress was in session, was di-

rected to join the army under Washington, and during the winter arrived at Valley Forge. On May 5, 1778, he was appointed inspector general with the rank of major general, and in June he was at the battle of Monmouth. He prepared a manual for the army, which was approved by congress in 1779, and introduced the most thorough discipline. In 1780 he was a member of the court martial on the trial of Major André. In the same year he was placed in command of the troops in Virginia, and in January following was active in harassing the British forces under Benedict Arnold. In the summer he was attached to Gen. Lafayette's division, and took part in the siege of Yorktown. In 1790 congress voted him a life annuity of $2,500. Several of the states passed resolutions acknowledging his services, and voted him tracts of land. New York presented him with 16,000 acres near Utica, forming a township called from him Steuben, where he passed the remainder of his life, giving portions of the land to his aids, and leasing the remainder. His life has been written by Francis Bowen in Sparks's "American Biography," and by Friedrich Kapp (New York, 1860).

**STEUBENVILLE,** a city and the capital of Jefferson co., Ohio, on the Ohio river, here crossed by a railroad bridge, 22 m. N. by E. of Wheeling, W. Va., 35 m. W. of Pittsburgh, Pa., and 125 m. E. by N. of Columbus; pop. in 1860, 6,154; in 1870, 8,107; in 1875, locally estimated at 15,000. It stands on an elevation on the right bank of the river, is well laid out and substantially built, is surrounded by a rich farming and stock-growing country, and is the centre of an important trade. Abundance of excellent coal is found in the neighborhood, and there are eight shafts within the city limits. The court house is the finest in eastern Ohio. The city has water works, gas works, and two steam fire engines. The Pittsburgh, Cincinnati, and St. Louis railroad, and the river division of the Cleveland and Pittsburgh railroad, intersect here. The river trade is extensive. The chief manufactories are two founderies and machine shops, two rolling mills, a nail mill, two engine and boiler works, three blast furnaces, a flouring mill, two woollen mills, a paper mill, three breweries, and two glass works. There are two national banks, two private banks, two savings institutions, nine public schools, including a high school, a female seminary, a Roman Catholic school, two daily and two weekly newspapers, and 18 churches (Christian, Congregational, Episcopal, Lutheran, Methodist, Presbyterian, and Roman Catholic).—A blockhouse was erected on the site of Steubenville in 1786, and in 1787 a fort was built and named in honor of Baron Steuben; but the place was not permanently settled till 1797. It was incorporated as a city in 1851, and in 1871 its limits were extended.

**STEVENS.** I. A W. county of Minnesota, intersected by the Pomme de Terre river, a tributary of the Minnesota; area, 576 sq. m.; pop. in 1870, 174. The surface is rolling and is studded with numerous lakes. The soil is productive. The St. Paul and Pacific railroad traverses it. **II.** An unorganized S. W. county of Kansas, bordering on Indian territory; area, 720 sq. m. It is intersected by the Cimarron river. The surface is undulating. **III.** A N. W. county of Dakota, bounded S. W. by the Missouri river, recently formed and not included in the census of 1870; area, about 3,100 sq. m. It is mostly occupied by the Plateau du Coteau du Missouri. The N. E. corner is intersected by Mouse river. **IV.** The N. E. county of Washington territory, bordering on British Columbia and Idaho, bounded S. in part by the Snake river, W. in part by the Cascade mountains, and intersected by the Columbia; area, 28,000 sq. m.; pop. in 1870, 734. Lake Chelan is in the W. part, and the county is watered by Clarke's fork, the Okinakane, Palouse, Spokane, and other streams. There are broad plains and rugged mountains, with some barren places, but the proportion of valuable land is large, and much of it is very fertile. The climate is mild. There are gold mines on the bars of the Columbia and lateral streams. The chief productions in 1870 were 8,791 bushels of wheat, 12,504 of oats, 3,825 of potatoes, and 791 tons of hay. There were 415 horses, 1,100 cattle, and 485 swine. Capital, Colville.

**STEVENS, Abel,** an American clergyman, born in Philadelphia, Jan. 19, 1815. He studied at Wesleyan university, Middletown, Conn., and in 1834 was settled as pastor of a Methodist Episcopal church in Boston. In 1837 he travelled in Europe, and on his return was stationed in Providence, R. I. In 1840 he took editorial charge of "Zion's Herald" in Boston, and in 1852 of the "National Magazine," New York; in 1855 revisited Europe, and on returning in 1856 was elected editor of the "Christian Advocate and Journal," New York. He afterward became joint editor of "The Methodist," from which he retired in 1874. Dr. Stevens has published "Memorials of the Introduction of Methodism into New England" (1848); "Memorials of the Progress of Methodism in the Eastern States" (1852); "Church Polity;" "The Preaching required by the Times" (1855); "Sketches and Incidents, a Budget from the Saddle Bags of an Itinerant;" "The Great Reform;" "History of the Religious Movement of the Eighteenth Century called Methodism" (3 vols., 1858–'61), which has been several times edited and reprinted in England; "Life and Times of Nathan Bangs, D. D." (1863); "History of the Methodist Episcopal Church in the United States of America" (4 vols., 1864–'7); "The Centenary of American Methodism" (1866); "The Women of Methodism" (1866); and "Compendium of the History of Methodism" (1868).

**STEVENS, Alexander Hodgdon,** an American surgeon, born in New York in 1789, died there, March 30, 1869. He graduated in medicine in 1815 at the university of Pennsylvania, and

became surgical dresser and afterward house surgeon in the New York hospital. In 1817 he was appointed attending surgeon there, and in 1839 consulting surgeon. He was professor of the principles and practice of surgery in the college of physicians and surgeons, New York, from 1826 to 1837, and of clinical surgery from 1837 to 1839. He was also president of the college from 1843 to 1855. In 1848 he was chosen president of the state medical society.

**STEVENS, Alfred** (two). See p. 898.

**STEVENS, George Alexander,** an English author, born in London in the early part of the 18th century, died at Baldock, Hertfordshire, Sept. 6, 1784. He was at first a strolling actor, and acquired reputation as a writer of burlesques and of comic songs. In 1760 he published a novel, "The History of Tom Fool," and a few years later produced an entertainment entitled "A Lecture on Heads." He also published a volume of "Songs, Comic and Satirical" (1772); and after his death appeared "The Adventures of a Speculist, compiled from the Papers of G. A. Stevens, with his Life, a Preface, and Notes" (1788).

**STEVENS. I. John,** an American inventor, born in New York in 1749, died in Hoboken, N. J., in 1838. He early engaged in solving the problem of steam navigation, and in a memorial to the legislature of New York in 1789 stated that he had perfected his plans. In 1804 he launched a propeller, using the screw, and in 1805 he employed twin screws. He completed the steamboat Phœnix in 1807, and being prevented by Fulton's monopoly from navigating the Hudson, he sent the vessel to sea and up the Delaware. Her engines were high-pressure condensing, and the boilers of the kind now called sectional. Neither these nor either single or twin screws were generally employed by engineers until many years afterward. In 1812 he designed a circular iron-clad or revolving steam battery with armor plating, substantially the same as those recently designed by the late John Elder, and like those now constructing for the Russian navy; and in the same year he published a pamphlet on railroads, indicating the mode of applying steam, calculating their cost, and predicting the speed of trains. He planned the Camden and Amboy railroad. **II. Robert Livingston,** son of the preceding, born in Hoboken, N. J., in 1788, died there, April 20, 1856. He had charge of his father's steamboat the Phœnix in its passage to the Delaware, and in 1808 introduced concave water lines in her hull, the first application of the wave line to ship building; and he was afterward largely engaged in building steamboats. In 1813-'14 he invented and sold to the government percussion elongated shells for smooth-bore guns; in 1818 he burned anthracite coal in a cupola furnace, and soon after used it in his steamers. In 1822 he substituted the skeleton wrought-iron working beam for the heavy cast-iron one before in use; and during the next 27 years he made numerous other improvements in steam machinery and navigation. In 1836 he introduced the T rail on the Camden and Amboy railroad, of which he was president for many years. In 1842 he was commissioned by the United States government to build an iron-plated war steamer or battery, to be shell-proof and driven by screws. (See IRON-CLAD SHIPS.) In consequence of a change of his plan, it was unfinished at his death. **III. Edwin Augustus,** brother of the preceding, born in Hoboken in 1795, died in Paris, France, Aug. 7, 1868. With his brothers he established lines of steam passenger and tow boats on the Hudson and other rivers. He also made several inventions and improvements in machinery and naval architecture. At the opening of the civil war he endeavored, in conjunction with his brother James C., to induce the government to take and put in service the iron-clad battery begun by Robert L. Stevens, offering to complete the ship at their own expense, payment only to be made in case of her success. For the purpose of showing the feasibility of their plans, they fitted out the small iron-clad Naugatuck, and sent her into action; she took part in the engagement on the James river, and rendered valuable assistance. The government declined the offer, and Edwin A. Stevens left at his death $1,000,000 for the completion of his brother's plans. The amount proved insufficient, however, and the vessel was sold to the United States navy in November, 1874, by the state of New Jersey, to which he had bequeathed it. Congress having failed to make the appropriation for the purchase, the vessel still remains (1876) in dock at Hoboken. Mr. Stevens possessed an immense fortune. He endowed the Stevens high school at Hoboken, and at his death left nearly $1,000,000 for the purpose of founding the Stevens institute of technology. (See HOBOKEN.)

**STEVENS. I. Joseph,** a Belgian painter, born in Brussels about 1819. He is the son of a French officer, is self-taught, and resides alternately at Paris and Brussels, and is distinguished for his pictures of animals, especially dogs, and also for his genre paintings. **II. Alfred,** a Belgian painter, brother of the preceding, born in Brussels in 1828. He completed his studies under Roqueplan in Paris, and has made himself known by his genre pictures, such as "The Visit," "The Pink Lady," and "The Love of Gold."

**STEVENS, Thaddeus,** an American statesman, born at Peacham, Caledonia co., Vt., April 4, 1793, died in Washington, D. C., Aug. 11, 1868. His parents were poor, and he was lame and sickly from childhood; but he qualified himself by hard study to enter college, and graduated with honor at Dartmouth in 1814. He went immediately to York, Pa., where he taught school and studied law, and soon obtained a large practice. He kept aloof from politics till the election of Jackson in 1828, against whom he took part with great ardor, and became an

active member of the whig party. In 1833 and for several succeeding years he was a member of the Pennsylvania legislature, and he became distinguished by his opposition to slavery. He was appointed a canal commissioner in 1838, and rendered important services to the state in the promotion of her system of internal improvements. In 1842 he removed to Lancaster, and for six years devoted himself to his profession. He was elected representative in congress in 1848 and reëlected in 1850. He strongly opposed the fugitive slave law and the Kansas-Nebraska bill. He was again elected to congress in 1858, and held his seat till his death. In his latter years in congress he was a recognized chief of the republican party, and took the lead in all measures for emancipating and arming the negroes and for giving them citizenship. He also advocated acts of confiscation and other severe measures against the confederates; and he was chairman of the managers for the impeachment of President Johnson.

**STEVINUS,** or **Stevin, Simon,** a Flemish mathematician, born in Bruges about 1550, died at the Hague about 1630. The particulars of his life are unknown. In 1586 he published in Dutch a work on "Statics and Hydrostatics" and "A new System of Fortification;" in 1589 a tract on the motion of the heavens; and in 1599 a treatise on navigation (translated into Latin by Grotius, Leyden, 1624). In 1605 Willebrord Snell translated into Latin most of the works of Stevinus, but died before completing the translation. In 1634 Albert Girard published at Leyden all his works in French, including a collection of geometrical problems.—See *Simon Stevin*, by Quetelet (Brussels, 1845).

**STEWARD, Lord High,** in England, the highest officer under the crown, who was formerly known by the Latin title of *magnus seneschallus.* Under the Plantagenets the office was hereditary, and was held by the house of Leicester, until forfeited by Simon de Montfort. Since the reign of Henry IV. it has been abolished as a permanent dignity, and is conferred for some special occasion, as a trial before the house of peers or a coronation. The lord high steward presides at the former, and at the close of the proceedings breaks his wand and dissolves the court.—The office of steward, or stewart, also existed from early times in Scotland, and gave name to the royal family of Stuart, in which it was hereditary from the time of David I. (1124–'53) till the accession to the throne of Robert (II.) Stuart, grandson of King Robert Bruce, in 1371.

**STEWART. I.** A S. W. county of Georgia, bounded W. by the Chattahoochee river, which separates it from Alabama, and drained by several of its tributaries; area, about 500 sq. m.; pop. in 1870, 14,204, of whom 9,100 were colored. The soil is fertile. The chief productions in 1870 were 271,288 bushels of Indian corn, 26,103 of sweet potatoes, and 13,643 bales of cotton. There were 703 horses, 1,933 mules and asses, 1,759 milch cows, 3,963 other cattle, 1,150 sheep, and 8,270 swine. Capital, Lumpkin. **II.** A N. W. county of Tennessee, bordering on Kentucky, intersected by the Cumberland river and bounded W. by the Tennessee; area, about 425 sq. m.; pop. in 1870, 12,019, of whom 2,700 were colored. The surface is undulating and the soil very fertile. Valuable iron ore abounds. The Louisville, Nashville, and Great Southern railroad passes through it. The chief productions in 1870 were 31,380 bushels of wheat, 428,311 of Indian corn, 26,623 of oats, 17,635 of Irish and 18,746 of sweet potatoes, 1,809 bales of cotton, 1,191,620 lbs. of tobacco, 16,135 of wool, and 10,335 gallons of sorghum molasses. There were 1,579 horses, 2,158 milch cows, 3,575 other cattle, 8,939 sheep, and 15,652 swine; 3 manufactories of pig iron, and 1 of blooms. Capital, Dover.

**STEWART, Alexander Turney,** an American merchant, born near Belfast, Ireland, Oct. 27, 1802, died in New York, April 10, 1876. He studied at Trinity college, Dublin, but did not take a degree, emigrated to New York in 1823, and engaged in teaching. In 1825 he began, at No. 283 Broadway, a dry-goods business which gradually expanded into one of the largest mercantile concerns in the world. He sent a ship load of provisions to Ireland during the famine of 1846, and made similar gifts to the sufferers by the Franco-German war and by the Chicago fire in 1871. In 1867 he was chairman of the honorary commission sent by the United States government to the Paris exposition. In March, 1869, President Grant appointed him secretary of the treasury, but his confirmation was prevented by the law which excludes from that office all who are interested in the importation of merchandise. Mr. Stewart left nearly completed a building on 4th avenue and 32d street, New York, costing more than $1,000,000, which was understood to be intended as a home for working girls, but which was finally made a general hotel; and he was also building at Hempstead Plains, Long Island, on a tract of 10,000 acres, a town known as Garden City.

**STEWART, Balfour,** a British physicist, born in Edinburgh, Nov. 1, 1828. He studied in the universities of St. Andrews and Edinburgh, and in 1852 engaged in business in Melbourne, Australia; but in 1854 he retired to Richmond, near Melbourne, and devoted himself to science. In 1855 he returned, and was assistant for six months to John Welch, superintendent of the Kew observatory, and afterward for three years to Prof. Forbes in Edinburgh, lecturing on mechanics and assisting in experiments. In 1859 he was appointed superintendent of the Kew observatory, and in 1861 examiner in the universities of London and Edinburgh. In 1868 he received the Rumford medal from the royal society. In 1870 he was appointed professor of natural philosophy in Owens college, Manchester, still retaining the directorship of the Kew observatory. Besides several papers in the "Transactions" of the royal society, he has published

"Elementary Lessons in Physics" (London, 1870); "Elementary Treatise on Heat" (1871); "Physics Primer" (1872); and "The Conservation of Energy" (1873).

**STEWART, Charles**, an American naval officer, born in Philadelphia, July 28, 1778, died in Bordentown, N. J., Nov. 7, 1869. He entered the merchant service at the age of 13 as cabin boy, and rose to the command of an Indiaman. In March, 1798, he entered the navy as lieutenant in the frigate United States, employed in the West Indies against French privateers. In July, 1800, he was appointed to the command of the schooner Experiment, of 12 guns. On Sept. 1 he captured, after an action of 10 minutes, the French schooner Deux Amis, of 8 guns; and soon after, near the island of Barbuda, the French schooner Diana, of 14 guns. He also recaptured several American vessels which had been taken by French privateers. As commander of the brig Siren he participated in the naval operations of 1804 against Tripoli, and aided in the destruction of the frigate Philadelphia. He became captain in 1806. In the summer of 1813 he took command of the Constitution, and in December sailed from Boston upon a cruise to the coasts of Guiana and the Windward islands, which resulted in the capture of the British schooner of war Pictou, of 14 guns, a letter of marque under her convoy, and several merchant vessels. About the middle of December, 1814, he sailed in the same ship upon a second cruise, and on Feb. 20, 1815, captured, after an action of 40 minutes fought at night, H. B. M. ship Cyane, mounting 34 guns, with 185 men, and the sloop of war Levant, of 21 guns and 156 men. The Constitution mounted 52 guns with 470 men. Her loss was 3 killed and 12 wounded, while the total loss of the British ships has been stated at 41. The Levant was recaptured by a British squadron. From 1816 to 1820 Com. Stewart commanded a squadron in the Mediterranean, and from 1821 to 1823 in the Pacific. He afterward served on the board of navy commissioners, and as commander of the home squadron and the naval station at Philadelphia. In 1857 he was placed on the retired list, but resumed service in 1859 as commander of the Philadelphia navy yard, under a new commission as senior flag officer; and on July 16, 1862, he was made a rear admiral on the retired list.

**STEWART, Dugald**, a Scottish metaphysician, born in Edinburgh, Nov. 22, 1753, died there, June 11, 1828. His father was the Rev. Dr. Matthew Stewart (1717–'85), professor of mathematics in the university of Edinburgh, and author of several mathematical works. He was educated at the high school and university of his native city, heard the lectures of Reid at Glasgow during one term (1771–'2), was recalled to Edinburgh to act as his father's substitute in the charge of the mathematical classes, and was formally elected conjoint professor in 1775. For several years he was prominent in the weekly debates of the speculative society, before which he also read essays on philosophical subjects. He was elected professor of moral philosophy in 1785, and lectured in this department during the next 24 years. His aim was always moral and practical more than speculative, to portray ideal perfection and advance the harmonious culture of all the faculties, intellectual, moral, and sensitive, rather than to teach definite solutions of intellectual problems; and his lectures therefore proceeded from psychology to theories of character and manners, life and literature, taste and the arts, politics and natural theology. The prominence which he assigned to the last subject, as the highest branch of metaphysics, was designed, as he explained, to resist the prevalent skeptical tendencies of the era of the French revolution. From the beginning he gave lectures on the theory of government as a part of the course on moral philosophy, and in 1800 he first delivered a special course on the new science of political economy. He published the first volume of "Elements of the Philosophy of the Human Mind" in 1792. In the following year he published his "Outlines of Moral Philosophy," and read before the royal society an account of the life and writings of Adam Smith, which was printed in the "Transactions," and was followed by his biographies of Dr. Robertson (1796) and Dr. Reid (1802). Nothing else appeared from his pen till 1810, though in this interval he prepared the matter of all his other writings, with a single exception. In 1806 the sinecure office of gazette writer of Scotland was created for him. He accompanied in that year Lord Lauderdale on his mission to Paris. In 1810 he retired, on account of failing health, from active duty as a professor, and published his "Philosophical Essays." He had in the mean time removed to Kinneil house, on the shore of the frith of Forth, 20 m. from Edinburgh, where he passed the remainder of his life. His later publications are: "Elements of the Philosophy of the Human Mind," vol. ii. (1814), and vol. iii. (1827); a preliminary dissertation to the supplement of the "Encyclopædia Britannica," entitled "A General View of the Progress of Metaphysical, Ethical, and Political Science since the Revival of Letters" (part i., 1815; part ii., 1821); and "The Philosophy of the Active and Moral Powers" (1828), which was completed only a few weeks before his death. In 1822 paralysis deprived him of the power of speech and of the use of his right hand, but by the aid of his daughter as an amanuensis he continued his studies until disabled by a fresh paralytic shock, which soon terminated fatally.—His collected works were edited by Sir William Hamilton (10 vols. 8vo, Edinburgh, 1854–'8; supplement, 1860). His lectures on political economy were first published in this edition. The 10th volume contains a memoir by John Veitch, with selections from his correspondence.

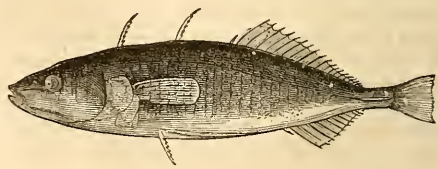
**STEWART, John,** an English traveller, born in London about 1740, died there in 1822. He went to Madras in 1763, in the civil service of the East India company, but at the end of two years resigned his office and began a series of pedestrian tours through Hindostan, Persia, Nubia, and Abyssinia, in the course of which he was at different times in the service of the nawaub of Arcot and of Hyder Ali. He next walked to Europe by the way of the Arabian desert; and having perambulated every part of Great Britain, he crossed the Atlantic and visited on foot many parts of the United States. He was commonly called "walking Stewart." His writings were printed in three volumes in 1810, mainly for private distribution. An account of his life and adventures was published after his death (London, 1822).

**STEWART, Robert Henry,** marquis of Londonderry. See CASTLEREAGH.

**STEWART ISLAND.** See NEW ZEALAND.

**STEYER, Steier,** or **Steyr,** a town of Upper Austria, between the Steyer and the Enns, at their junction, 19 m. S. E. of Linz; pop. in 1870, 13,392. It is united with its suburbs Ennsdorf and Steyerdorf by two bridges. There are extensive manufactures of hardware and cutlery in the town and surrounding villages. It was once the capital of a county, and till 1192 belonged to Styria, which from it derived its name (Ger. *Steyermark*).

**STICKLEBACK,** the popular name of the acanthopterous fishes of the mailed-cheeked family or *sclerogenidæ*, and genus *gasterosteus* (Linn.). They are also called banstickles, and are the *épinoches* of the French. Most of the species are found in fresh water, and are from 2 to 3 in. long; the sides are more or less protected by bony plates, the other parts being without scales; very small and crowded teeth on the jaws, none on the palate; branchiostegal rays three; tail keeled on both sides; ventrals abdominal, reduced to a strong spine, used as a weapon, and one or two soft rays; free spines, from 3 to 15 in front of the dorsal, which is supported by soft rays; bones of the pelvis large, forming an abdominal sternum. They feed on aquatic insects and worms, and the fry of fish; their pugnacity exceeds that of any other fish, and their voracity and fearlessness make it easy to capture them by the simplest means; they are very active, and sometimes spring entirely out of water. They breed in summer, in nests built by the males, which at this season have the throat carmine red and the eyes brilliant bluish green, the other parts above being ashy green and the abdomen silvery and translucent. The nest is made of delicate vegetable fibres, matted into an irregular circular mass cemented by mucus from the body, an inch or more in diameter, attached to water plants, with one or two openings near the centre; when the nest is prepared the female is enticed or driven in, and there deposits her eggs, which are fecundated by the male; the latter remains constantly on guard, swimming in the neighborhood, driving away intruders with great ferocity, frequently putting in his head to see if all is right, and fanning the water with the pectorals and caudal to secure free circulation and ventilation for the eggs; he is frequently seen shaking up the eggs, and carrying away impurities in the mouth. The young are hatched in two or three weeks, and grow very slowly; any of the small fry getting outside of the nest are instantly seized in the mouth of the parent and put back. There are about 40 young to a nest.—The common European species (*G. aculeatus*, Linn.; since separated into three by Cuvier) has three spines in front of the dorsal, and is found in almost every pool and rivulet in Great Britain. The *G. spinachia* (Linn.) has 14 or 15 free spinous rays on the back, and has an elongated head and body; it is a marine species, found in the northern seas of Europe. The best known of the many species in the United States are the two-spined stickleback (*G. biaculeatus*, Mitch.), which is found from Labrador to New York, 2 in. long, olive-green above, yellowish



Two-spined Stickleback (Gasterosteus biaculeatus).

green on sides, with two distant spines on the back and a third near the dorsal; and the four-spined stickleback (*G. quadracus*, Mitch.), of the Massachusetts and New York coasts. Other species have eight to ten spines, and the males in all assume the red tint in the breeding season, both in salt and fresh water.

**STICKNEY, Sarah.** See ELLIS, WILLIAM.

**STIEGLITZ. I. Christian Ludwig,** a German author, born in Leipsic, Dec. 12, 1756, died there, July 17, 1836. He was an architect, held important local offices, and published poetical and other works, but is chiefly known by his *Encyklopädie der Baukunst der Alten* (5 vols., Leipsic, 1792–'8) and *Geschichte der Baukunst vom frühesten Alterthum bis in die neuern Zeiten* (Nuremberg, 1827; 2d ed., 1836). **II. Heinrich,** a German poet, nephew of the preceding, born in Arolsen, Feb. 22, 1803, died in Venice, Aug. 24, 1849. He was librarian and teacher at Berlin from 1828 to 1833, when to cure his melancholy he started on a journey with his wife. The latter in 1834 killed herself in the hope that the sudden shock might restore his mental vigor. Her correspondence and diary were edited by Mundt: *Charlotte Stieglitz, ein Denkmal* (1835). Her husband subsequently led a wandering life. His works include *Bilder des Orients* (4 vols., Leipsic, 1831–'3), *Stimmen der Zeit in Liedern* (1832), and his posthumous *Selbstbiographie* and *Erinnerungen an Charlotte* (1865).

**STIEGLITZ, Ludwig von,** a Russian banker, born in Arolsen, Germany, of Jewish parents, in 1778, died in St. Petersburg, March 18, 1843. He was a brother of the medical writer Johann Stieglitz, and in early life went to St. Petersburg. He was poor, but gradually became rich and influential, and at his death left a colossal fortune. He was made a baron in 1825. His brothers Nikolaus and Bernhard also became rich, and one of the latter's sons was made councillor of the ministry of the interior. The son of Ludwig, the baron Alexander, continued the father's business till 1858, when he assumed the direction of the new government bank, retiring in 1866.

**STIGMARIA.** See Coal Plants.

**STILES, Ezra,** an American clergyman, born at North Haven, Conn., Dec. 15, 1727, died in New Haven, May 12, 1795. He graduated at Yale college in 1746, and was a tutor there from 1749 to 1755. He studied theology, and began preaching in June, 1749. He afterward studied law, was admitted to the bar in 1753, and practised at New Haven. In 1755 he became pastor of the second church in Newport, R. I., where, in addition to his professional duties, he engaged in oriental, linguistic, literary, and scientific investigations. His congregation at Newport being broken up by the British occupation of the place in May, 1777, he removed to Portsmouth, N. H., to become pastor of the North church. In September of the same year he was elected president of Yale college, and shortly after professor of ecclesiastical history, and from 1780 was also professor of divinity. He published an "Account of the Settlement of Bristol" (1785), and "History of three of the Judges of Charles I." (1795); and he left an unfinished church history of New England, besides more than 40 volumes of manuscripts. His life has been written by James L. Kingsley, in Sparks's "American Biography," 2d series, vol. vi.

**STILICHO, Flavius,** a Roman general, beheaded Aug. 23, A. D. 408. He was the son of a Vandal officer of the cavalry under the emperor Valens. For his services as an envoy to Persia in 384 Theodosius gave him the hand of Serena, his niece and adopted daughter. Stilicho shortly became master general of the army in the western parts of the empire, and gained several victories over the barbarians. Jealousy between him and Rufinus, whom Theodosius made governor of the East, soon ripened into intense hatred. In 394 Stilicho became governor of the West, as guardian of Honorius, whom Theodosius had proclaimed Augustus. Theodosius died in 395, leaving to Honorius the empire of the West, and to Arcadius that of the East. After crossing the Alps and establishing a firm peace on the border, Stilicho turned toward the East, ostensibly against Alaric, but really to break the power of Rufinus. He was stopped near Thessalonica by a message from the Byzantine court, but engaged Gainas, the leader of the Gothic allies of Arcadius, to put Rufinus to death, which he accomplished, Nov. 27, 395. In 396 Stilicho, without being asked for aid by Arcadius, sailed from Italy against the barbarians, who were ravaging northern Greece and the Peloponnesus; but Alaric escaped into Epirus, of which he took possession. Arcadius ordered Stilicho to leave his territory, and made Alaric master general of the province of Illyricum. In 398 a marriage was celebrated between Stilicho's daughter Maria and Honorius. In 402 Alaric invaded Italy, and Stilicho, collecting his scattered troops from Rhætia, Gaul, and Germany, defeated him at Pollentia (403), and again soon after under the walls of Verona. Alaric then departed, and Stilicho in 404 received the honor of a triumph in Rome. He now formed an alliance with his late enemy against the emperor of the East, promising to pay him a large annual subsidy. In 405 Italy was invaded by Radagaisus, at the head of a multitude of Vandals, Suevi, Burgundians, Alans, and Goths. While they besieged Florence, Stilicho cut off their communications and forced them to capitulate (406). Radagaisus was put to death, and his men were sold as slaves; but the other portion of this horde, which had not entered Italy, ravaged Gaul, from which Stilicho had been obliged to withdraw the garrisons. A large party were indignant at Stilicho's supposed partiality for the barbarians, and especially at the decline of the authority of Rome over Britain, Gaul, and Spain. His power at court was also secretly undermined by the eunuch Olympius, whom he himself had introduced into the imperial palace. The latter represented to Honorius that he was without authority in his own kingdom, and that his death was meditated by Stilicho, who designed placing the imperial crown upon the head of his son Eucherius. While Honorius was at Pavia in 408, through the agency of Olympius, the friends of Stilicho, some of the most illustrious officers of the empire, were murdered. Stilicho was in the camp of the barbarian allies at Bologna, and his friends demanded to be led against the murderers. He hesitated, and his friends left him to his fate. An attempt to assassinate him was made by Sarus, a Goth, but Stilicho escaped and took refuge in a church in Ravenna. From this sanctuary he was led out by Count Heraclian and instantly slain.

**STILLÉ, Alfred,** an American physician, born in Philadelphia, Oct. 30, 1813. He graduated at the university of Pennsylvania in 1832, and was resident physician of the Philadelphia hospital in 1836, and of the Pennsylvania hospital in 1839–'41, having employed the interval in attending medical lectures in Paris and other capitals of Europe. He became lecturer on pathology and practice of medicine to the Philadelphia association for medical instruction in 1844, physician to St. Joseph's hospital in 1849, and afterward professor of the theory and practice of medicine in the Pennsylvania

medical college, and since June, 1864, in the university of Pennsylvania. He has published "Medical Instruction in the United States" (Philadelphia, 1845); "Elements of General Pathology" (1848); "Report on Medical Literature" (1850); "The Unity of Medicine" (1856); "Humboldt's Life and Character" (1859); and "Therapeutics and Materia Medica" (2 vols. 8vo, 1860; revised and enlarged, 1864; 4th ed., 1874).—His brother Moreton (born Oct. 27, 1822, died Aug. 20, 1855), resident physician of the Pennsylvania hospital in 1848–'9, and afterward lecturer to the Philadelphia association for medical instruction, published with Francis Wharton a "Treatise on Medical Jurisprudence" (Philadelphia, 1855; 2d ed., with medical part revised and enlarged by Dr. Alfred Stillé, 1860).

**STILLINGFLEET, Edward,** an English bishop, born in Cranborne, Dorset, April 17, 1635, died in London, March 27, 1699. He was educated at Cambridge, at the age of 18 obtained a fellowship, and in 1657 was presented to the rectory of Sutton. Subsequently he became chaplain in ordinary to Charles II. and dean of St. Paul's, and in 1689 bishop of Worcester. He published "Irenicum, or the Divine Right of particular Forms of Church Government Examined" (1659), manifesting much more toleration than his later works; "A Rational Account of the Grounds of Protestant Religion" (fol., 1664); "Discourse concerning the Idolatry practised in the Church of Rome" (1671); a sermon against the nonconformists entitled "The Mischief of Separation," to the criticisms upon which he replied in a volume entitled "The Unreasonableness of Separation" (4to, 1681); and tracts against Roman Catholics and Socinians. He is best known by his "Origines Sacræ, or Rational Account of the Grounds of Natural and Revealed Religion" (4to, 1662), and his "Origines Britannicæ, or the Antiquities of the British Churches" (1685). When James II. revived the court of ecclesiastical commission, Stillingfleet refused to be a member of it, and after the revolution of 1688 he published a discourse concerning the illegality of the commission. In the latter part of his life he engaged in a sharp controversy with Locke on the latter's definition of substance and theory of ideas in general. His works were printed in 1710 in 6 vols. fol., to which was added in 1735 a volume of his miscellaneous writings.

**STILLWATER,** N. Y. See Saratoga, Battle of.

**STILLWATER,** a city and the county seat of Washington co., Minnesota, on the W. bank of the St. Croix river, 25 m. N. of its junction with the Mississippi, and 16 m. E. N. E. of St. Paul, with which it is connected by two lines of railroad; pop. in 1870, 4,124; in 1875, 5,750. It is the centre of the lumber trade of the St. Croix valley, and contains seven saw mills, a flouring mill, two planing mills, an extensive cooperage and cabinet factory, two national banks, two large public school buildings, the state prison, a public library, three weekly newspapers, and nine churches.

**STILT,** a wading bird of the avocet family, and genus *himantopus* (Briss.). The bill is long, straight, slender, and pointed, with a groove on each side to the middle; wings long and pointed, first quill much the longest; tail short and nearly even; legs very thin and long, with scaled tarsi; toes moderate, joined at the base, with a wide membrane between the outer and middle toes; hind toe wanting; claws small and sharp; neck long. Half a dozen species are found in various parts of the world. The black-necked stilt (*H. nigricollis*, Vieill.) is about 14 in. long, black above, with forehead, lower parts, rump, and tail white; bill black, and legs red. It is found as far N. as the middle states in spring, frequenting salt marshes in small flocks, and going S. beyond the limits of the United States in autumn; the nests are built in company, at first upon the

Black-necked Stilt (Himantopus nigricollis).

ground, from which they are gradually raised by successive additions; the eggs are usually four, of a pale yellowish clay color, with large irregular blotches and lines of brownish black; the flight is rapid and regular, the legs extending behind; the flesh is indifferent eating. The white stilt (*H. melanopterus*, Meyer) is of about the same size, and white, with the back and wings shining greenish black, and legs red; it prefers the edges of fresh-water streams, and is found in S. E. Europe, Asia, and Africa; the bill is 3 in. and tarsus 4 in.

**STIMPSON, William,** an American naturalist, born in Roxbury, Mass., Feb. 14, 1832, died at Ilchester Mills, Howard co., Md., May 26, 1872. He studied under Agassiz, and in 1849 engaged in dredging off the coast of New England. In 1852 he accompanied Agassiz to Norfolk, Va., to investigate the marine fauna of that region. In 1852–'6 he was naturalist to the North Pacific exploring expedition, and in December, 1864, became curator

of the Chicago academy of sciences, and afterward secretary and director of the museum. The great fire of October, 1871, destroyed his collections and manuscripts, embodying the results of 20 years of scientific labor, including his works on the shells of the E. coast, and on the crustacea of North America, with 500 drawings and 200 illustrations already engraved. He passed the winter of 1871-'2 off the Florida coast, till a hæmorrhage of the lungs ended his activity. His works include "A Revision of the Synonymy of the Testaceous Mollusks of New England" (Boston, 1851); "Synopsis of the Marine Invertebrata of Grand Menan," &c. (in vol. vi. of "Smithsonian Contributions to Knowledge," Washington, 1854); "Crustacea and Echinodermata of the Pacific Shores of North America" (Boston, 1857); *Prodromus Descriptionis Animalium Evertebratorum quæ in Expeditione ad Oceanum Pacificum Septentrionalem*, &c. (8 parts, Philadelphia, 1857-'60); "Notes on North American Crustacea" (New York, 1859); and "Researches upon the Hydrobiinæ and Allied Forms" (1865).

**STIRLING,** a town of Scotland, capital of Stirlingshire, on the river Forth, 31 m. W. N. W. of Edinburgh; pop. in 1871, 14,279. It is on a height at the head of the navigation of the river, which is crossed by two bridges and a railway. Many of the public buildings are very ancient. The castle, which stands upon a rocky height 220 ft. above the plain, holds a prominent place in the history of Scotland, and is connected with most of the important events that occurred in that kingdom before it was annexed to England. The ancient royal palace is still standing, and there is also a palace begun by James V. and finished by his daughter Mary. There are several ancient churches and some modern ones, and numerous schools. The town house is very ancient, and the old residence of the earl of Mar is very curious. Stirling has manufactories of woollens, leather, ropes, &c. The river is shallow, but a considerable trade is carried on. The Scottish Central railway passes the town, and three other railways terminate here.

**STIRLING, Earl of.** See ALEXANDER, WILLIAM.

**STIRLING, James Hutchinson.** See p. 898.

**STIRLING, Sir William** (MAXWELL), a Scottish author, born near Glasgow in 1818, died Jan. 15, 1878. He graduated at Cambridge in 1839, and resided several years in Spain. He published "Annals of the Artists of Spain" (3 vols. 8vo, 1848), "The Cloister Life of the Emperor Charles the Fifth" (1852), and "Velasquez and his Works" (12mo, 1855), and edited the marquis de Villars's *Mémoires de la cour d'Espagne sous le règne de Charles II.* (4to, 1862). From 1852 to 1865 he was a member of parliament for Perthshire. In 1866 he succeeded to the baronetcy and estates of his uncle, Sir John Maxwell, and assumed the surname of Maxwell. He was elected rector of the university of St. Andrews in 1863, and of that of Edinburgh in 1872.

**STIRLINGSHIRE,** a central county of Scotland, bordering on the counties of Perth, Clackmannan, Linlithgow, Lanark, and Dumbarton; area, 466 sq. m.; pop. in 1871, 98,218. The chief rivers are the Forth, Avon, Kelvin, Endrick, and Carron. Loch Coulter, Loch Elrigg, and half of Loch Lomond are in the county. Ben Lomond, in the N. W. part, rises 3,192 ft. above the sea. Coal and iron are mined; wool and cotton are manufactured; and there are immense iron works at Carron. The principal towns are Stirling, Falkirk, Alva, Bannockburn, and Denny.

**STOAT.** See ERMINE.

**STOBÆUS, Joannes,** a Greek compiler, probably born at Stobi in Macedonia, lived probably in the 5th century A. D. He made extracts from more than 500 Greek authors, many of whom are not otherwise known to us. The work was early divided into two portions, the one called "Anthology" (*Florilegium*) or *Sermones*, the other "Physical, Dialectical, and Ethical Extracts" (*Eclogæ Physicæ, Dialecticæ et Ethicæ*). The best edition of both portions is that of Meineke (6 vols., Leipsic, 1855-'62).

**STOCK.** See GILLIFLOWER.

**STOCKBRIDGE,** a town of Berkshire co., Massachusetts, on the Housatonic river and railroad, 115 m. in direct line W. of Boston, and 12 m. S. by W. of Pittsfield; pop. in 1870, 2,003; in 1875, 2,089. The surface of the town is varied; in the south is Monument mountain, separating it from Great Barrington, in the west West Stockbridge mountain, in the southeast the Beartown mountains, and in the northwest Rattlesnake mountain. Between these are valleys of great beauty. The Housatonic and its affluents drain the town. The Stockbridge or Housatonic Indians, among whom John Sergeant and Jonathan Edwards labored as missionaries, formerly had their home here, but removed westward in 1788. The villages of Glendale and Curtisville have some manufactures. The village of Stockbridge has a hotel, a bank, an insurance office, an incorporated academy, several private schools, a library, and three churches (Congregational, Episcopal, and Roman Catholic).

**STOCK EXCHANGE,** a place where stocks are bought and sold. In England the term stocks is confined to government stocks, annuities, &c., and the term shares is used for the capital or stock of railroad, banking, and other companies; but in the United States bonds representing national, state, county, and city debts, and the shares of railroads, banks, mining, manufacturing, telegraph, and insurance companies, are all called stocks. In France the word *rentes* has the same limitation as stocks in England. Dealing in stocks, bonds, and annuities is the business of the stock exchange, and the dealers in them are known as stock brokers and stock jobbers. In New York the traffic in stocks is of two kinds, the regular sales at the first and second boards,

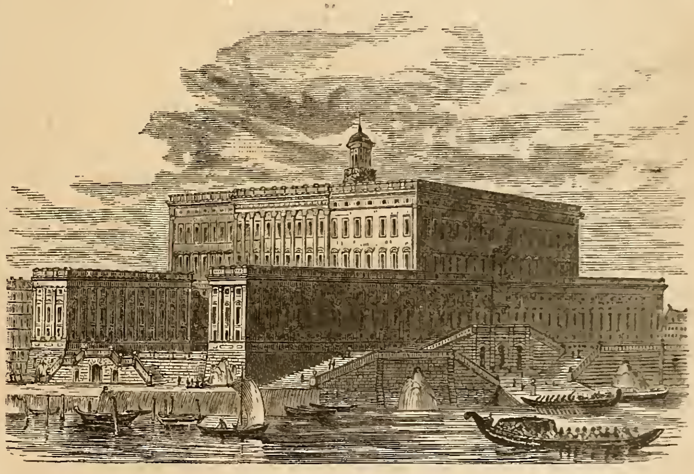
and the operations of the street. The first are legitimate, and the sales are presumed to be *bona fide;* the second are generally speculative, and are often mere gambling or betting by men without capital. The board of brokers in New York is composed of more than 1,000 regular members, who at their two daily sessions, either on their own account or as brokers for others, purchase or sell the various stocks which are called in order. The president, secretary, treasurer, and governing committee of 40 members are the executive of the exchange, and can admit, suspend, expel, and readmit members. Next in importance is the sub-committee of arbitration, which decides all disputes arising from transactions between members. When a member fails to deliver or pay for stocks as agreed, his name is struck from the list; but he may be reinstated upon effecting a settlement with his creditors. The New York stock exchange is the wealthiest organization of the kind in the world. The par value of annual sales made at the boards and "over the counter" is estimated at more than $22,000,000,000; but this enormous sum covers all sorts of speculative transactions, including those where no actual transfer of stocks occurs, and "differences" only are paid or adjusted, these operations forming in fact the bulk of the business in Wall street. The rules of the exchange are very strict, and cover a rigid scrutiny of all securities, a systematization of the brokerage business of member with member, a surveillance over members in respect of their fidelity to contracts, and a stringent examination of the character and responsibility of candidates for membership. An applicant for membership must be 21 years old, a banker, broker, or stock dealer in New York for one year, or a clerk to a member for two years, or a member in good standing of the Philadelphia, Baltimore, or Boston board. The initiation fee of a member admitted by election has recently been fixed at $10,000, and of one admitted by transfer at $500. During business hours the board is in constant communication with the financial centres of Europe, and the brokers pay $1,000,000 a year for telegrams from London alone.—The stock exchange has its own peculiar terms, not generally understood by outsiders. Among those in most frequent use are "long" and "short," expressing individual excess or deficiency in the holding of a specified stock for speculative purposes; and "bull" and "bear," designating those respectively who find their interest in operating for a rise or fall in the price of stocks, or who, foreseeing either a rise or fall, take measures to protect themselves or make a profit on the "turn of the market." The bull endeavors to appreciate or "toss up," and the bear to depreciate or "pull down" the price. The phrase "buyer's option," added to the memorandum of a sale of stocks, implies that the purchaser who buys at 30 or 60 days can call for the delivery of the stocks at any time within the period by giving one day's notice and paying interest at 6 per cent. up to the time he calls. Such purchases are usually made at a little above the cash price. "Seller's option" is a little below the cash price, and the seller has the right to deliver on any day within the limited time, by giving one day's notice, receiving interest up to the time of delivery. A "corner" is an operation by one or several brokers, who form a clique to compel others to pay a heavy difference on the price of stock. Sometimes the clique purchase gradually a large amount of stock on time, buyer's option; they next sell nearly the same amount on time, seller's option, so as to secure an eventual market for their stock; then buy for cash, thus raising the price, and make a sudden call for the stock they have purchased on buyer's option, which, if they have calculated correctly, compels the parties from whom they have purchased to buy of them at a high price in order to deliver at a low one. "A point," the first element of successful speculation, is trustworthy private information concerning a certain stock, such as whether a bull movement is organizing, or an extra dividend is to be declared, or new stock is to be issued, or any other cause is likely to affect the price. A "lame duck" is a broker who is unable to respond with the shares or money when contracts mature. A "spread eagle" is the operation of a broker who sells a large quantity of stock on time, say 60 days, buyer's option, and buys the same quantity at a lower price, on the same time, seller's option. If both contracts run their full time, he makes his difference; but if the buyer or seller calls for a settlement before the time, he may be seriously embarrassed. The "street" or the "curbstone brokers" are not governed by as strict rules, and their operations are mostly speculative. "Put," "call," "ballooning," "saddling," "unloading," and more than 40 other terms make up the dialect of the exchange.—In the Paris *bourse* there are 60 *agents de change*, appointed by the government. Each must deposit 125,000 fr. in the national treasury as a guaranty of upright conduct, and also 100,000 fr. with the syndicate of the bourse as a cautionary fund applicable to losses sustained by the customer through the broker's fault. A broker's seat is worth from 1,500,000 to 2,000,000 fr., and cannot be sold without the consent of the governing committee. There are 60 *courtiers de commerce* and 8 *courtiers d'assurance*, who transact much of their business at the bourse. The *haussiers* and *baissiers* correspond to the American bulls and bears, and the *coulisse* to street or curbstone operators. Cash sales are infrequent, and the greater part of the business is "privilege," technically *marché à prime*, the buyer deciding on the 15th and 30th of the month whether he will take the stock or not, but in either case having to pay the premium. The time transactions are usually "the end of the current month,"

or the end of the next month. The 4th of each month is settling day. The *parquet* is in session from 1 to 3 P. M. every day; the *coulisse* is in session through the day, and it includes a large number of female jobbers and speculators. The London stock exchange numbers nearly 2,000 regular members, who must be reëlected annually. Each member pays £10 yearly, and three members give security to the amount of £300 each for a new member.—The excitement at the hour of "high 'change," in London, Paris, or New York, is often such as beggars description; several hundred men are shouting, calling out what they have to sell or what they wish to buy, at the top of their voices, all together, and leaping and gesticulating, almost as if insane; in speculative periods, immense sums are made or lost in a few minutes. The stock exchanges of Amsterdam, Berlin, Frankfort, Madrid, and Vienna are among those most noted in Europe.

**STOCK FISH.** See Cod.

**STÖCKHARDT, Julius Adolf,** a German chemist, born at Röhrsdorf, Saxony, Jan. 4, 1809. After serving in a pharmacy, he taught natural sciences at Dresden in 1838–'9, afterward at Chemnitz till 1847, and in 1848 was called to the new chair of agricultural chemistry in the academy of Tharand. In 1844 he began a course of lectures before the Chemnitz agricultural society, which led to the establishment of the system of agricultural experimental stations. From 1846 to 1849 he edited *Das polytechnische Centralblatt*, and from 1850 to 1855 (with Schober), *Die Zeitschrift für deutsche Landwirthe;* and in 1855 he established at Berlin *Der chemische Ackersmann*, in which are published his familiar lectures before farmers' clubs and societies, which he calls "field sermons." It is said that the yield of grain in Saxony has been doubled chiefly through his efforts. His principal works are: *Untersuchung der zwickauer Steinkohlen* (1840); *Ueber Erkennung und Anwendung der Giftfarbe* (1844); *Schule der Chemie* (1846; 17th ed., 1873; English translation by G. H. Pence, M. D., "The Principles of Chemistry illustrated by Simple Experiments," Cambridge, Mass., 1850; also by A. Henfrey, London, 1855); *Guanobüchlein* (1851); and *Chemische Feldpredigten* (1851; English translation by J. E. Teschemacher, "Chemical Field Lectures for Agriculturists," Cambridge, Mass., 1853).

**STOCKHOLM,** a city and the capital of Sweden, in lat. 59° 20′ N., lon. 18° 3′ E., 330 m. N. E. of Copenhagen; pop. in 1874, 147,249. It is partly built on islands and intersected by many canals, surrounded on the land side by rocks, forests, and hills, and on the water side by Lake Mælar and the Salt Sjö (Salt lake), an arm of the Baltic. This combination of land and water, together with the magnificent harbor and palace, and other remarkable sights, forms one of the most picturesque panoramas in the world. The city is well built, has several fine squares, and abounds in stately buildings. The royal palace, completed in 1754, consists of a huge quadrangle of solid granite; it is as remarkable for the fitting up of the royal apartments as for its grand and admirable proportions, and the chaste yet massive style of its Italian architecture. It is on the highest and most central of the three islands of the original town, distinctively called the city (*Stad*), and one of



Royal Palace, Stockholm.

the three main metropolitan divisions. These islands have been enlarged by embankments built on piles, whence the name of Stockholm, meaning an island on piles. The other two chief divisions are the northern suburb (*Norrmalm*), the fashionable quarter, and the southern suburb (*Södermalm*), that of the working classes; the former is connected with the city by a fine granite bridge, and the latter by several drawbridges, and there is a new line of railway, with remarkable viaducts and tunnels. The principal government offices and mercantile houses are adjacent to the palace and the quay, and the most elegant stores are in Norrmalm. The building next in beauty to the royal palace is the new national museum, at the S. end of the formerly separate island of Blasiiholm, which is now united to Norrmalm. Its front faces the terrace garden of the royal palace, overlooking the harbor; it is 260 ft. long by 170 ft. broad, and 90 ft. high,

and has three stories filled with interesting collections, soon to include the picture gallery of the palace. A new building has also been provided for the royal or national library of about 70,000 volumes and 4,000 unique manuscripts, which occupied a space extending over nearly the whole S. E. wing of the palace. There are more than 25 places of worship, chiefly for Lutherans, but including several for other Protestants, one for Catholics, one for Swedenborgians, and a new and handsome synagogue. The interior of the church of St. Clara is exceptionally fine. The Swedish kings are crowned in the old St. Nicholas church. The most ancient church is that of Solna, with the tomb of Berzelius, and the most picturesque is the Riddarholm, originally a Franciscan convent and now used as a pantheon. In the latter are the armor of Charles IX., attributed to Benvenuto Cellini, the shrine of Gustavus Adolphus, and that of Charles XII. in the opposite Carolin chapel. Bernadotte is buried in the chapel of the present dynasty, adjoining the Gustavan. Other notable buildings are the governor's palace; the houses of parliament, including the Riddarhus, or house of the nobles and the diet; the royal mint; the exchange; the academy of sciences, with a library of 40,000 volumes, a cabinet of natural history, and a museum with rich zoölogical, mineralogical, and geological collections; the geological and technological institutes; the mining academy, recently removed hither from Fahlun; the new art union and exhibition buildings, with concert rooms; the royal theatre, where Gustavus III. was assassinated in 1792; and the houses in which Swedenborg and other eminent men were born. The most celebrated educational institution is the medical faculty, the principal one in Sweden, attended by a much larger number of students than that at the university of Upsal. A new free university is projected, and there are three gymnasia, various special schools, a military college, and a high school of artillery, the last near the city at Marieberg. No city has a greater variety of rural and waterside pleasure grounds. The most celebrated is the Djurgard or deer park, which occupies almost an entire island opposite the "city," since 1868 united to the metropolitan district. It is about 3 m. in circumference, and contains the Rosendal palace. The Haga park, a little beyond the observatory, opposite the new cemetery, is studded with islands, has water communication between its different parts and the city, and contains a royal palace. The adjacent park of Carlberg is another delightful summer resort. The park known as the Humlegard (hop garden), W. and N. W. of Norrmalm, has been greatly improved; it contains the new library building and large barracks. In Berzelius's park is a monument to Berzelius. Among the other numerous monuments in the city are those to Birger Jarl and to Swedish sovereigns. That of Charles XII. was erected in 1868, opposite the palace in the Kungsträdgard (king's garden) square. Few cities present greater natural beauties than Stockholm, and in the vicinity are many royal and private summer palaces and villas. The city is also the centre of Swedish industry and trade. It has about 300 manufacturing establishments, chiefly of sugar, tobacco, machinery, cast iron, leather, silk, soap, cloth, and porcelain. It is the principal Swedish port of entry. The imports in 1874 amounted to about $50,000,000, and the exports to $30,000,000; and the customs receipts reached nearly $6,000,000. The entries of British ships alone comprised 38 steamers and 161 sailing vessels. The total inward shipping in the foreign trade includes over 1,500 vessels, besides nearly 10,000 in the coasting trade, and about 60 local steamers. The exports to the United States in 1873-'4, chiefly iron, were valued at $1,063,997 in gold. The harbor accommodates the largest vessels, and is defended by a fortress.—The reputed founder of Stockholm was Birger Jarl, the father and guardian of Waldemar, elected king in 1250. A settlement had been in existence at the spot since the destruction of Sigtuna by Finnish pirates in 1187. It was a powerful stronghold against the devastations of the pirates in all the towns along Lake Mælar, and was frequently besieged. Stockholm became the residence of the Swedish monarchs soon after Birger's death, though Upsal continued long afterward to be the seat of government. With Lübeck and Hamburg reciprocity of free trade was established, and soon after with Riga. In 1501 the citadel was held against insurgents by Christina, queen of Denmark, whose husband, King John, ruled over the three united kingdoms of Scandinavia. King John had left his queen in command of a garrison of 1,000 men, whose number, after a siege of eight months, was reduced to about 80. She was compelled to capitulate, May 27, 1502. A still more heroic defence against the Danes under Christian II. was made by Christina Gyllenstjerna, the widow of the fallen regent Sten Sturé. After a terrible siege of four months, the place was surrendered, Sept. 7, 1520, with the solemn guarantee of the king to respect the rights of the inhabitants. A fearful massacre ensued, known as the "blood bath of Stockholm." Many treaties have been signed here in modern times; in 1855 that with the western powers guaranteeing the integrity of Swedish territories.

**STOCKING**, a close-fitting garment for the foot and leg, usually knit or woven. From paintings found at Pompeii, as also from notices in some of the Latin classics, it appears that stockings were known to the Romans in the latter days of the republic and under the empire; but they formed no part of the ordinary costume. *Fasciæ*, bandages wound round the leg from the ankle to the knee, were sometimes worn by persons in delicate health, or as a pro-

tection to the legs when walking through briers, as in hunting, on the march, &c. The art of knitting stockings is usually said to have originated in Scotland in the early part of the 16th century. In the times of Elizabeth it was an important industry in England, and the queen's government refused letters patent to William Lee, the inventor of the stocking frame (1589), on the ground that the machine-made goods would drive the home-made out of the markets and ruin the workpeople. Lee took his machine to France, and established a factory at Rouen, where he employed a number of his own countrymen. Political troubles soon drove him out of Rouen, and he died on the way to England. His brother introduced the manufacture into Nottinghamshire, which has ever since been famous for its production of stockings. Stocking frames were introduced into the United States in the 18th century at Philadelphia and Germantown, Pa., New York city, and several places in the middle and eastern states. The adaptation of the Lee machine to power was first accomplished by Timothy Bailey of Albany in 1831; and the first machine thus run was at Cohoes, N. Y., in 1832. The old Lee invention was a square frame, producing a straight strip, which was cut off in proper lengths, and seamed together to form the stocking. But a great improvement upon this, the origin of which is unknown, was the circular loom in which a continuous circular web is knit of any length, which is cut up and formed into the shape of a stocking. Several others have since been devised in the United States for manufacturing purposes, as also for family use.—The various knitting machines, which are too numerous to be mentioned in detail in this article, produce what is called the stocking stitch or chain work, consisting of loops formed in succession upon a single thread, each one locked by that which follows it. These machines may be distinguished by the different kinds of needles they employ, and also by the manner in which these are arranged: whether on a straight horizontal line, all pointing the same way, as in the common stocking loom, or around an open horizontal circle, all pointing toward the centre. The latter are known as the rotary round machines. Every needle is hooked at the end, so as to hold the thread laid across it that is to form the next loop, while the loop previously formed on the same needle slips back on the shank as the needle is pushed forward, and with its return runs over the hook and off the end. The contrivance by which this is effected distinguishes the several needles. In the straight frames the work is done first across the needles in turn in one direction and then back in the other, and so on; but in the rotary round machines the revolution carries the needles constantly round in the same direction, each one taking up the thread in turn, and so rapidly that the movements cannot be clearly perceived. The one class of machines produces a flat web, and the other a tubular one, each of which hangs from the needles and is drawn down as it lengthens by means of a weight. The number of stitches or loops which each machine can form in a minute varies with the gauge of the needles or the distance apart at which they are set. The machines constructed for family use, and worked by a treadle or crank like a sewing machine, make about half as many stitches as the factory machines. In the factory three or four machines are easily tended by one boy. Ribbed work is performed in the same machines by bringing in play a set of vertical needles, so arranged as to work in connection with the horizontal and produce the additional stitches required. As the needles are set to a particular gauge, they necessarily produce the same number of stitches to the inch; and the only variations practicable in the work are in using yarns or threads of different degrees of fineness, and in altering the tension so as to make the work closer or more open.—The shaping of the web to fit the foot is a matter of no little ingenuity. The flat web is either knit in long strips of sufficient width to make when turned over several stockings which are cut out from these; or the web is at once knit upon the machine in the shape required for making a stocking when the parts are properly folded over. In the latter the wider part, when turned over and fastened, forms the leg of the stocking. Two narrow strips at the base of this part, turned under and joined together, form the heel; while a central strip twice the length of the foot, being turned over at the toe, forms the top and bottom of the foot, and is neatly united to the heel and around its edges by knitting or seaming. In forming the foot to the cylindrical webs, a slit is made above the heel half across the web, which admits of the part designed for the foot being curved out at the instep. The loops along the edges of the cut are then taken up on hand needles, and the space for the heel is filled out by hand knitting. In the same manner the toe is completed; and thus the stocking is finished without a seam.—Notwithstanding the large number of machines employed in knitting, stockings are still largely produced by the old method of hand knitting, which admits of the use of a harder and firmer yarn than that adapted to the machines; and even where the machine work is produced in large mills employing steam power, the hand looms are also in extensive use, many of them in the houses of the operatives. In the factories the knitting machines are also made to produce many other articles of apparel, as undershirts, drawers, comforters, scarfs, opera hoods, talmas, nubias, gloves, mits, &c. The total production of this class of goods (hosiery) in the United States in 1870 amounted to $19,871,254; number of hands employed, 14,105. Nearly the whole amount was produced in the following states: New York, $5,528,742; Pennsylvania, $5,306,738; Massachusetts, $3,213,481; New Hampshire, $1,757,445; Connecticut,

$1,251,742; New Jersey, $568,900; Vermont, $551,129; and Rhode Island, $137,000.

**STOCKMAR, Christian Friedrich**, baron, a German physician, born in Coburg, Aug. 22, 1787, died there, July 9, 1863. He practised medicine at Coburg, and in 1814-'15 in the army. In 1816 he became physician to Prince Leopold, and soon afterward his private secretary, and was comptroller of his household till after his accession in 1831 to the Belgian throne. Subsequently Leopold sent him to London to assist the princess and future queen Victoria with his advice. In 1836 he arranged the marriage of Prince Ferdinand of Coburg with Queen Maria II. of Portugal, and in 1837 accompanied Prince Albert to Italy. He was the trusted friend of the Coburg princes and other high personages, especially of Queen Victoria and Prince Albert, to whom he made a long visit every year till 1857. In 1858 he aided in the negotiations for the marriage of the present crown prince of Prussia with the English princess royal. The latter designed the monument erected to him at Coburg. He received the title of baron from several sovereigns. —See *Denkwürdigkeiten aus den Papieren des Freiherrn Christian Friedrich von Stockmar*, by Ernst von Stockmar (Brunswick, 1872; English translation, edited by Max Müller, "Memoirs of Baron Stockmar," 2 vols., London, 1873).

**STOCKPORT**, a town of Cheshire, England, at the junction of the Mersey and the Thame, 5 m. S. E. of Manchester; pop. in 1871, 53,014. It stands upon a hill, and the houses rise above each other in irregular tiers. The Mersey is crossed by five bridges, and there are several suburbs, the most extensive of which are Heaton-Norris, Edgeley, and Portwood. The principal public buildings are the barracks, court house, union workhouse, and the building for the Sunday school, which is attended by nearly 4,000 children. A magnificent railway viaduct of 26 arches spans a portion of the town as well as the river Mersey. The former extensive manufacture of silk has been supplanted by that of cotton, for the spinning and weaving of which there are in the town and suburbs about 100 factories. There are also establishments for bleaching, dyeing, and printing cotton, brass and iron founderies, &c. Rich coal mines are worked in the vicinity.

**STOCKTON**, a city and the capital of San Joaquin co., California, on a level prairie at the head of Stockton slough, a wide and deep arm of the San Joaquin river extending E. from that stream for about 3 m., and on the Central Pacific railroad, 63 m. (direct) E. by N. of San Francisco; pop. in 1860, 3,679; in 1870, 10,066, of whom 4,102 were foreigners, including 1,076 Chinese; in 1875, estimated at 14,000. The Stockton and Copperopolis railroad extends to Milton, Calaveras co., 30 m., and from it branches the Stockton and Visalia railroad, extending to Oakdale, Stanislaus co., 34 m. from Stockton. The Visalia division of the Central Pacific railroad, branching from the main line 9 m. W. of the city, runs S. through the San Joaquin valley for nearly 200 m. A narrow-gauge railroad to Ione City, Amador co., about 40 m., will render available the immense coal deposits of that county. Stockton has a good harbor, and the river is navigable to this point from San Francisco at all seasons by vessels of from 150 to 250 tons. In the winter and spring steamers ascend nearly 200 m. above the city. The business blocks are principally of brick. The court house and city hall, near the centre of the city, is surrounded with choice shade trees and shrubbery, as are also many of the residences. Several of the churches are costly structures. The city is lighted with gas, and is supplied with water through pipes from three artesian wells. It has a volunteer fire department, and a horse railroad. The business of Stockton consists chiefly in furnishing supplies to the farmers of the San Joaquin valley and in the shipment of wheat, wool, and other produce. The shipments of wheat for the three years 1873-'5 averaged nearly 3,500,000 bushels, valued at about $3,000,000. The city contains four banking institutions, with an aggregate capital of $1,650,000, including a national gold bank and a savings and loan society. There are two manufactories of carriages, three of agricultural implements, two of sash, blinds, &c., one of paper, several of boots and shoes, saddlery and harness, furniture, tinware, &c., two flouring mills, two iron founderies, three tanneries, and three breweries. Considerable wine is also made here. Stockton is the seat of the state lunatic asylum. It has a high school and 33 other public schools of different grades, three newspapers, each having daily and weekly editions, and 12 churches, viz.: 2 Baptist, 1 Congregational, 1 Episcopal, 1 German Reformed, 1 Jewish, 3 Methodist, 2 Presbyterian, and 1 Roman Catholic. The city was laid out in 1849 and incorporated in 1850.

**STOCKTON. I. Richard**, a signer of the Declaration of Independence, born near Princeton, N. J., Oct. 1, 1730, died there, Feb. 28, 1781. He graduated at the college of New Jersey, at Newark, in 1748, was admitted to the bar in 1754, became a member of the executive council of New Jersey in 1768, and in 1774 a judge of the supreme court. In 1776 he was elected to congress, and served on the committee appointed to inspect the northern army. After his return to New Jersey he was captured by the British, confined in the common prison at New York, and treated with such severity as ultimately to cause his death. **II. Robert Field**, an American naval officer, grandson of the preceding, born in Princeton, N. J., in 1796, died there, Oct. 7, 1866. He entered the navy in 1810, became a lieutenant in 1814, and in 1821 went to Africa in command of the Erie, and aided the colonization society in procuring the territory forming the present republic of Liberia. On his return he was sent to the West Indies against the pirates. For several

years he took an active part in politics as a partisan of Gen. Jackson. In 1838 he served as flag officer in the Mediterranean, and in 1839 was made a captain and recalled. He was one of the earliest advocates of a steam navy, and drew the plans for the steam sloop of war Princeton, built at Philadelphia in 1842–'4, the explosion of one of the guns of which at Washington in 1844 caused the death of five persons, including the secretaries of war and the navy. In October, 1845, he was sent to the Pacific coast, where he took command, and in the following year conquered California and established the authority of the United States, returning overland in 1847. In 1849 he resigned his commission, and in 1851 was elected United States senator. He promoted the abolition of flogging in the navy, and resigned in 1853. His "Life, Speeches, and Letters" was published in 1856 (New York).

**STOCKTON, Thomas Hewlings,** an American clergyman, born at Mount Holly, N. J., June 4, 1808, died in Philadelphia, Oct. 9, 1868. He studied medicine in Philadelphia, but became a Methodist Protestant preacher, and was stationed at Baltimore in 1830. He was chaplain of the house of representatives from 1833 to 1835, and again from 1859 to 1861, and of the senate in 1862. In 1850–'55 he was associate pastor of St. John's Methodist church in Baltimore, and from 1856 of the church of the New Testament in Philadelphia. He compiled and published a Protestant Methodist hymn book, and issued the New Testament in paragraph form, and editions of the Bible, each book by itself. His other works include "Floating Flowers from a Hidden Brook" (Philadelphia, 1844); "The Bible Alliance" (Cincinnati, 1850); "Ecclesiastical Opposition to the Bible" (Baltimore, 1853); "Sermons for the People" (Pittsburgh, 1854); "The Blessing" (Philadelphia, 1857); "Stand up for Jesus," a ballad with notes, illustrations, and music, and a few additional poems (Philadelphia, 1858); "Poems, with Autobiographical and other Notes" (1862); "The Peerless Magnificence of the Word of God" (1862); "Influence of the United States on Christendom" (1865); and from his manuscript, after his death, "The Book Above All" (1870).—See "Memory's Tribute to the Life, Character, and Work of Rev. Thomas H. Stockton," by the Rev. A. Clark (New York, 1869), and "Life, Character, and Death of Rev. Thomas H. Stockton," by the Rev. J. G. Wilson (Philadelphia, 1869).

**STOCKTON-UPON-TEES,** a town of Durham, England, on the left bank of the Tees, 10 m. from its mouth in the North sea, and 220 m. N. N. W. of London; pop. in 1871, 27,598. The river is crossed by a fine bridge. The principal public buildings are the custom house, town hall, borough hall, mechanics' institute, and theatre. It is an important railway centre, and several branch lines bring in the produce of the numerous coal and lead mines in the vicinity. It has considerable commerce, and vessels of 300 tons can come up to the quays. The manufactures comprise sail cloth, rope, linen and worsted yarns, and iron and brass work, and there are ship yards, breweries, brick kilns, and corn mills.—Stockton was early a place of importance, and was the residence of the bishops of Durham. In 1325 it was ravaged by the Scots. In 1644 it was taken by the Scottish army, and in 1652 the castle was demolished.

**STODDARD,** a S. E. county of Missouri, bounded W. by the St. Francis and drained by the Castor river; area, about 800 sq. m.; pop. in 1870, 8,535, of whom 70 were colored. The greater portion of the county is level, and there are swamps and shallow lakes, the principal of the latter being Lake Nicormy, 25 m. long and 4 m. wide. It is a part of the "sunk country" produced by the earthquake of 1811. Large forests of cypress abound. It is intersected by the Cairo, Arkansas, and Texas division of the St. Louis and Iron Mountain railroad. The chief productions in 1870 were 34,501 bushels of wheat, 384,051 of Indian corn, 17,259 of oats, 29,708 of potatoes, 118,534 lbs. of tobacco, 9,138 of wool, 37,688 of butter, and 11,991 gallons of sorghum molasses. There were 2,295 horses, 2,560 milch cows, 1,286 working oxen, 4,206 other cattle, 6,765 sheep, and 26,558 swine. Capital, Bloomfield.

**STODDARD. I. Richard Henry,** an American author, born in Hingham, Mass., in July, 1825. His father, a sea captain, was early lost on a voyage, and the son for several years worked in an iron foundery in New York. In 1849 he privately printed a volume of poems, entitled "Footprints," followed by a maturer collection of "Poems" in 1852. In the latter year he received an appointment in the New York custom house, which he held till 1870. In 1853 he published "Adventures in Fairy Land," a book for young people, and in 1857 "Songs of Summer." His other works are: "Town and Country, and the Voices in the Shells," for children (New York, 1857); "Life, Travels, and Books of A. von Humboldt," with an introduction by Bayard Taylor (Boston, 1860; London, 1862); "The King's Bell," a poem (Boston, 1862; London, 1864; New York, 1865); "The Story of Little Red Riding Hood," in verse (New York, 1864); "The Children in the Wood," in verse (1865); "Abraham Lincoln, a Horatian Ode" (1865); "Putnam the Brave" (1869); and "The Book of the East," containing his later poems (1871). He has edited "Gen. Lyon's Political Essays, with his Life" (New York, 1861); "The Loves and Heroines of the Poets" (1861); J. G. Vassar's "Twenty-one Years round the World" (1862); "Madrigals, mostly from the Old English Poets" (1865); "The Late English Poets" (1865); a new edition with additions of Griswold's "Poets and Poetry of America" (1872), and of his "Female Poets of America" (1874); and the "Bric-à-Brac Series" (1874 *et seq.*). **II. Elizabeth** (Barstow), wife of the preceding,

born in Mattapoisett, Mass., in 1823. Since her marriage in 1852 she has published three novels, "The Morgesons" (1862), "Two Men" (1865), and "Temple House" (1867), all descriptive of New England life and scenery, and has assisted her husband in the editing of two or three annuals.

**STODDARD, Solomon**, an American clergyman, born in Boston in 1643, died in Northampton, Mass., Feb. 11, 1729. He graduated at Harvard college in 1662, was appointed "fellow of the house," and was the first librarian of the college from 1667 to 1674. In 1669 he became minister at Northampton, and was ordained Sept. 11, 1672. In February, 1727, Jonathan Edwards, his grandson, was elected as his colleague. In 1700 he published "The Doctrine of Instituted Churches," as an answer to the work of Increase Mather entitled "The Order of the Gospel," which occasioned an exciting controversy. He maintained that the Lord's supper is a converting ordinance, and that all baptized persons, not scandalous in life, though consciously unconverted, may lawfully partake of it. He also wrote "A Guide to Christ" (1714); "The Safety of appearing in the Day of Judgment in the Righteousness of Christ," which was reprinted at Edinburgh in 1792; and "The Trial of Assurance" (1796).

**STOICS** (Gr. *στοά*, porch), or philosophers of the porch, one of the speculative schools of antiquity, so called from the place at Athens (*στοά ποικίλη*) in which their founder Zeno gave his instructions (about 300 B. C.). Of their earlier representatives, besides the founder, the most prominent were Ariston of Chios, Cleanthes, Chrysippus, Zeno of Tarsus, Persæus, Herillus of Carthage, Sphærus, Diogenes the Babylonian, Antipater of Tarsus, and Posidonius and Panætius of Rhodes (about 130 B. C.); of their later, Seneca (died A. D. 65), Epictetus, Annæus Cornutus, Persius Flaccus, Musonius Rufus, Arrian, Marcus Aurelius, and many of the most distinguished Roman citizens. Originally treating the three departments of logic, physics, and ethics, they are chiefly known as moralists, since they connected philosophy intimately with the duties of practical life. In logic, they found the criterion of knowledge in sensuous impressions, which furnish the materials fashioned by reason, and combated skepticism by affirming that every representation of an object implies the existence of the object itself. In physics, they regarded God and the world as power and its manifestation, matter being a passive ground in which dwells the divine energy. Their ethics was a protest against moral indifference, and to live in harmony with nature, conformably to reason and the demands of universal good, and in the utmost indifference to pleasure, pain, and all external good or evil, was their fundamental maxim. (See MORAL PHILOSOPHY, vol. xi., p. 809.) An attempt to revive the stoic philosophy was made by Justus Lipsius (1547–1606), especially in his *Manuductio ad Stoicam Philosophiam* and *Physiologia Stoicorum.*—See Tiedemann, *System der stoischen Moral* (1776); Dourif, *Du Stoïcisme et du Christianisme* (Paris, 1863); O. Reichel, "The Stoics, Epicureans, and Skeptics" (translated from Zeller's *Philosophie der Griechen*, London, 1869); Weygoldt, *Zeno von Citium und seine Lehre* (Jena, 1872); and Wellmann, *Die Philosophie des Stoikers Zenon* (Leipsic, 1873).

**STOKES**, a N. county of North Carolina, bordering on Virginia, and drained by a branch of the Dan river; area, 550 sq. m.; pop. in 1870, 11,208, of whom 2,608 were colored. The surface is hilly and the soil fertile. Iron ore is abundant. The chief productions in 1870 were 33,450 bushels of wheat, 11,948 of rye, 171,214 of Indian corn, 36,353 of oats, 11,246 of Irish and 9,953 of sweet potatoes, 844,145 lbs. of tobacco, 6,381 of wool, 46,325 of butter, 37,050 of honey, and 7,421 gallons of sorghum molasses. There were 916 horses, 504 mules and asses, 4,928 cattle, 5,482 sheep, and 12,132 swine. Capital, Danbury.

**STOKES, George Gabriel**, a British mathematician, born in Skreen, Ireland, Aug. 13, 1819. He graduated at Cambridge in 1841, and was elected a fellow of Pembroke college. In 1849 he was appointed Lucasian professor of mathematics in the university. In 1851 he was chosen fellow of the royal society, and in 1852 contributed to its "Transactions" his celebrated paper "On the Change of the Refrangibility of Light," which gained the Rumford medal. He was elected president of the British association in 1869. He has published many papers on questions in pure mathematics and physics, particularly on the theory of light.

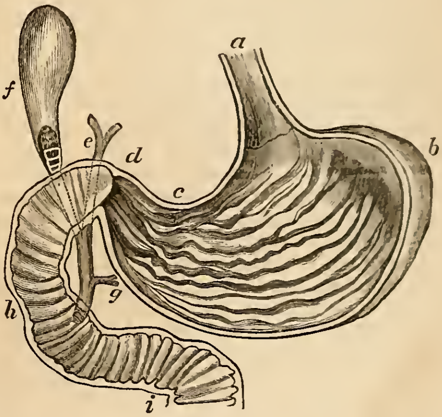
**STOKE-UPON-TRENT**, a parliamentary borough, town, and parish of Staffordshire, England, on the river Trent, 134 m. N. W. of London; pop. of the parish (including Hanley and other towns) in 1871, 89,262; of the parliamentary borough, 130,985. The town is the centre of "the Potteries," is well built, with numerous wharves and warehouses, and is intersected by the great trunk Trent canal and the North Staffordshire railway. Pottery is the principal manufacture, employing a large proportion of the population, and the place is famous for its china, porcelain, statuettes, and ornamental and encaustic tiles.

**STOLBERG. I. Friedrich Leopold**, count, a German poet, born at Bramstedt, Holstein, Nov. 7, 1750, died near Osnabrück, Dec. 5, 1819. After the death of his father, the Danish chamberlain Count Christian Günther, who was the first of his rank to liberate his serfs, his mother imparted a strong religious bias to his education. From 1770 to 1772 he studied at Halle, and subsequently at Göttingen, where he and his brother became prominent members of the *Dichterbund*. In his travels in 1775 he was with Goethe at Frankfort and other places, and next at Weimar, where he accepted an office at the court; but Klopstock

prevailed upon him to enter the service of the prince-bishop of Lübeck, who in 1777 sent him as envoy to Copenhagen. He married Anna von Witzleben in 1782, and resided at Eutin, where through his influence Voss became rector. In 1786 he was transferred to an office at Neuenburg in Oldenburg. After his wife's death in 1788 he sought solace in the society of the count and countess Reventlow at Emkendorf, and their influence made him more orthodox. Soon afterward he was appointed Danish ambassador at Berlin, and in 1790 he married the countess Sophia von Redern. He was appointed by the prince-bishop district governor at Eutin, but obtained leave of absence, and visited Münster, where he became acquainted with the ultramontane princess Amalia Gallitzin, and afterward Rome, where his growing partiality for Catholicism was greatly increased. Seven years later he and his whole family, excepting his elder daughter, formally joined the Catholic church (June 1, 1800). This alienated him from many of his former friends, especially from Voss, and his conversion influenced that of the younger Schlegel and the tone of other writers of the romantic school. He resigned his office at Eutin in the same year, and resided at Münster till 1812, when the surveillance to which his censure of the government subjected him drove him to a secluded locality near Bielefeld, and in 1816 he removed to his Hanoverian domain of Sondermühlen. His poetical works form the largest portion of the *Werke der Brüder Stolberg* (22 vols., Hamburg, 1821–'6). Among his other works are *Die Insel*, a prose romance developing the Utopian scheme of a model republic, dramas with choruses, translations of the Iliad and of parts of Plato, Æschylus, and Ossian, and *Geschichte der Religion Jesu Christi* (15 vols., Hamburg, 1811–'18; continued by Fr. Kerz to vol. xlv., Mentz, 1825–'46, and by Brischar to vol. lii., 1849–'59).—See *Der Graf Friedrich Leopold von Stolberg und seine Zeitgenossen*, by Menge (2 vols., Gotha, 1862). **II. Christian,** count, brother of the preceding, born in Hamburg, Oct. 15, 1748, died near Eckernförde, Schleswig, Jan. 18, 1821. He was associated with his brother at Göttingen, and shared in many of his poetical and other labors. He held an office at Tremsbüttel, Holstein, from 1777 to 1800. His wife, originally countess of Reventslow, figures in his poems as his beloved Louisa.

**STOLPE,** or **Stolp,** a walled town of Prussia, in the province of Pomerania, on the navigable river Stolpe, 10 m. from its mouth at the port of Stolpemünde on the Baltic, and 125 m. N. E. of Stettin; pop. in 1871, 16,280. It has a castle, three churches, a gymnasium, two hospitals, a house for invalids, and manufactures of amber, wool, linen, copper, hats, starch, tobacco, and leather.

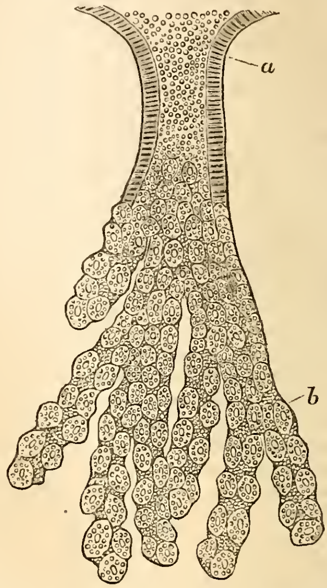
**STOMACH,** the hollow organ in which the first part of the function of digestion is performed in every perfectly developed animal. As a general rule, throughout the vertebrate animals we find a complex stomach associated with a vegetable diet; but this has striking exceptions, as in the dolphin, which has a multiple stomach with an animal diet, and the horse, which has a simple stomach with the same vegetable food as the ox. In man the stomach is the widest and most dilatable part of the alimentary canal; it is in the upper part of the abdomen, in the epigastric and part of the left hypochondriac region, below the diaphragm, above the arch of the colon and transverse mesocolon, and to a certain extent between the liver and spleen; it comes in contact in front with the anterior wall of the abdomen, and behind with the organs and vessels lying upon the spine. Its shape varies greatly, but when moderately distended, in or out of the body, resembles a bent cone, curved from before backward and from above downward, following its length; it lies almost transverse,



The Human Stomach laid open.—*a*. The œsophagus. *b*. The cardiac dilatation or great pouch. *c*. The lesser curvature. *d*. The pylorus. *e*. The hepatic duct. *f*. The gall bladder. *g*. The pancreatic duct, opening, together with the common biliary duct, into the duodenum. *h i*. The duodenum.

a little obliquely downward, forward, and to the right; the anterior border is the greater curvature, and is lodged between the folds of the great omentum; the œsophagus enters at about one quarter of the length from the left extremity; the great *cul-de-sac* on the left is united to the spleen by short vessels. The "pylorus" is the constriction between the smaller extremity of the stomach, directed toward the right, and the commencement of the duodenum. The average capacity of the stomach is regarded as about five pints; but this varies very much according to the age and habits of the individual, and even according to the alternating conditions of fulness or vacuity. When filled with food, the stomach becomes more horizontal, so that its great curvature looks forward and its lesser curvature backward.—The stomach is composed of four distinct coats or tunics: 1. The external or peri-

toneal coat is a thin serous layer covering the outside of the organ, continuous with the general peritoneal layer of the abdomen. Its moist and smooth external surface enables the stomach and other neighboring organs to glide readily over each other without friction or injury. 2. The muscular coat, immediately beneath the peritoneal covering, is composed of a double series of circular and longitudinal muscular fibres, of the smooth or unstriped variety, whose involuntary alternating contractions and relaxations cause the peristaltic movements of the walls of the stomach, and provide for the requisite mixture, transportation, and final expulsion of its contents. 3. The submucous cellular coat is a layer of loose areolar tissue, between the muscular coat and the mucous membrane. The office of this layer is to form such a connection between the muscular and mucous tunics as to keep them in a certain degree of apposition, and yet allow of the folding up of the mucous membrane when the organ is empty, and its expansion when filled with food. 4. The mucous membrane of the stomach, its most important tunic in a physiological point of view, is the membrane which secretes the gastric juice. Its internal surface is soft and velvety, owing to its being covered with minute conical folds or ridges which are partly distinct and partly connected with each other. Its thickness is composed of a great number of tubular glands or follicles, the "gastric tubules," which begin at the inferior portion of the mucous membrane by blind extremities, run perpendicularly through its substance, and open by minute orifices upon its free surface into the general cavity of the stomach. These tubules vary somewhat in different parts of the stomach. In the pyloric or right-hand portion they are nearly straight and simple in structure, and of the same diameter throughout. In the cardiac or left-hand portion they are more compound, several of them uniting, at a little distance below the surface, into comparatively wide circular tubes, lined with cylindrical instead of glandular epithelium. In the middle region of the stomach the gastric glands are also compound; and their inferior or tubular portions, which are here very long, are filled, in addition to the ordinary glandular epithelium, with very large, rounded, granular, nucleated cells, which often seem to fill nearly their entire cavity, and to project from their sides in such a way as to give them an irregularly tumefied or varicose appearance. The mucous membrane of the stomach is exceedingly vascular, the capillary blood vessels penetrating everywhere between the adjacent tubules, and forming an abundant superficial plexus about their orifices. At the time of digestion the quantity of blood circulating in the mucous membrane is greatly increased by an expansion of the smaller arteries supplying the capillary network. The mucous membrane becomes turgid and reddened, the gastric tubules enter into a state of functional activity and begin to pour out the gastric juice, which is to act upon the food. Soon afterward the muscular coat of the organ is in its turn excited to peristaltic action, by which the food is



Compound Gastric Tubule, from the middle region of the Stomach. *a*. Upper or wide portion, lined with cylindrical epithelium. *b*. Lower or tubular portion, lined with glandular epithelium.

moved alternately to and fro, from the cardiac toward the pyloric extremity of the organ, and subjected also to a kind of gentle and continuous churning process by which the gastric juice exuded from the mucous membrane is made to penetrate every part of the alimentary mass, and come in contact simultaneously with the whole. As digestion proceeds, successive portions of the liquefied food are carried through the pylorus into the small intestine; and as the stomach is thus gradually emptied it resumes its previous condition of repose. The peristaltic motion comes to an end, the vascular congestion subsides, and the further secretion of gastric juice is suspended until the next period of digestion arrives.

**STOMACH, Diseases of the.** Diseases of the stomach may be classed as inflammatory, structural, and functional. Gastritis or inflammation of the stomach may be acute, subacute, or chronic. It is always attended by certain symptoms, but they are also mostly the symptoms of other diseases. Vomiting is frequent and persistent, but is of itself not sufficient evidence, nor when associated with pain in the epigastric region. The following combination of symptoms may be considered as diagnostic: intense pain of a burning character over the epigastrium, together with shooting pains in the chest, unaccompanied by the physical signs of pulmonary disease, nausea, and

vomiting of muco-serous matter tinged with bile and often with blood, the act causing intense suffering. The thirst, though not always present, is often so great as to be almost insupportable. The pulse is frequent, small, and wiry. The temperature of the skin is generally considerably raised. The bowels are constipated except in cases of poisoning.—Acute gastritis is caused by traumatic injuries and by irritant poisons; also by excessive indulgence in alcoholic drinks. Over-eating and the eating of indigestible food are also causes. The treatment does not involve much medication; rest, cooling drinks, light bland food, and the administration of nourishing enemas with sometimes small quantities of opiates, are the chief reliances. Lime water and milk may sometimes be taken better than almost anything else. Wine may be given by the mouth or spirits by the rectum.—Subacute gastritis is generally more or less transient. When attended with considerable fever, the affection is sometimes called "gastric fever;" but this term is indefinite, and is also applied to cases of what are called "abortive typhoid fever," in which the symptoms for the first few days are like those of typhoid fever and then cease. It is often the consequence of errors in diet, either of over-eating or of eating improper food, and frequently follows a debauch. There is tenderness in the epigastric region and a furred tongue. Pain in the head is often a prominent symptom, frequently accompanied by nausea. The pulse is usually feeble and the extremities cold. If the inflammation approaches the acute character, the symptoms are heightened in proportion. Rest, abstinence from food for a time, bland and nutritious diet, regulation of the intestinal evacuations by enemas, the application of sinapisms or other counter-irritants or of warm water dressings over the epigastrium, and the administration of demulcents, as flax-seed tea, and also small pieces of ice, are ordinarily indicated. Subacute gastritis is frequently connected with acute dyspepsia, in which case it is often designated by the indefinite term "bilious attack," although the term is generally an improper one, as the liver is not usually particularly implicated. There is congestion of the mucous membrane of the stomach, in which that of the intestines finally participates, with active diarrhœa and sometimes severe colic. The treatment includes the unloading of the stomach and bowels, with sometimes the administration of anodynes, particularly chloroform.—Chronic gastritis may come on gradually, or it may follow the acute or subacute form. Its symptoms are liable to be mistaken for those of functional disorder which constitute dyspepsia. The causes are errors in diet, poisonous or irritating substances, excessive drinking of alcoholic liquors, poverty of the blood, irregularity in the circulation, and diseases of other organs. The treatment is rest of the organ, gentle exercise of the body, nutritious but easily digestible food, tonics, counter-irritants, bathing with after friction of the skin, and sometimes the administration of pills of nitrate of silver or of powders of subnitrate of bismuth.—The structural diseases of the stomach are induration, softening, ulceration, cancer, degeneration of the gastric follicles, and dilatation. Induration or sclerosis of the stomach is due to a morbid fibrous growth in the submucous areolar tissue, involving thickening of the coats of the organ. It is probably caused by chronic inflammation of the submucous areolar tissue. The affection may involve a part or the whole of the organ. When limited in extent the pylorus is the part usually affected, a condition liable to produce stricture and render the case dangerous from retention of food. It is a rare affection, scarcely ever attacking those who are under 40 years of age. Its symptoms are liable to be mistaken for those of cancer, but its long continuance without the rapid progress of cancerous disease, and also its appearance in other organs, are diagnostic. It is generally regarded as chiefly occurring in hard drinkers. The treatment is abstinence from spirits and other stimulants, and a nutritious and well regulated diet.—Softening of the stomach may be the result of inflammation, but there are cases of non-inflammatory origin. The softening may be confined to the mucous coat, or it may involve all the others. Non-inflammatory softening is probably sometimes caused by defective nutrition of the membrane.—Ulceration of the stomach is one of the sequelæ of acute gastritis, but it may follow inflammation limited to the space of the ulcer. The ulcer varies in size, sometimes being so small as not to be easily found, or it may be an inch or more in diameter. The disease may prove fatal from perforation, from hæmorrhage, or from inanition. Its duration is variable, and it is often curable. The treatment should include as much rest as possible for the stomach consistent with nutrition.—Cancer attacks the stomach about as frequently as it does other parts, but it is in this situation nearly always primary; that is, the affection does not make its appearance previously in any other part. The pylorus is the situation mostly attacked, and the disease does not then usually pass into the duodenum. When however the cardiac end of the organ is the seat, the cancer generally also more or less affects the œsophagus. The cancer is generally of the hard variety known as scirrhus. The affection is attended with the peculiar lancinating pains of cancer, and vomiting is frequent, although less so than in simple ulcer. Blood is often found with the vomited matter, generally having the appearance of coffee grounds, and sometimes contains purulent matter. These symptoms are accompanied by progressive anæmia and loss of weight.—Degeneration of the gastric follicles has been found a more frequent affection than was formerly suspected, and is the accompaniment of many

cases of dyspepsia. The treatment should be mainly constitutional, including good air and nutritious diet.—Dilatation of the stomach is usually caused by obstruction of the pylorus, but it sometimes, though rarely, occurs without it. The organ often becomes enormously distended, and filled with undigested and fermented matter, and the muscular coat exceedingly thin. Regulation of the diet is the proper treatment.—The most important functional diseases of the stomach are dyspepsia and gastralgia. (See DYSPEPSIA.) Gastralgia is a painful nervous affection, sometimes of the most excruciating nature. It often accompanies dyspepsia, and sometimes the structural diseases. When existing alone and in an acute form, it may be caused by the presence of obnoxious ingesta. It sometimes results from malaria, frequently accompanies intermittent fever, and is sometimes associated with gout. It rarely attacks old persons or those under the age of puberty. Prof. Alfred Stillé states that it is often produced by chewing tobacco. The remedies during the attack are anodynes. Morphine may be given by the mouth or by hypodermic injection. Bismuth has been used, it is said, with good results, but it is not generally relied on. A few drops of chloroform with water often give speedy relief. The general treatment will depend upon regulating the bodily functions and the diet. When of a malarious origin the preparations of quinia are indicated, in full doses.

**STONE.** See ROCKS.

**STONE**, the common name of calculus in the urinary bladder, for the composition of which see CALCULI and GRAVEL. The prominent symptoms are irritability of the bladder with frequent irresistible desire to pass water, and occasional stoppage of the stream, with pain in various parts of the urinary system, and sometimes the presence of blood, mucus, and pus in the urine. None of these, however, can be depended on, the only sure diagnosis resting on making the stone perceptible to the ear and fingers by means of a metallic sound introduced through the urethra, and brought into direct contact with the foreign body; even with this instrument, several introductions in various positions of the body are sometimes necessary for its detection. The symptoms vary in intensity according to the size and roughness of the stone, the state of the urine, and the condition of the bladder. Stone is formed by a precipitation of the urinary salts either in the kidney, passing thence to the bladder, or primarily in the bladder. In the latter case a foreign body may be the nucleus. Stone may be removed from the bladder by—1, solution; 2, extraction as a whole through the urethra; 3, extraction through an opening artificially made into the bladder (lithotomy); 4, crushing into fragments of such a size that they can pass through the urethra (lithotripsy). 1. Solution may be attempted by remedies taken by the mouth or injected into the bladder. Uric acid calculi have been treated by the administration of alkalies, and the phosphatic by the injection of a solution of nitric acid. These methods have from their inefficacy fallen into disuse. 2. Extraction by the urethra is now done only in females; in them the canal is so short and dilatable that a stone of considerable size can be removed by this method. 3. Lithotomy is indicated in all males under puberty, and in others when the stone is large or there are several; when the urethra is strictured; when the bladder is in such a condition as to be unable to bear the repeated introduction of instruments, and the irritation caused by the fragments resulting from lithotripsy; and when the kidneys are not much diseased. The operation may be done by incision above the pubes (the supra-pubic), through the perineum (the perineal), or through the rectum, or rectum and perineum (the recto-vesical). The supra-pubic and that through the rectum and perineum are usually employed only in cases in which, from the size of the stone or other causes, removal through the perineum is impossible. The perineal operations are three in number, the lateral, bilateral, and median. The lateral operation is in general the best, and it may be performed as follows: A grooved steel staff or sound of full size is introduced, the bladder being moderately distended, the patient on his back, with shoulders elevated, thighs separated widely in order to expose the perineum, and the hand grasping and bound to the foot; the patient being etherized, an incision is made on the left side of the perineum from about an inch before the anus downward and outward to a point midway between the anal opening and the tuberosity of the ischium, the muscular fibres being divided down to the staff; the left index finger passed into the wound keeps back the rectum, and at the same time feels at the membranous part of the urethra the groove, which is entered by the knife and conducts it to the bladder, the urethra and about half an inch of the prostate being divided; the finger is then introduced, dilating the opening; the finger being withdrawn, the forceps are introduced, opened, and the stone seized, if possible, with the first gush of fluid from the wound, and then extracted by slow, steady, and undulating movements, dilating and not tearing the soft parts. If properly performed, and the after treatment not interfered with by hæmorrhage, inflammation, sloughing, or other complications, the urine begins to flow by the urethra in about a week, and the wound heals completely in four or five weeks. In the bilateral operation, a curved incision, with the convexity upward, is made from one side of the perineum to the other, between the anus and the urethral bulb, dividing both sides of the prostate by a double bistoury. The median operation differs from the preceding in that the incision is vertical and in the median line, and the prostate is not cut, but is dilated, and somewhat lacerated, by

the finger introduced through the opening made into the urethra in front. The recto-vesical operation consists in cutting into the bladder from the rectum on the median line behind the prostate, or in dividing also the prostate and perineum in the median line. In the high operation the bladder is opened above the pubes through the linea alba, where there is no covering of peritoneum. Lithotomy was practised 25 centuries ago; Hippocrates bound his pupils by oath not to practise it, but it came into use again in the time of Celsus, in whose writings are found the first indications of the bilateral operation; the lateral operation was first practised toward the end of the 17th century; the supra-pubic method was first employed by Franco in the 16th century, and the recto-vesical by Sanson in the 19th. 4. Lithotripsy (more commonly called lithotrity) is indicated in patients beyond puberty, when the stone is single and not large, and when the urethra is not strictured, and the bladder and kidneys are not much diseased. The early instruments used for this purpose were very rude and dangerous, the stone being grasped by branches made to protrude from a straight catheter, and then bored by a drill extending through the instrument and worked by a watchmaker's bow; after it was bored it was crushed by another complicated instrument. To Civiale (1817–'24) is unquestionably due the credit of having introduced the operation by improving the instruments and the manner of their use. The instrument now used is composed of two sliding blades, introduced in the shape and after the manner of a sound, between which the stone is seized, and then crushed by the gradual pressure of a screw; the fragments may then be washed out by injections or by the urine, large pieces being again broken by the same or a smaller instrument. In properly selected cases, and with skilful manipulation, this operation is much safer than lithotomy.

**STONE.** **I.** A N. county of Arkansas, bounded N. E. by White river, and watered by the Little Red river. It was formed in 1873 from portions of Independence, Izard, Searcy, and Van Buren counties. The surface is irregular. The soil produces cotton, grain, tobacco, and fruits. Timber is abundant. Iron, lead, and marble occur. Capital, Mountain View. **II.** A S. W. county of Missouri, bordering on Arkansas, intersected by White river, and drained by its tributary the James; area, about 500 sq. m.; pop. in 1870, 3,253, of whom 20 were colored. The surface is broken, and the soil fertile. The Atlantic and Pacific railroad touches the N. W. corner. The chief productions in 1870 were 13,022 bushels of wheat, 121,735 of Indian corn, 14,340 of oats, 3,205 lbs. of tobacco, 3,521 of wool, 27,817 of butter, and 3,808 gallons of sorghum molasses. There were 1,298 horses, 905 milch cows, 1,683 other cattle, 3,023 sheep, and 10,722 swine. Capital, Galena. **III.** An E. county of Dakota, recently formed and not included in the census of 1870; area, about 700 sq. m. It is mostly table land, and has a rolling surface.

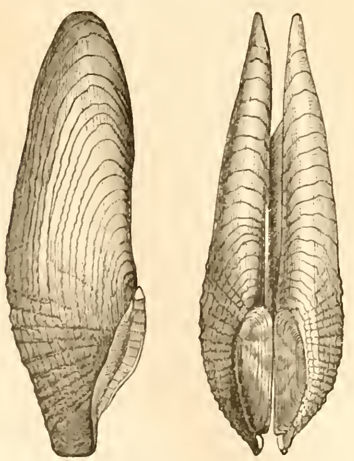
**STONE, Marcus.** See p. 898.

**STONE, Thomas,** a signer of the Declaration of Independence, born at Pointon Manor, Charles co., Md., in 1743, died at Port Tobacco, Md., Oct. 5, 1787. He was a lawyer, and was sent as a delegate to congress in 1774 and 1775. He strongly favored the establishment of an independent government, although under instruction from the Maryland convention to oppose it; but that state receded from its opposition in time to allow its delegates to sign the Declaration. He served on the committee to prepare a plan of confederation, and was reëlected to congress in 1777 and 1783.

**STONE.** **I. William Leete,** an American author, born at New Paltz, N. Y., April 20, 1792, died at Saratoga Springs, Aug. 15, 1844. He was a printer, and edited successively the "Herkimer American," "Hudson Whig," "The Lounger" (Hudson), "Albany Daily Advertiser," "Hartford Mirror," "The Knights of the Round Table" at Hartford, and from 1821 the New York "Commercial Advertiser." In 1843–'4 he was superintendent of common schools in New York. His principal works are: "History of the Great Albany Convention of 1821" (8vo); "Narrative of the Grand Erie Canal Celebration" (New York, 1825); "Letters on Masonry and Anti-Masonry" (1832); "Matthias and his Impostures" (12mo, 1832, and 18mo, 1835); "Tales and Sketches" (2 vols. 12mo, 1834); "Essays on Social and Literary Topics" (12mo, 1835); "Ups and Downs in the Life of a Distressed Gentleman" (12mo, 1836); "Life of Maria Monk and Refutation of the Awful Disclosures" (8vo, 1836); "Letters on Animal Magnetism" (8vo, 1837); "Life of Joseph Brant" (2 vols. 8vo, 1838; new ed. by W. L. Stone, jr., with index, Albany, 1865); "Border Wars of the American Revolution" (2 vols. 12mo, 1839); "Poetry and History of Wyoming" (12mo, 1841; with index, 1864); "Life of Red Jacket—Sa-go-ye-wat-ha" (8vo, 1835 and 1841; new ed. with a life of the author by W. L. Stone, jr., 1866); and "Life of Uncas and Miantonomoh" (24mo, 1842). **II. William Leete,** jr., son of the preceding, born in New York, April 4, 1835. He graduated at Brown university in 1858 and at the Albany law school in 1859, and is now (1876) one of the editors of the "New York School Journal." He has published "Life and Times of Sir William Johnson, Bart.," begun by his father (2 vols. 8vo, 1865); "Life and Writings of Col. William L. Stone" (1866); "Saratoga and its Mineral Springs" (1866); "History of New York City" (1872); "The True History of the Jane McCrea Tragedy" (1874); "Reminiscences of Saratoga" (1874); and "Centennial Sketches" (1876). He has translated from the German the "Memoirs and Letters of Mrs. General Riedesel" (1867), and the "Life and Military Journals of Major General Riedesel" (2 vols. 8vo, 1868).

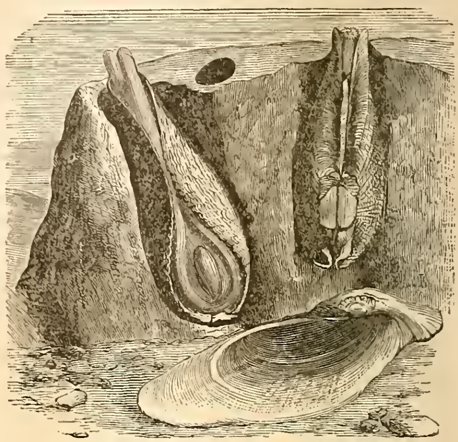
**STONE, William Oliver,** an American painter, born in Derby, Conn., Sept. 26, 1830, died in Newport, R. I., Sept. 15, 1875. He studied under Nathaniel Jocelyn in New Haven, lost all his early pictures by the burning of his studio, and removed to New York in 1851. His first picture exhibited in the national academy was "The Mantilla" (1854), and he afterward painted many portraits of prominent persons, being especially successful in those of women and children. He became a member of the national academy in 1859.

**STONE BORER,** a name given to several bivalve shells, especially *pholas* (Linn.) and *lithodomus* (Cuv.), from their power of boring into the hardest rocks. The *pholadidæ* (Gr. *φωλεύειν*, to hide in a hole) are true bivalves, and have two accessory plates in the neighborhood of the hinge for the protection of the dorsal muscles; they belong to the group *siphonophora* (Gray), or those having long respiratory siphons, united for the greater part of their length; they are all burrowing animals, penetrating the hardest substances. The shells are usually elongated, gaping at one or both ends, and closed by two adductor muscles; the foot is large and powerful, and the mantle is closed; they are found in all climates. The typical genus *pholas* is often of considerable size, with a white, hard, rough, but very brittle shell, rendering it an interesting question how it can perforate a solid rock; the operation is supposed to be performed by a rotatory motion of the shell effected by the powerful foot. The date shell or piddock (*P. dactylus*, Linn.), about 2 in. long and 6 or 7 in. wide, is found along the European coast, mostly in calcareous rocks; it is eaten along the Mediterranean. It is very luminous, and hence some have supposed that its excavations may



Date Shell (Pholas dactylus).

be partly due to electrical action on the sea water. The smaller *P. candida* (Linn.) is used for bait in England. The *P. crispata* (Linn.) is found along the coasts of our middle and southern states. Many fossil species are known. The family of *veneracea*, of the same group, are also stone borers, principally by means of



Stone Borers (Pholas dactylus) which have hollowed out shelters in a block of gneiss.

the foot.—Among the asiphonate bivalves, the most remarkable stone borer is the *lithodomus lithophagus* (Cuv.); it is commonly found in holes which it has excavated in calcareous and coral formations; it is the sea date shell of the Mediterranean, and is a delicate article of food. Its perforations have served as important indications of the change of level of the sea coast in modern times; the columns of the temple of Serapis at Pozzuoli are perforated by these shells at a considerable height above the actual level of the sea.—Another bivalve, coming near the clams, generally considered a stone borer, is *saxicava* (Lam.), which appears under such a variety of forms that two genera and at least 15 species have been made of the single representative, *S. rugosa* (Lam.); the young symmetrical form constitutes the genus *hiatella* (Bosc). It is found in almost all parts of the world, largest in the arctic seas, in crevices of rocks and corals, assuming very exactly the shape of the cavity which contains it; it occurs from low-water mark to the depth of 140 fathoms; it is found fossil in the miocene and glacial deposits. It has been questioned whether *saxicava* is the excavator of the holes in which it is found, and the subject of the mechanism by which the stone borers operate is by no means well understood.—Sea urchins also may in many instances be called stone borers, the excavation of their cavities being effected by the constant action of their spines, and perhaps also by the vibratile cilia of their ambulacral tubes and suckers. It is conceivable, if not probable, that the continual action of soft vibratile cilia may excavate holes even in the hardest rocks.

**STONE CHAT** (*saxicola rubicola*, Bechst.), a dentirostral bird of the warbler family, and

subfamily *erythacinæ*, or old world robins. The bill is short, with broad gape, furnished with bristles; wings long and rounded, with fourth and fifth quills equal and longest; tail short and broad; tarsi and toes slender, and

Stone Chat (Saxicola rubicola).

hind toe long. There are several species. The stone chat, resident in England but migratory on the continent, is about $4\frac{1}{2}$ in. long; the head, throat, and back black, on the latter edged with whitish red; sides of neck, upper part of wings, and rump white; breast orange brown; lower parts reddish white. A similar but migratory species is the whin chat (*S. rubetra*, Bechst.), so named for its partiality for furze or whin bushes. These two species belong to the subgenus *pratincola* (Koch).

**STONE CROP.** See SEDUM.

**STONEHENGE,** a collection of huge stones on Salisbury plain, Wiltshire, England, about 8 m. N. of Salisbury. Its name is old Saxon, and signifies "hanging stones." Seen from a distance, they appear to be merely an irregular

Stonehenge.

mass of stones, but a closer inspection shows them to have been originally arranged to form two ovals within two circles, surrounded by a bank of earth 15 ft. high and 1,010 ft. in circumference. There are altogether about 140 stones, weighing from 10 to 70 tons. They are much weather-worn, but in many of them the sharp angles and the tenons and mortices by which they were joined are well preserved. The outer circle has 17 stones remaining out of 30; the inner has but 8 stones entire, and fragments of 12 others. The inner oval consisted of about 20 smaller stones, of which 11 are still standing; the other oval consisted of 10 stones, of which 8 are remaining. Scattered over the plain are about 300 tumuli, or barrows, some of which have been opened, and found to contain charred human bones, fragments of pottery, and British and Roman ornaments and weapons. In the centre is a flat slab 15 ft. long, which is supposed to have been the altar; it is a grained calcareous sandstone, which strikes fire with steel. On excavating at the foot of this altar, remains of oxen, deer, and other animals were found, intermixed with burnt wood and fragments of Roman and British pottery. According to Geoffrey of Monmouth, Stonehenge was erected by order of Aurelianus Ambrosius, the last British king, in honor of 460 Britons slain by Hengist the Saxon; but Polydore Vergil argues that it was a monument to the memory of that king. Some authorities believe it to have been a druidic temple, others assert that it was an astronomical observatory, and others that it was a place both of worship and of council, which was also used for assemblies of the people. Similar stone circles have been found in various parts of the world, and Sir John Lubbock refers them all to the bronze age, while other antiquaries and geologists maintain that some of them were erected 10,000 to 50,000 years ago. Nothing has as yet been brought forward to establish any of these theories beyond controversy and doubt.

**STONE RIVER, Battle of.** See MURFREESBORO.

**STONINGTON,** a town, borough, and port of entry of New London co., Conn., on Long Island sound, at the S. E. extremity of the state; pop. of the town in 1870, 6,313, of the borough, 1,561. The town is divided into five voting districts, Stonington borough, the villages of Mystic, Mystic Bridge, and Pawcatuck, and the "Road." The borough is built on a narrow rocky point extending about half a mile into the sound, and has a good harbor protected by a breakwater. A second breakwater is now building and a third one is projected. Stonington is a favorite place for summer resort, and has a considerable coasting trade and several vessels employed in sealing. It is connected with Providence by the Stonington and Providence railway, with New London by a branch of the same, and with New York by the New York and Stonington steamboat line. Mystic Bridge is a thriving village, chiefly engaged in ship building. There are in the several villages four banks, a savings bank, 14 churches, 16 public schools, three woollen mills, one cotton mill, a large foundery and machine shop, and several other factories, and a weekly newspaper. On June 30, 1874, its

shipping amounted in the aggregate to 119 vessels of 16,978 aggregate tonnage.—The town was settled in 1649, and the borough was incorporated in 1801. On Aug. 9 and 10, 1814, the borough was attacked by the British fleet under Sir Thomas Hardy, but it was compelled by the volunteers and militia to retire.

**STONY POINT,** a small rocky promontory on the right bank of the Hudson river, in Rockland co., N. Y., 42 m. N. of New York, at the entrance of the Highlands, and opposite Verplanck's Point. On both these points forts were built by the Americans during the revolution, which were captured by Sir Henry Clinton about the first of June, 1779, strengthened, and garrisoned; but that on Stony Point was retaken by a bold night attack under Gen. Anthony Wayne, with 1,200 men, July 16, and the garrison of 543 officers and men made prisoners. The Americans had 15 killed and 83 wounded, and the British 63 killed. The simultaneous attack on Verplanck's Point having failed, the works on Stony Point were destroyed and abandoned on the 18th.

**STOPPAGE IN TRANSITU,** in law, the arresting by the seller of goods on their passage to a distant purchaser who has become insolvent. When and how the doctrine of stoppage in transitu became a part of our law cannot be definitely asserted. Its introduction was comparatively recent. The right exists only between a buyer and a seller. A surety for the price of the goods, bound to pay for them if the buyer does not, has not this right; but one who is substantially a seller has. Thus, one ordered by a foreign correspondent to buy goods for him, and then buying them in his own name and on his own credit, and sending them as ordered, may stop them *in transitu.* So may a principal who sends goods to his factor, or one who remits money for any particular purpose. The reception and negotiation of a bill for the goods does not defeat the right, nor does part payment. But goods cannot be stopped when they are sent to pay a precedent and existing debt.—The right arises only upon actual insolvency, which need not be legal or formal bankruptcy or insolvency. It is enough if the buyer cannot pay his debts, and also that he refuses to comply with the specially agreed terms of the sale, for this is insolvency so far as the seller is concerned. When the goods are stopped, the buyer may, by payment of the price or by tender of security if they were sold on credit, defeat the stoppage and reclaim the goods. If the seller stop the goods maliciously, and without actual belief of the insolvency on good grounds, he would doubtless be answerable for any damages which the buyer might sustain. The seller's right to stop the goods cannot be defeated by any sale or mortgage thereof by the buyer, or by any claim or lien or attachment of any other person, except such lien as may arise in favor of any carrier by whom they have been conveyed.—Nice questions have arisen in respect to the *transitus.* Generally speaking, the goods are in transit when they are not in the actual possession either of the buyer or of the seller. But the law goes sometimes further than this, and inquires into the constructive possession; for the goods may be in the actual possession of the seller, and yet so far constructively in the possession of the buyer that the seller cannot retain them; or they may be in the actual possession of the buyer, but under such circumstances that the seller's right is not taken away. It becomes, therefore, very important in many instances to ascertain whether the transit is complete. A carrier of goods, by land as well as by sea, acquires a lien on the goods which he carries for the freight money. The goods are still in transit, and may be stopped, so long as the carrier withholds them from the buyer by his lien for the freight, and a seller who seeks to stop them then must discharge this lien. In general, whenever a carrier enters into a new arrangement with the consignee, by which he agrees to hold the goods as the property of the consignee and at his disposal, there is a termination of the transit. Yet all acts in reference to such question must be open to explanation by existing circumstances, the general inquiry in such case being whether the carrier, warehouseman, wharfinger, or other person having actual possession of the goods at the time of the intended stoppage in transitu, was then acting as the agent of the seller or of the buyer; for if of the latter, the transit was terminated. If the buyer order the goods to be sent to some other person by any suitable conveyance without designating any one especially, or by a designated carrier who is not specifically his agent or servant, the goods remain in transitu until they reach that second person. Questions of constructive possession arise very frequently in respect to goods in the charge of warehousemen. In general, every warehouseman is the agent of any party who puts the goods in his warehouse and can take them out at his pleasure; and therefore his possession is the possession of such party. On this point it is a material question whether anything remains to be done by the seller; if nothing, this goes far to make the warehousing a delivery to the buyer. If a seller of goods that are warehoused delivers an order for them to a buyer, this alone may not transfer the possession; but if the buyer delivers the order to the warehouseman, this in general transfers the possession, and still more so if the warehouseman enters the same in his books or otherwise accepts the order, so as to be responsible for the goods to the buyer. If the buyer sells to a third party, to whom the warehouseman certifies that the goods are transferred to his account, and who thereupon pays the price, the warehouseman becomes responsible to this third party; and if the original seller, though there remained something material to be done by him to the goods, consented to the warehouseman's so certifying, he would be held to

have lost his right of stoppage in transitu.—The effect of the bill of lading upon the right of a seller to stop the goods in transitu is very important. The law regards the bill of lading, not as a mere receipt which the carrier gives for the goods, but rather as a muniment of title, carrying property with it, and being itself *quasi* negotiable. An indorsement and delivery of the bill for value operate as a symbolic delivery of the goods mentioned in it. It results from this doctrine that a consignee, who sells for value goods to arrive and indorses over the bill of lading, confers upon the purchaser a title and property which destroy the right of the seller of the goods to stop them *in transitu.* But if the party buying from the consignee knows that the sale is in fraud of the original seller, it is voidable by that seller of course; and if he knows that the consignee is, or is about to become, insolvent, this knowledge would probably have the same effect, as would also knowledge or notice of any circumstances which rendered the bill of lading not properly assignable. If the bill of lading be transferred and indorsed by way of pledge to secure the consignee's debt, the consignor does not lose entirely his right to stop the goods, but holds it subject to the rights of the pledgee; that is, he may enforce his claim to hold the surplus of the goods after the pledgee's claim is satisfied, and he holds this surplus to secure the debt of the consignee to him.—The insolvency of the buyer, however complete or however manifested, will not operate of itself as a stoppage in transitu. The goods must be actually stopped, in some way which the law recognizes as adequate, by the seller or his authorized agent. An actual taking possession by the seller is not necessary, at least not in all cases, although actual possession should be taken if possible, and as soon as possible. A constructive possession may be acquired by giving notice to the carrier or warehouseman, forbidding him to deliver the goods to the buyer, and requiring him to give them up to the seller or his agent, or to hold them subject to his order. Delivery in disregard of this notice does not defeat the seller's right; he has still a constructive possession, and the carrier is responsible to him for all the injury he may sustain. Or, if the buyer becomes insolvent, and the goods pass into the possession of his assignees, the seller may maintain an action of trover against them. What the consignor may do personally, he may do by his agent; and if the demand be made by one who acts as agent, but without authority, a subsequent adoption and ratification will have the effect of a previous authority, provided this be made before the goods are demanded by the buyer.

**STORAX.** See Balsams.

**STOREY,** a W. county of Nevada, bounded N. by Truckee river and S. by the Carson; area, 420 sq. m.; pop. in 1875, 19,528, of whom 1,341 were Chinese. The valleys of the rivers contain small tracts of arable land, but the county derives its importance from the Comstock lode, on Mt. Davidson (7,000 ft. high), the richest silver-bearing lode in the world. In 1870 there were 19 quartz mines, producing gold and silver to the value of $7,751,331; but the production has since very greatly increased. There were 3 manufactories of boots and shoes, 3 of carriages and wagons, 5 of furniture, 3 of iron castings, 3 of jewelry, 4 of machinery, 3 of saddlery, 4 of tin ware, 8 breweries, and 26 quartz mills. Capital, Virginia City.

**STOREY, George Adolphus.** See p. 899.

**STORK,** a wading bird of the heron family, subfamily *ciconinæ*, and genus *ciconia* (Linn.); other allied genera are the jabiru and marabou, described under their own names. In the storks the bill is long, straight, strong, gradually tapering to a sharp tip; sides compressed; wings long and ample, the third and fourth quills the longest and equal; tail short and broad; tarsi long and scaled; toes short and stout, webbed to the first joint; hind toe elevated, partly resting on the ground. They are large, most abundant in warm countries, and performing periodical migrations to and from the marshy regions of Europe, Asia, and Africa; like vultures and other carrion feeders, they eat almost any kind of garbage that comes in their way, and are hence valuable scavengers in hot climates; they seek their food on the borders of streams; the body is light and well balanced; during flight the head is thrown back and the legs are extended; the space round the orbits is destitute of feathers, and in some the whole face and throat are naked. There are about a dozen species, of which the best known is the white stork (*C. alba*, Briss.);

White Stork (Ciconia alba).

it is 3½ ft. long, the bill 7¾ in.; the general color is white, with the quills and wing coverts black, and bill and feet red; around the eyes a bald blackish circle; it is the *cigogne* of the French. They arrive in N. Europe, especially in Holland and Germany, in the spring, return-

ing in the autumn to Africa by night and in large flocks; the only noise they make is by clapping the mandibles together like a pair of castanets; they rest sleeping on one leg, with the neck folded and head turned backward on the shoulder. The food consists of reptiles, fish, young birds, and insects. The nest is large, coarsely made of sticks and twigs, placed on housetops (often in the midst of crowded cities), and is repaired by the males year after year; the eggs are three or four, white tinged with buff, $2\frac{5}{6}$ by 2 in.; both sexes incubate, and the young are hatched in about a month; the nestlings are tenderly cared for, and are fed by food regurgitated from the parents' stomachs. The flight is very high, and the gait slow, with long and measured steps; the disposition is gentle, the manner familiar, and the docility considerable; they do not propagate in captivity. The stork was considered by the ancients as the personification of piety, conjugal and filial love, gratitude, and temperance; it was supposed to bear a charmed life, and it was a crime to offer it violence; in some places it was even an object of worship, and in hieroglyphic language it is the symbol of piety and beneficence; "pious" or "beneficent" is also the meaning of its name in Hebrew (*'hasidah*). The black stork (*C. nigra*, Bechst.) is about $2\frac{3}{4}$ ft. long, with a bill of $5\frac{1}{2}$ in.; the color above is black with green and purplish gloss, and white below. It avoids the vicinity of man, nests in trees, and feeds like the herons chiefly on fish; it is found in many countries of Europe, especially in the Alps. The American stork (*C. Americana*, Briss.) is about as large as the white species; it is found in South America, particularly in Brazil.

**STORMONT,** an E. county of Ontario, Canada, bounded S. E. by the St. Lawrence river; area, 409 sq. m.; pop. in 1871, 18,987, of whom 6,229 were of Scotch, 4,191 of Irish, 3,125 of German, 2,233 of French, 1,621 of English, and 1,322 of Dutch origin or descent. It is watered by several small streams, and is traversed by the Grand Trunk railway. Capital, Cornwall.

**STORMS,** violent atmospheric disturbances. (See WIND.) Storm areas are in general characterized by low barometric pressure at their centres; winds increasing in force toward the central region, and by their directions showing the lower portion of the atmosphere to be moving spirally in, toward and around the centre; heavy masses of low clouds attended by a higher stratum that moves around and out from the centre; rain or snow falling especially on the advancing side or front of the storm; temperatures above the average in front, and below the average in the rear of the storm. The storm area with its attending features moves bodily along the earth's surface for several days. A map showing the average number of centres of storms that pass over the eastern portions of the United States is published in the "Statistical Atlas" of the census bureau (1875), and is here reproduced. The number of storm centres passing over any region increases as we go from the lower latitudes toward Hudson bay, being greatest in the region of the St. Lawrence valley and the great lakes. This arises from the fact that while on the one hand many storms move eastward along the northern limits of our field of observation, on the other hand the storms that originate in the lower latitudes tend to move northward. Nine tenths of the storm tracks on which this map is based have moved toward and over New England and Lower Canada. The chart also shows in Nebraska a region of specially numerous storm tracks, from the fact that the storms coming both from Texas and from Dakota frequently move respectively N. E. and S. E. toward this region; and frequently we find here also the first trace of a class of storms that appear to originate on the spot. The peculiarities in the distribution of storms are apparently fully explained by the topography of the continent. When we consider that at any station in the northern hemisphere the winds veer from S. E. to S. W. and N. W. as a storm centre passes N. of it, we perceive from this map that throughout the United States E. of the Rocky mountains the veering of the wind will be more frequent than its backing, in the proportions indicated by the relative number of storm centres that pass to the north and south of the station. For the ocean, it has in general not yet been possible to compile any general map of the average paths of the storms; but from the logs of vessels a great mass of information relative to the frequency of gales and stormy winds has been compiled, and this information is very nearly related to that given by the accompanying chart. The first map of this kind was compiled at the United States naval observatory by M. F. Maury; and the work of collecting such data has been actively pursued by the meteorological officers of all nations, especially England and Holland.—Within 20° of the equator storm winds are exceedingly rare, but their number increases rapidly as we approach the latitude of 50° N. or S. During our northern summer the percentage of storminess diminishes in the North Atlantic and increases in the South Atlantic ocean. In either hemisphere, winter is its stormy season. Within the limits of our observations, viz., up to the parallel of 40° on either side of the equator and in mid-ocean, the southern winter is sensibly as stormy as the northern; but beyond these parallels, and especially near the coast of North and South America, the northern hemisphere is far more stormy than the southern; the probable cause is the greater mass of dry land, and consequently of dry cold air, contiguous to the North Atlantic, as compared with the little land bordering the South Atlantic. Among the regions most frequently passed over by vessels of all nations, the neighborhoods of Cape Horn and the cape of Good Hope are next in importance to the great

UNITED STATES SIGNAL SERVICE CHART,

SHOWING THE

FREQUENCY OF STORM CENTRES

IN THE

Eastern Half of the United States, deduced from the average of the two years, March, 1871, to February, 1873, inclusive.

Note

*This Chart shows the frequency with which the centre of areas of low barometer (assumed to average fifty miles in diameter) have passed over any given district. It does not include local thunder or hail storms.*

UNITED STATES SIGNAL SERVICE CHART,

SHOWING THE

FREQUENCY OF STORM CENTRES

IN THE

Eastern Half of the United States, deduced from the average of the two years, March, 1871, to February, 1873, inclusive.

Note

*This Chart shows the frequency with which the centre of areas of low barometer (assumed to average fifty miles in diameter) have passed over any given district. It does not include local thunder or hail storms.*

highway between Europe and America. The charts of the ocean in the neighborhood of Cape Horn, published by the London meteorological office (1871), do not give the percentages of storms; but for the cape of Good Hope, the charts of Cornelissen (1874), of the meteorological institute of the Netherlands, show that during the southern summer the storms in this region are comparatively few and feeble. In winter severe westerly gales are exceedingly abundant to the south of the cape. In the immediate neighborhood of the continent, and on either side, the influence of the land is shown in the frequency of storm winds blowing off shore during winter, and on shore during summer.—*Storm Warnings.* Suggestions for storm warnings were broached even in the 18th century, before the introduction of the electric telegraph had rendered the undertaking practicable. The Europeans were the first to engage systematically in storm warning; but in the early demonstration of the feasibility of the idea, the merchants and the individual meteorologists of the United States took the lead. If we pass by that which Franklin, Espy, Bache, Redfield, Loomis, Maury, and others did to advance our knowledge of atmospheric phenomena, and consider merely the steps taken to establish national systems of storm warnings, we shall note that in 1835 the joint meteorological committee of the Franklin institute and the American philosophical society at Philadelphia appointed, at the suggestion of Bache and Espy, a sub-committee to memorialize congress upon the subject of a national weather bureau for the study and prediction of storms. When the success of the Morse telegraph was beyond all question, Redfield in 1846, and Loomis in 1847, urged its systematic application to the problem in hand. This idea was greatly furthered by Prof. Joseph Henry, who as secretary of the Smithsonian institution had just removed to Washington. In 1847, in behalf of that institution, he organized a system of volunteer meteorological observations and reports. Through the liberality of the National telegraph line, Prof. Henry was in 1857 able to begin the publication of a telegraphic weather bulletin, and to make successful weather predictions. Meanwhile, the appointment of Espy as meteorologist successively to the war and navy departments, and the publication (1850 and 1857) of his famous reports on meteorology, had awakened a universal conviction that storm predictions were practicable. Already many merchants were habitually obtaining at their own expense weather reports from distant sections. The Smithsonian weather bulletin was of necessity discontinued in 1861, and an effort to revive it in 1864 was frustrated only by a conflagration which destroyed a portion of the Smithsonian building early in the following year. It does not appear that anything more was done in America in the prosecution of the subject of weather predictions until in 1868, in his inaugural report as director of the Cincinnati observatory, the writer proposed this as a work proper for one branch of the institution which he proposed to build up in that city. A few months after this date the Cincinnati chamber of commerce authorized him to obtain at its expense, for three months, the necessary telegrams, and to publish daily weather predictions. This system went into operation on Sept. 1, 1869. In a modified form, and pending further negotiations, the work was continued at the joint expense of the writer and the Western Union telegraph company from December, 1869, to May, 1870, and afterward entirely at the expense of that company, whose manifold weather maps were in much demand until the commencement in November, 1870, of the great work of the army signal office. (See Signal Service.)—Simultaneously with the spread of the telegraph in Europe began the publication of weather bulletins, and their collation and study. Kämtz says that even in 1835 he had begun to study the weather reports in the Berlin papers, but it required the excitement of the Crimean war, in 1854, to force the importance of the subject upon the attention of European governments. In that year Leverrier as director of the Paris observatory took up the subject; his telegraphic reports began in 1855, and his international bulletin in 1858. Weather probabilities were not begun till 1863; these were discontinued in 1865, and only lately have been revived, but storm warning signals have been uninterruptedly displayed since 1860. In 1861 Admiral Fitzroy, of the meteorological department of the board of trade, began the display of storm signals in England, and in the latter part of the year the publication of weather forecasts; his system of warnings consisted rather of a series of signals announcing the presence of storms, than of any real prediction of their advent. The Fitzroy system ceased in 1866, shortly after his death, but was renewed in 1867. Since that time the British ports have regularly received storm warnings, but the display of the storm signal and storm drum was only revived in March, 1875. The French and English systems of storm warnings were in some respects preceded by the system organized in Holland by Buys-Ballot, who in 1854 had announced his famous rule for that country in regard to the direction of the wind, as depending on barometric disturbance. In 1860 he began the communication to the shipping ports of storm warning despatches, and was in fact by his signals the first to utilize the despatches contained in the telegraphic weather bulletins of Leverrier. The organization of the French, English, and Dutch systems suffices to furnish for other European nations such storm predictions as are needed for their respective ports. Thus Spain, Italy, Sweden, Hanover, Russia, Austria, and Turkey receive regularly from Paris and London announcements of the condition of the weath-

er, especially of impending storms. Every nation of the civilized world, including China and Japan, now has national offices for collecting and utilizing meteorological observations. As a general rule, the warning signal, whether it be the drum or cone as in England, or the flags and lights adopted in other countries, is intended to announce merely that the chances are that there will soon be a dangerous high wind in the neighborhood of the station.

**STORRS, Richard Salter**, an American clergyman, born in Braintree, Mass., Aug. 21, 1821. He graduated at Amherst college in 1839, and at Andover theological seminary in 1845, and was ordained pastor of the Harvard Congregational church, Brookline, Mass. In 1846 he became pastor of the church of the Pilgrims, Brooklyn, N. Y., which post he still retains (1876). He was associate editor of the "Independent" newspaper from its commencement in 1848 to 1861. He has published a report on the revision of the English version of the Bible undertaken by the American Bible society; "Graham Lectures, on the Wisdom, Power, and Goodness of God, as manifested in the Constitution of the Human Soul" (New York, 1856); and lectures on "The Conditions of Success in Preaching without Notes" (1875).

**STORY**, a central county of Iowa, intersected by Skunk river; area, 550 sq. m.; pop. in 1870, 11,651. The surface is undulating and the soil fertile. The chief productions in 1870 were 131,022 bushels of wheat, 390,395 of Indian corn, 97,938 of oats, 25,066 of potatoes, 13,730 tons of hay, 8,918 lbs. of wool, 132,249 of butter, and 5,751 gallons of sorghum molasses. There were 1,580 horses, 2,253 milch cows, 4,021 other cattle, 3,185 sheep, and 5,388 swine. The Chicago and Northwestern railroad passes through the capital, Nevada.

**STORY. I. Joseph**, an American jurist, born in Marblehead, Mass., Sept. 18, 1779, died in Cambridge, Sept. 10, 1845. He graduated at Harvard college in 1798, and studied law in Marblehead. In 1801 he removed to Salem and was admitted to the bar. He soon acquired a lucrative practice and the warm friendship of some of the leading federalists, though he was a republican. In 1804 he published a volume of poems containing "The Power of Solitude" and some smaller pieces, but it was not successful. From 1805 to 1808 he was a member of the lower house of the legislature of Massachusetts, and took a very active part as the principal leader on the republican side; but in two of the measures which he espoused, he acted upon purely independent grounds. The first was a bill to increase, and to establish on a permanent basis, the salaries of the justices of the supreme judicial court, which was passed by his exertions in 1807. The other was a bill (1808) to establish a court of chancery for the state; but this did not succeed. In the same year he defended the embargo as the only measure which the administration of Jefferson could have adopted, short of a declaration of war, without submitting to the ignominious restrictions on American commerce by the belligerent powers. He had written in 1806 the celebrated "Memorial of the Inhabitants of Salem relative to the Infringements on the Neutral Trade of the United States," addressed to the president and to congress. In the autumn of 1808 he was elected to congress from the Essex district. In opposition to the administration he exerted himself to procure a repeal of the embargo, upon the ground that he had originally supported it as a temporary measure, and that it had accomplished its real purpose. He left congress before the repeal was consummated, but not before he had largely contributed to bring it about, and Jefferson attributed the repeal almost wholly to his exertions. Declining a reëlection to congress, he was again chosen to a seat in the state legislature in 1810, and in January, 1811, he was elected speaker of the house. On Nov. 18, 1811, he received the appointment of associate justice of the supreme court of the United States; and on Jan. 17, 1812, he resigned the office of speaker. In 1820 he was a member of the convention for the revision of the state constitution. His principal services in that body related to the tenure and the compensation of the judiciary, the apportionment of the house of representatives, and the property basis of the senate. The original constitution contained a clause authorizing the legislature to increase the salaries of the judges of the supreme judicial court. A motion was made and suddenly carried to insert the words "or diminish." The reconsideration and rejection of this amendment were produced by a powerful and brilliant argument by Judge Story, which commanded the assent of more than two thirds of the convention. In 1829 Judge Story was appointed professor of law in Harvard university, on a foundation established by Nathan Dane, for the delivery of lectures on the law of nature, the law of nations, commercial and maritime law, federal law, and federal equity; and for the rest of his life he resided in Cambridge. The law school of which he now became the head immediately attracted students from all parts of the United States. In his constitutional views he was of the school of Washington and Marshall, upholding what he considered as the just powers of the Union, without encroaching upon the rights of the states. His works comprehend "Commentaries on the Constitution of the United States" (3 vols. 8vo, 1833); "Commentaries on the Conflict of Laws" (1834); "Commentaries on Equity Jurisprudence" (2 vols. 8vo, 1836) and "Equity Pleadings" (1838); and treatises on the law of bailments, agency, partnership, bills of exchange, and promissory notes. All of these works have passed through many editions. Judge Story was gifted with great colloquial powers, and his social qualities in private life largely added to the influence of

his learning, talents, and public positions. A life of him by his son, William W. Story, was published at Boston in 1851 (2 vols. 8vo). There is also a collection of his "Miscellaneous Writings" (8vo, 1852). His decisions as a circuit court judge are contained in 13 vols. 8vo, being the reports of Gallison, Mason, Sumner, and Story. His judgments in the supreme court of the United States may be found in the reports of Cranch, Wheaton, Peters, and Howard, from 1811 to 1845. **II. William Wetmore,** an American sculptor and author, son of the preceding, born in Salem, Feb. 12, 1819. He graduated at Harvard college in 1838, and was admitted to the bar in Boston. In 1844 he published a "Treatise on the Law of Contracts," and in 1847 a "Treatise on the Law of Sales of Personal Property." He also published three volumes of "Reports of Cases argued and determined in the Circuit Court of the United States for the First Circuit" (1847). In 1847 he published a small volume of poems; in 1851 a life of his father (2 vols. 8vo); and in 1856 a second volume of poems. Among his subsequent publications are: "Roba di Roma, or Walks and Talks about Rome" (2 vols., London, 1862; New York, 1864; new ed., 1875); "Proportions of the Human Figure" (1866); "Graffiti d'Italia" (Edinburgh, 1869); "A Roman Lawyer in Jerusalem" (1870); and "Nero, an Historical Play" (1875). Since 1848 Mr. Story has resided in Rome, devoting himself to sculpture, for which he early showed a strong inclination. Among his works are a sitting statue of his father, in marble, in the chapel at Mt. Auburn; statues of George Peabody, Josiah Quincy, and Edward Everett; busts of James Russell Lowell and Theodore Parker; and many ideal works of great merit, among which are a "Shepherd Boy," "Little Red Riding-Hood," "Sappho," "Cleopatra," "Jerusalem" (an allegorical female figure representing the desolation of the city after the destruction of the temple), a "Sibyl," and "Semiramis." The last is owned in New York.

**STOTHARD, Thomas,** an English painter, born in London, Aug. 17, 1755, died there, April 27, 1834. At the age of 14 he was apprenticed to a designer of patterns, then became a designer for illustrated books, and studied painting at the royal academy, of which he was elected a member in 1794 and librarian in 1812. He is known by his contributions to "Boydell's Shakespeare," his "Canterbury Pilgrims," the "Flitch of Bacon," the Wellington shield, and his illustrations of Rogers's "Poems" and "Italy." The number of his designs is estimated at 5,000, of which 3,000 have been engraved.—His son Charles Alfred (1786–1821), draughtsman to the society of antiquaries, published a work on the "Monumental Effigies of Great Britain" (13 parts, fol., 1811–'23), in which he was assisted by his wife, afterward Mrs. Bray, and his brother-in-law A. G. Kempe. The former wrote his life and that of his father. (See Bray, Anna Eliza.)

**STOVE.** See Warming and Ventilation.

**STOW, Baron,** an American clergyman, born in Croydon, N. H., June 16, 1801, died in Boston, Dec. 27, 1869. He graduated at Columbian college, D. C., in 1825, and in 1825–'27 edited the "Columbian Star." On Oct. 24, 1827, he was ordained pastor of a Baptist church in Portsmouth, N. H., and in 1832 became pastor of the Baldwin place Baptist church in Boston, and in 1848 of the Rowe street church. He was recording secretary of the board of the general missionary convention from 1838 to 1846. He published "Memoir of Harriet Dow" (1832); "History of the English Baptist Mission to India" (1835); "History of the Danish Mission on the Coast of Coromandel" (1837); "Daily Manna for Christian Pilgrims" (1842); "The Whole Family in Heaven and Earth" (1845); "Question Book of Christian Doctrine" (1848); "The Psalmist," with the Rev. S. F. Smith (1849); "Christian Brotherhood" (1859); and "First Things, or Development of Church Life" (1859). His life has been written by R. H. Neale (Boston, 1870).

**STOW, John,** an English antiquary, born in London in 1525, died April 5, 1605. He was bred a tailor, but from 1560 devoted himself to the study of the antiquities of English history. He made an extensive collection of papers, many of them Catholic records, which occasioned suspicion, and he was cited before an ecclesiastical commission on charges preferred by his own brother, but was acquitted. His works are: a "Summarie of Englysh Chronicles" (12mo, 1561); "Annales, or a Generall Chronicle of England" (4to, 1580); "A Survey of London" (4to, 1598; continued by John Strype, 2 vols., 1720; new eds., 1842 and 1846); and "The Successions of the History of England, from the Beginning of Edward VI. to the End of the Reign of Queen Elizabeth" (1638).

**STOWE. I. Calvin Ellis,** an American clergyman, born at Natick, Mass., April 6, 1802. He graduated at Bowdoin college in 1824, and at Andover theological seminary in 1828, and in 1828–'30 was assistant professor at Andover. In 1830 he became professor of languages in Dartmouth college, and in 1833 of Biblical literature in Lane theological seminary, Cincinnati. In May, 1836, he visited Europe to examine, in behalf of the state of Ohio, the public school system of the German states, and published "Elementary Education in Europe," which was distributed in every district of Ohio by the legislature. He also published reports on the "Education of Immigrants," on "The Course of Instruction in the Primary Schools of Prussia," and on "Elementary Instruction in Prussia." In 1850 he became divinity professor at Bowdoin college, and in 1852 professor of sacred literature in Andover theological seminary. He resigned this office in 1864, and has since resided in Hartford, Conn. His remaining works are: a "History of the Hebrew Commonwealth," translated from the German of Jahn (Andover, 1828; 2

vols., London, 1829); "Lectures on the Sacred Poetry of the Hebrews," from the *Prælectiones* of Lowth, with notes (Andover, 1829); "Introduction to the Criticism and Interpretation of the Bible" (vol. i. only published, Cincinnati, 1835); and "Origin and History of the Books of the Bible" (part i., the New Testament, Hartford, 1867). **II. Harriet Elizabeth Beecher,** wife of the preceding. See BEECHER.

**STOWELL, William Scott,** baron, an English jurist, born in Heworth, Durham, Oct. 17, 1745, died Jan. 28, 1836. He graduated at Oxford in 1764, and was elected a fellow, and soon after a college tutor. In 1774 he became Camden professor of ancient history in the university. In 1779 he was admitted at doctors' commons into the faculty of advocates, and in 1780 was called to the bar. He made a specialty of ecclesiastical and admiralty practice, and within a few years was appointed successively registrar of the court of faculties, judge of the consistory court, vicar general of the archbishop of Canterbury, and advocate general. In 1798 he was made judge of the high court of admiralty, which office he occupied for 30 years. He was elected a member of parliament for Downton in 1790, and was one of the members for the university of Oxford from 1801 to 1821, when he was made a peer. He was a brother of Lord Eldon.

**STRABISMUS.** See SQUINTING.

**STRABO,** a Greek geographer, born at Amasia, in Pontus, Asia Minor, about 54 B. C., died about A. D. 24. He studied rhetoric under Aristodemus at Nysa in Caria; was a pupil at Amisus in Pontus of Tyrannio the grammarian, and at Seleucia in Cilicia of Xenarchus, a peripatetic philosopher. At Alexandria he studied under Boëthus of Sidon, also a peripatetic; and at Tarsus under Athenodorus, a stoic. He travelled in Syria, Egypt, Crete, Greece, and Italy. He wrote "Historical Memoirs," which are lost, and a "Geography." This work, which embodies all the geographical knowledge of the age, is divided into 17 books; the first 2 treat of cosmography, or the description of the earth in general, and the other 15 give accounts of particular countries. Fragments of the 8th and 9th books were discovered in 1875. Among the best editions are those of Casaubon (1597), Kramer (1844–'52), and Meineke (3 vols., 1852; new ed., 1864). There is an English translation by Falconer and Hamilton (3 vols., 1854–'7). (See GEOGRAPHY.)

**STRADELLA, Alessandro,** an Italian musician, born in Naples about 1645, assassinated in Genoa in 1678. He was a singer, violinist, and composer. At Venice he was employed to teach Hortensia, a noble Roman lady of great beauty, with whom a Venetian nobleman was in love. Stradella and Hortensia fell in love and eloped to Rome. Assassins hired by the Venetian found them there, but were so moved by Stradella's music and singing at the church of St. John Lateran, where he was directing the performance of his oratorio "St. John the Baptist," that they informed him of their purpose, and that they had abandoned it. Stradella and Hortensia fled to Turin, where they were favorably received by the duchess regent, and were married. The Venetian hired other assassins, who finally succeeded in wounding Stradella, but he recovered. The next year he and his wife went to Genoa to arrange for the performance of an opera which he had composed at the request of the city. Here other assassins rushed into their chamber and murdered them both. His principal works are the *Oratorio di San Giovanni Battista* and *La forza dell' amor paterno, opera seria* (Genoa, 1678).

**STRADIVARI,** or **Stradivarius, Antonio,** an Italian violin maker, born in Cremona in 1644, died there, Dec. 17, 1737. He was a pupil of Nicolò Amati, and his first violins, made when he was 23 years old, as well as those which he made during the succeeding 20 years, were, in form and style, reproductions of the works of that master. As early as 1668 he began to use a label with his own name, as follows: "Antonius Stradiuarius Cremonensis faciebat, A. D. 16—." For many years the form of his instruments varied; but about 1686 he acquired his peculiar style, which is very manifest in all his subsequent works; although he had three manners and three periods, during one of which, the middle, he produced what is known as the "long" pattern. His productions consist mostly of violins, violas, and violoncellos, though he also made some viols of six and seven strings, as well as mandolins, guitars, and lutes. His instruments are distinguished alike by their external beauty and the superiority of their tone. He was the first to finish his instruments neatly on the inside. He generally selected and cut his wood with great care, and studied the proportions of thickness and breadth most conducive to sonority, the form of the outside line and of the sound holes (in which he attained great elegance), and the lustre and durability of his varnish, and thus produced works that no subsequent maker has been able to rival. So precious are these instruments in the estimation of connoisseurs that the possessors of the finest of them are well known. One, carefully preserved under glass, has never been touched by the bow, and is known as *la pucelle.* The "Dolphin," so called from the richness and variety of the veined wood of its back, formerly belonged to the marquis de la Rosa. The fineness of the wood and the perfection of its form render it the most beautiful work extant of this maker. Others of his famous violins were owned by the late grand duke of Tuscany, M. Allard, Viotti, Artot, and Count Cepol. Several were in the collections of Mr. Goding and Mr. Joseph Gillott in England. Superior specimens command in the market prices ranging from $1,000 to $3,000.

**STRAFFORD,** a S. E. county of New Hampshire, bordering on Maine; area, about 675 sq.

m.; pop. in 1870, 30,243. It has an uneven surface, watered by numerous streams. The soil of the valleys is fertile. Several railroads traverse it. The chief productions in 1870 were 5,122 bushels of wheat, 59,761 of Indian corn, 13,938 of oats, 13,531 of barley, 248,681 of potatoes, 15,752 lbs. of wool, 302,149 of butter, 42,667 of cheese, and 28,903 tons of hay. There were 1,983 horses, 4,227 milch cows, 2,602 working oxen, 3,666 other cattle, 4,627 sheep, and 1,775 swine; 21 manufactories of boots and shoes, 4 of cotton goods, 2 of iron ware, 5 of cotton and woollen machinery, 1 of floor oil cloths, 1 of paper, 1 of sand and emery paper and cloth, 7 of woollen goods, 2 cloth-printing establishments, 2 planing mills, 15 saw mills, 1 flour mill, 3 tanneries, and 1 currying establishment. Capital, Dover.

**STRAFFORD, Thomas Wentworth,** earl of, an English statesman, born in London, April 13, 1593, executed on Tower hill, May 12, 1641. He was educated at Cambridge, travelled abroad, at the age of 21 inherited large family estates, and in 1614 was elected to parliament for the county of York. He was at first a leading member of the opposition, but in 1628 he was created by Charles I. Baron and Viscount Wentworth, joined the court party, and soon became the king's most trusted counsellor. He was appointed lord president of the council of the north, and in 1632 made governor of Ireland. His administration here was severe and unjust. He maintained that Ireland was a conquered country, and treated it as such. His object was to make his master an absolute monarch by means of an executive system which he called "thorough," and he boasted that in Ireland the king was "as absolute as any prince in the whole world." It is generally admitted, however, that the material condition of the people improved under his government, in spite of his despotic measures. In January, 1640, he was created earl of Strafford and appointed lord lieutenant of Ireland. Later in the same year Charles put him in command of the army against the insurgent Scots, before whom the royal troops fled panic-struck, after the rout at Newburn (Aug. 28); and contrary to the strenuous advice of Strafford, the king accepted the terms imposed by the Scots. Dreading the meeting of the parliament which the king at this time, under compulsion, determined to summon, Strafford implored permission to return to Ireland. But Charles, pledging his royal word that "not a hair of his head should be touched by parliament," prevailed upon him to brave the issue. The assembly met on Nov. 3. On the 11th Pym appeared on the part of the commons at the bar of the house of lords, with a message of impeachment. The articles of impeachment accused Strafford of an attempt to subvert the liberties of the country. His guilt is placed beyond a doubt by evidence which has come to light since his death; but it was never proved by his accusers, and his defence, which he conducted himself with great eloquence and ability, was so strong that the house abandoned the original impeachment. A bill of attainder, brought into the lower house, was passed by a great majority. The lords, in a panic, complied; and the bill was sent to Charles for his approval. The king made some endeavors to save him, but apprehended popular violence if he refused a warrant for the execution; and Strafford advised him by letter, for the sake of the public peace, to sacrifice a life which would be resigned cheerfully to a master who had bestowed such "exceeding favors." He moved from his prison to Tower hill with dignity. "I lay down my head," said he, after declaring his innocence, "as cheerfully as ever I did when going to repose." His attainder was reversed under Charles II. His "Letters and Despatches" were edited by Dr. Knowler (2 vols. fol., London, 1739). His life has been written by Elizabeth Cooper (London, 1874).

**STRAITS SETTLEMENTS,** a British colony in Asia, consisting of islands in the strait of Malacca and detached portions of territory adjoining it. It is divided for administrative purposes into three provinces, Singapore, Malacca, and Wellesley, the last including the island of Penang, which will be found described under their own names. The area, and the population according to the census of 1871, are as follows:

| PROVINCES. | Area in sq. m. | Population. |
|---|---|---|
| Singapore | 224 | 97,111 |
| Malacca | 658 | 77,756 |
| Wellesley (mainland) | 236 | 71,433 |
| " (Penang) | 107 | 61,797 |
| Total | 1,225 | 308,097 |

Of the total population in 1871, 200,433 were males and 107,664 females; 103,936 were Chinese, 1,730 Europeans, and the remainder Malays and other East Indians. The Straits Settlements is a crown colony, and is ruled by a governor, resident in Singapore, who is under the direct control of the home government. Subordinate to him are two sub-governors, resident at Malacca and Penang, who have charge respectively of the provinces of Malacca and Wellesley. The colony, which is free commercially, had no public debt in 1871. The gross public revenue in that year was £298,712; expenditure, £266,499. The total value of imports in 1871 was £10,161,563, of which £2,374,106 were from the United Kingdom; of exports, £9,416,642, of which £2,119,732 were to the United Kingdom.—In 1851 the provinces now included in the Straits Settlements, which previously had been subordinate to the presidency of Bengal, were made a dependency of the crown under the governor general of India; and in April, 1867 (by act of Aug. 10, 1866), they were separated from India and created an independent crown colony.

**STRALSUND,** a strongly fortified seaport town of Prussia, in Pomerania, capital of a district of its own name, on the strait which separates the island of Rügen from the mainland, 125 m. N. by W. of Berlin; pop. in 1871, 26,731. The town is situated on an insular site, surrounded by the strait and several ponds, and can only be approached by bridges which connect it with its three suburbs on the mainland. It has a gloomy appearance, but is clean and well paved. The churches of St. Nicholas and St. Mary are fine specimens of the pointed style of architecture. The gymnasium has both a museum and a library. The manufactures include linen and woollen goods, starch, sugar, tobacco, soap, and leather. The town owns nearly 300 vessels, of about 70,000 tons. The chief exports are wheat, malt, timber, wool, and linen. The harbor is large, but shoals prevent vessels drawing more than 15 ft. from entering it.—Stralsund was built by Jaromar I., prince of Rügen, about 1209, and in the 14th century was one of the most important Hanse towns. It successfully resisted a memorable siege by Wallenstein in 1628. The Swedes gained possession of it by the peace of Westphalia, and Frederick William, elector of Brandenburg, captured it from them in 1678, but restored it in 1679. Stralsund surrendered to the Prussian, Danish, and Saxon forces in 1715, but was restored to Sweden in 1720. In 1807 it surrendered to the French, who destroyed part of the fortifications. By the treaty of Kiel in 1814 it was ceded to Denmark, and in 1815 Denmark surrendered it to Prussia.

**STRAMONIUM.** See DATURA.

**STRANGE, Sir Robert,** an English engraver, born in Pomona, one of the Orkney isles, July 14, 1721, died in London, July 5, 1792. While an apprentice in Edinburgh he joined the forces of the young pretender, and after the battle of Culloden took refuge in the highlands. He studied abroad for some years, and in 1751 settled in London as a historical engraver. During a visit to the continent in 1760 he executed many plates after the old masters. He was also a picture dealer, amassed a fortune, and was knighted in 1787. He wrote a "History of the Progress of Engraving," never published. There is a memoir of him by James Dennistoun of Dennistoun (2 vols. 8vo, 1855).

**STRASBURG, or Strassburg** (Fr. *Strasbourg*), a city of Germany, capital of Alsace-Lorraine, formerly of the French department of Bas-Rhin, on the Ill, a tributary of the Rhine, about a mile from the latter river, 90 m. S. S. W. of Frankfort, and 250 m. E. by S. of Paris; pop. in 1876, 94,000, two fifths Protestants. It stands on level ground, is nearly 6 m. in circuit, and is defended by a wall with bastions, ditches, and outworks, and a strong citadel constructed by Vauban. It is entered by seven gates, and the Rhine is crossed by a bridge of boats opposite Kehl. The Ill flows through the town in a N. E. direction, has many branches, and is crossed by several wooden bridges. The streets are generally crooked and narrow, but the principal ones are broad, and there are several fine squares. The houses are well built and rather lofty, with steep roofs. The cathedral, one of the finest Gothic buildings in Europe (see CATHEDRAL), was much damaged during the siege of 1870, but soon restored. It has a famous astronomical clock, constructed by Isaac Habrecht about 1570, one of the greatest works of its kind. Of the other churches the most interesting are those of St. Stephen, St. Thomas, the Temple Neuf, and St. Pierre le Jeune; and there is a fine synagogue. The city library, dating from 1531, was burned in 1870, during the war, with its 200,000 volumes; but

Strasburg Cathedral.

it has since been restored, and in 1874 contained 300,000 and in 1875 350,000 volumes. The university, founded in 1621, was reopened May 1, 1872, by the Germans, and in 1875 had more than 700 students. The military establishments are on an extensive scale. The manufactures include woollen, linen, and cotton goods, sail cloth, jewelry, clocks and watches, cutlery, hardware and cast-iron articles, porcelain, earthenware, soap, leather, straw goods, hosiery, paper, and cards. There are numerous bleach fields, dye works, sugar refineries, breweries, and printing offices; and the town is celebrated for its *pâtés de foie gras.* The trade of Strasburg is extensive, and is greatly facilitated by the navigation of the Rhine.—Strasburg occupies the site of the ancient Ar-

gentoratum, which after the Roman conquest was made a frontier fortress against the Germans. It was a free city of the empire during the middle ages, and was a Protestant city till seized by Louis XIV. in 1681. A Catholic bishopric of Strasburg, however, at the same time ruled a considerable territory on both sides of the Rhine. After about one month's siege and bombardment, the commander, Gen. Uhrich, capitulated to the Germans in the night of Sept. 27-28, 1870; and the city was finally incorporated with the German empire by the treaty of May 10, 1871. The fortifications as well as the town have since been much enlarged.—See Friese, *Vaterländische Geschichte der Stadt Strasburg* (4 vols., Strasburg, 1791-'5); Hermann, *Notices historiques, statistiques et littéraires sur la ville de Strasbourg* (2 vols., 1819); *Documents relatifs au siége de Strasbourg*, by Gen. Uhrich (Paris, 1872); *Geschichte der Belagerung von Strassburg*, by Reinhard Wagner (2 vols., Berlin, 1874); and the account of the siege in vol. ix. of the history of the war published by the German general staff (1875).

**STRATEGOS.** See p. 899.

**STRATFORD,** a town, port of entry, and the capital of Perth co., Ontario, Canada, on the Avon river, at the junction of the Grand Trunk railway with the Buffalo branch, 88 m. W. by S. of Toronto; pop. in 1871, 4,313. It has good water power, and contains manufactories of iron castings, mill machinery, agricultural implements, woollens, steam engines, leather, boots and shoes, &c., and several flouring mills, distilleries, and breweries. The railroad shops are very extensive. There are three branch banks, three weekly (one German) newspapers, a monthly periodical, and Baptist, Congregational, Episcopal, Methodist, Presbyterian, and Roman Catholic churches. The value of imports for the year ending June 30, 1874, was $1,026,038; of exports, $247,244.

**STRATFORD DE REDCLIFFE, Stratford Canning,** viscount, better known as Sir Stratford Canning, an English diplomatist, born in London, Jan. 6, 1788. In 1809 he was appointed secretary of embassy at Constantinople, in 1814 minister plenipotentiary to Switzerland, in 1820 a special commissioner at Washington, and in 1824 at St. Petersburg. He was ambassador to Constantinople from 1825 to 1827, and again from 1841 to 1858; and his diplomatic activity was very conspicuous both during the negotiations which resulted in the intervention of the western powers in favor of Greece, and during the opening period of the Crimean war. He was a warm friend of Reshid Pasha, and many important reforms in Turkey, particularly those affecting the condition of the Christian population, were attributed to his efforts. He was ennobled in 1852. He has published "Why am I a Christian?" (1873), and a play entitled "Alfred the Great in Athelney" (1876).

**STRATFORD-UPON-AVON,** a town of Warwickshire, England, on the right side of the river Avon, 8 m. S. W. of Warwick, and 82 m. N. W. of London; pop. in 1871, 3,863. The town exhibits the architecture of the 16th and

Shakespeare's Birthplace.

17th centuries. Annual fairs are held for the sale of horses, cattle, corn, and cheese. Stratford was a place of some consequence as early as the middle of the 8th century, but derives

Shakespeare's Tomb.

its chief interest now from the fact that it was the birthplace of Shakespeare, his abode in youth and age, and the place of his death and

burial. A part of the ancient house in which he is said to have been born, and which he retained to the time of his death, is still standing in Henley street; it has been purchased for the nation by subscription at a cost of about £4,000, and is as far as possible kept in the same condition as in his lifetime. A church near the river, a handsome cruciform structure with a fine tower and spire, contains his remains and those of his wife, in the vicinity of a monument, the distinguishing feature of which is the celebrated portrait bust of Shakespeare in marble. This edifice was thoroughly restored in 1840. The grammar school, in which, according to tradition, the great dramatist was educated, is established in the upper part of the ancient guildhall. In 1769 a Shakespeare "jubilee" was celebrated in Stratford under the direction of Garrick, on which occasion the present town hall, which contains a statue of the poet, was erected. The tercentenary of Shakespeare's birth was celebrated here, April 23, 1864.

**STRAUBING**, a town of Bavaria, in the district of Lower Bavaria, on the right bank of the Danube, 25 m. S. E. of Ratisbon; pop. in 1871, 11,150. It is one of the oldest towns of the kingdom. It has an ancient town hall, a Gothic church with fine pictures, and one with a celebrated monument of Duke Albert II., and a palace where Duke Albert III. resided with his wife Agnes Bernauer. (See BERNAUER.) Straubing has many breweries and tanneries.

**STRAUSS**, the name of four German musicians, father and three sons. JOHANN, the father, was born in Vienna, March 14, 1804, and died there, Sept. 24, 1849. In early life he was a member of Lanner's orchestra, afterward organized a band of his own, gave concerts in the chief cities of Germany, and soon rivalled Lanner as a composer and conductor. The eldest son, JOHANN, born in Vienna in 1825, has been for many years, by appointment of the emperor, music director of the court balls. Before the death of his father he had organized a band, whose playing has created the greatest enthusiasm in the chief capitals of Europe. In 1872 Strauss (without his band) visited the United States, and conducted the orchestra of 1,000 performers in his own compositions at the so-called world's peace jubilee in Boston. Before returning he gave three concerts in New York. Besides nearly 400 compositions of dance music, he has published four operettas which have met with considerable success: *Indigo* (1871), *Der Carneval in Rom* (1873), *Die Fledermaus* (1874), and *Cagliostro* (1875). JOSEF, who was born in Vienna in 1827 and died there in 1870, left nearly 300 compositions of dance music. The youngest brother, EDUARD, is the leader of an orchestra in Vienna, and has published nearly 200 compositions. The published compositions of the four Strausses are about 1,100 in number, all of which, excepting a few marches and the operettas above mentioned, are music for dancing. Between 300 and 400 are waltzes, many of which are classed as the best productions of this kind of music.

**STRAUSS, David Friedrich**, a German theologian, born in Ludwigsburg, Würtemberg, Jan. 27, 1808, died in Berlin, Feb. 9, 1874. He was educated at Blaubeuren and Tübingen, was curate in 1830 and professor at Maulbronn in 1831, and in 1832 became *Repetent* in the theological seminary at Tübingen, where he also lectured on the Hegelian philosophy in the university. His name was unknown when he published *Das Leben Jesu* (2 vols., Tübingen, 1835; translated by Marian Evans, now Mrs. Lewes, 3 vols., London, 1846; new ed., 2 vols., New York, 1860), which was republished by him in 1864, after the appearance of Renan's work on Jesus, under the title *Das Leben Jesu für das deutsche Volk bearbeitet* (latest ed., 1874). Its design is to critically establish for Christianity a mythical instead of a historical basis, to resolve the Gospels into popular legends, and the miracles into significant poetry. It supposes the existence of Jesus, an exemplary and reformatory rabbi of Galilee; that he lived and died an enthusiastic and admired teacher and innovator; that after his death many marvellous incidents concerning him gradually gained currency; that some of these were exaggerations of actual events, and others symbolical forms in which his disciples clothed his doctrines and precepts; that these wonderful narratives were not produced by single persons, but were the spontaneous outgrowth of poetical and philosophical tendencies in the early church, of which, after being circulated orally for about a century, various compilations were written. The second part of the work assigns a new meaning to the New Testament. The career of Christ symbolizes the moral history of mankind. Humanity is God manifest in the flesh, sinless, working miracles, dying, rising, and ascending to heaven. Thus the narrative applies not to an individual, but to the race; the dogmas are true, though the history is false. Strauss was deprived of his position as *Repetent*, and became a teacher at Ludwigsburg, and afterward in Stuttgart. In 1837 he replied to his critics by three volumes of *Streitschriften*, and in 1838 by *Zwei friedliche Blätter*, but subsequently availed himself of the new editions of his work to controvert his opponents. In 1839 he went to Zürich as professor of dogmatics and church history, but was soon dismissed with a pension, and his nomination resulted in the speedy downfall of the local radical government. In 1840 he married the vocalist Agnes Schebest, but was separated from her. In 1848 he was an unsuccessful candidate for the Frankfort parliament, but was elected to the diet at Stuttgart, from which he withdrew in December on account of the unpopularity of his political conservatism. In 1872 he returned to his native town after a long residence at Darmstadt. His other prin-

cipal works are: *Die christliche Glaubenslehre in ihrer geschichtlichen Entwickelung und in ihrem Kampfe mit der modernen Wissenschaft* (2 vols., Tübingen, 1840–'41); *Der Romantiker auf dem Throne der Cäsaren, oder Julian der Abtrünnige* (Mannheim, 1847); *Ulrich von Hutten* (3 vols., 1858–'60; 2d ed., 1871; English translation by Mrs. Sturge, London, 1874); *Voltaire* (1870; 3d ed., 1872); *Krieg und Friede*, his correspondence with Renan on the Franco-German war (1870); and *Der alte und der neue Glaube, ein Bekenntniss* (1872), showing the contrast between liberty of thought and ecclesiastical domination, and adhering to the latest results of scientific investigations and to materialistic views of the universe. This last of his works created a no less profound sensation than his first. Charles Ritter has published a selected French translation of his minor essays, under the title of *Essais d'histoire religieuse et mélanges littéraires*, with an introduction by Renan (Paris, 1872).—See *David Friedrich Strauss in seinem Leben und seinen Schriften geschildert*, by Eduard Zeller (Leipsic, 1874; English translation, London, 1874).

**STRAW**, the stem of cereal grasses. On the farm it is used as fodder, for littering animals, as manure, and for thatching outhouses and stacks of hay and grain. It is much used for mattresses called palliasses (Fr. *paillasse*, from *paille*, straw). It is employed to some extent for ornamental purposes, as for picture frames and baskets for cut flowers. The Japanese use many-colored straws in ornamenting the exterior of cabinets, work-boxes, &c. In the arts the chief uses of straw are for paper making (see PAPER) and for the manufacture of hats and bonnets. The art of plaiting straw and similar materials is very ancient, and is found in various stages of perfection in every quarter of the globe. In Europe it remained in a comparatively rude state down to the end of the 16th century, when it began to attain commercial importance in France and northern Italy. James I. introduced it into England. The Leghorn plait of Tuscany began to acquire a European celebrity late in the 18th century; it is still unsurpassed. In that portion of Italy a peculiar variety of wheat (*triticum turgidum*) is grown solely for the straw, which is distinguished for its slenderness and strength. The seed grain is grown in the Apennines, and the straw crop on the lowlands, for which it is sown very thickly. The plant is cut before maturity, and left on the ground to dry in the sun, and then tied in bundles and stacked. It is afterward spread out on the ground again to be bleached in the sun and dew, and is finally steamed and fumigated with sulphur. In Tuscany the straws are sorted by women, who can instantly by the touch detect the slightest shades of difference in their thickness. In other countries the sorting is done by means of a series of graduated sieves. The Tuscan straw, owing to its fineness, is plaited as it comes from the hands of the sorter; other kinds must be split into splints for fine work. At first the splitting was done with a knife, but it is now done by passing into each straw a wire with several cutting edges, or more expeditiously by drawing the whole straw over a sharp steel comb. As the split straw when plaited presents alternately its inner and outer surface, the work lacks that uniformity of appearance produced by the whole straw. To secure this, the plan was devised, in the plait called the "patent Dunstable," of laying two splints with their inner surfaces together, which also increases its durability. The plaits are of various widths, depending on the number and thickness of the straws. The usual length in Italy is about 50 metres (54 yards), in England 20 yards. In Tuscany the plaits are coiled spirally into a flat, the edges being knit together and held fast by a thread concealed within the fabric; elsewhere they are usually wound around a block of the shape required, the edges overlapping and the successive coils stitched together. The first straw bonnet braided in the United States is said to have been made in 1798 by Miss Betsey Metcalf, of Providence, R. I. Large numbers of women and children were employed at one time in this country in plaiting straw, but now almost all the braid used is imported. Straw hats and bonnets are sewn in the United States almost entirely by the Bosworth straw-sewing machine, on which when run by steam 100 ordinary hats can be made in a day. There are four companies in Massachusetts and one in Connecticut each of which employs about 100 of these machines, and they are also used by several smaller companies. The hats are pressed by another machine, also of American invention, which smooths them ready for trimming at the rate of four a minute. The value of the straw goods manufactured in the United States in 1870, as reported in the census, was $7,282,086, distributed among nine states: California, $60,700; Connecticut, $1,026,000; Massachusetts, $4,869,514; New Jersey, $54,530; New York, $1,006,000; Pennsylvania, $189,242; Rhode Island, $40,000; Vermont, $1,600; Wisconsin, $34,500. The number of men employed was 1,988; women, 12,594; youths under 16, 343. During the year 1874–'5 the value of the product of Massachusetts increased about 25 per cent., while that of most of the other states has remained nearly the same.—In Ecuador, Colombia, and other parts of South and Central America, a straw is obtained from the *Carludovica palmata*, called by the natives *jipijapa* or *portorico*, which is largely used in the manufacture of the hats known as Panama hats, from the principal port of their shipment, cigar cases, &c. The leaves of the plant, which resembles a palm, are gathered before they unfold, and after the ribs and coarser veins have been removed are cut into shreds. These are exposed to the sun for a

day and then tied into a knot and immersed in boiling water until they become white, when they are hung up in the shade and afterward bleached for several days. The straw is then distributed through the districts, especially in Peru, where the manufacture is carried on. Whole colonies of Indians are engaged in this manufacture. The men, women, and children plait the straw upon a block of wood which they hold between their knees, finishing an ordinary hat in two or three days; but the finest hats occupy several months to complete them, and require especial care in the selection of the straw and the plaiting. The best are made in Ecuador.

**STRAWBERRY,** a well known wild and cultivated fruit, the Anglo-Saxon name of which, *streawberige* or *streowberie*, was probably derived from the straw-like stems of the plant or from the berries lying strewn on the ground. The several species belong to the genus *fragaria* (from the ancient Latin name *fraga*), of the rose family; they are stemless perennial herbs, with compound leaves of three obovate, wedge-shaped, coarsely serrate leaflets, and multiply by runners, which are long weak branches, forming a bud at the end which soon develops roots and leaves, and by the decay of the branch connecting it with the parent becomes an independent plant. The flowers are in a cyme at the end of an erect scape, with a five-lobed, spreading, persistent calyx, and as many bractlets alternating, and thus appearing ten-cleft; petals (mostly white) five; stamens numerous; pistils simple, seated upon a convex receptacle, which when the ovaries are ripe is greatly enlarged, becoming pulpy and edible, and is popularly regarded as the fruit; it is really the much altered end of the stem (see Plant), while the true fruits are the small seed-like akenes, the ripened ovaries, which are scattered over its surface or sunk in little depressions. By abortion of the stamens some of the species become more or less diœcious.—The strawberry is found in all temperate parts

Section of Flower and Fruit.

of the northern hemisphere and in the mountains of South America. While Bentham and Hooker state that there are not more than three or four well defined species, a dozen or more have been described, the plants being, even in the wild state, very variable, while the varieties in cultivation resulting from hybridizing, crossing, and sporting are innumerable. Two species are widely distributed throughout the United States, and one is peculiar to the Pacific coast. The Virginian or common wild strawberry (*fragaria Virginiana*) is found from arctic America to Florida, and west to the Rocky mountains. Its leaves are rather thick, smooth on the upper surface, often shining; the hairs silky and appressed; the calyx erect after flowering; fruit mostly globular, with a narrow neck, and the akenes (seeds) sunken in deep pits in the surface of the receptacle. This has been described under many

Alpine Strawberry (Fragaria vesca).

different names, as it varies greatly, and the western forms appear very different from the eastern. The Alpine strawberry (*F. vesca*), the common species of Europe, is indigenous to this country, especially far northward, extending to Oregon and the N. W. coast; it is found throughout Europe and northern and central Asia. It has thin pale green leaves, the upper surface strongly marked by veins; flower stalks longer than the leaves; calyx remaining open after flowering; receptacle conical or elongated, with the akenes attached to the surface, and not as in the preceding sunk in pits. A taller form is known as the wood strawberry. This was the earliest species cultivated, and is mentioned in the street cries of London of over 400 years ago; the garden of the bishop of Ely at Holborn was in 1483 celebrated for its strawberries, a fact alluded to by Shakespeare in "Richard III." A number of varieties of this are cultivated, but they are more popular in Europe than in this country. The Chilian strawberry (*F. Chilensis*, the *F. grandiflora* of some) is found on the Pacific coast from Oregon southward; it is very robust, with leathery, thick leaflets of a dark green, and sometimes silky on both surfaces, or only below; the flowers are larger than in any other species, and the large yellowish white or rose-colored fruit, sometimes as large as a small hen's egg, erect. This was introduced into the south of France in 1712, and many valuable varieties resulted

from hybridizing it with other species. The Indian strawberry (*F. Indica*) is from upper India, and is naturalized in the southern states; it differs so much from the other species that it was formerly placed in a distinct genus (*Duchesnea*); it has yellow flowers, and is a showy house plant, especially for window baskets, but the fruit is dry and tasteless.—Of the cultivated American varieties, some are pistillate only, and must be planted near perfect flowered varieties, in order that they may be fertilized and bear fruit. The present tendency of cultivators is to discard all unisexual kinds. The great step in their improvement was in the production of "Hovey's seedling," raised by C. M. Hovey of Cambridge, Mass., over 40 years ago; it is a nearly pure Virginian, and has not been excelled if equalled in quality; it is a pistillate, and needs careful cultivation. The next great step was in the production of "Wilson's Albany," or "Wilson" as it is generally called, a most hardy and productive variety, with perfect flowers. Besides the above, the leading American varieties are "Agriculturist," "Seth Boyden," "Charles Downing," "Donner's Prolific," "Kentucky," "Nicanor," and "Monarch of the West." Among the European kinds which succeed here on suitable soils are "Triomphe de Gand," "Jucunda," and "La Constante."—The cultivation of the strawberry is now an important branch of horticulture, the fruit being sent to the city markets from great distances, especially by water. In New York city the first supplies come from Georgia and the Carolinas; then Virginia, Maryland, and Delaware send large quantities before the New Jersey season begins; this lasts three or four weeks, and then the later fruit comes from Connecticut and Massachusetts. The culture requires a well fertilized soil; the plants are formed by runners as already described; they may be set in autumn or spring, but the plants must grow one year in place before they give a crop. The method of planting and cultivation varies. In the annual method, the plants are set in rows two feet apart and a foot apart in the rows; one crop is taken and the plants are ploughed under, another field being ready to come into bearing to take its place. Another method is to plant in the same manner, let the plants run, and the next spring, when the spaces or paths between the rows are filled with new plants, to plough out other paths, turning under the old plants and allowing the new ones to bear fruit; if the alternate spaces are well manured, this method may be continued indefinitely. Still another plan is to cut off all runners as they start, and induce the plants to form large clumps or stools; some varieties do better in this manner than others; it is the best plan for gardens, as the plants continue in bearing three or four years. In northern localities the ground is covered with straw or leaves to prevent injury by frequent freezing and thawing, and this is left on until the fruit is picked, to keep it from being soiled. New varieties are produced from seed, from flowers carefully cross-fertilized or not, sown as soon as ripe; the seedlings come up in four or six weeks, and if protected during the winter and transplanted the next spring, they will bear fruit the following year.

**STRAYS.** See ESTRAYS.

**STREET, Alfred Billings**, an American poet, born in Poughkeepsie, N. Y., Dec. 18, 1811. A lawyer by profession, in 1839 he settled in Albany, where for a number of years he was state librarian. He has published "The Burning of Schenectady, and other Poems" (1842); "Drawings and Tintings," poems (1844); collected poems (1846); "Frontenac," his longest poem (1849); "The Council of Revision," containing the vetoes of the council, a history of the courts of New York, and biographical sketches of governors and judges from 1777 to 1821 (8vo, 1860); "Woods and Waters, or the Saranacs and Racket," a description of a tour in the great northern wilderness of New York (1860); "Forest Pictures in the Adirondacks" (1864); and "The Indian Pass" (1869).

**STRELITZ.** See MECKLENBURG.

**STRENGTH OF MATERIALS**, the resistance offered by the materials of construction to change of form or to fracture. 1. The resistance of materials to external forces tending to overcome their cohesion is classified, according to its forms, as follows:

| | |
|---|---|
| Longitudinal. | Compressing, resisting pulling asunder.<br>Tensile, resisting crushing. |
| Transverse.... | Bending, resisting cross breaking.<br>Shearing, resisting cutting across.<br>Torsional, resisting twisting or wrenching. |

Two or more of these forms of resistance are sometimes called into action simultaneously, as in the case of the crank of a steam engine, which tends to break the shaft both by a transverse strain and by torsion. 2. The "ultimate strength" is the maximum resistance offered to rupture. The "proof strength" is a less degree of resistance, which the body may safely offer when tested. The "working load" is some fractional part of the ultimate strength which may be selected as giving perfect safety against anticipated strains for an indefinite period. 3. The "factor of safety" is the ratio of the ultimate strength to the working load. The following are minimum values of this quantity adopted in what is generally considered good practice, under "dead" and "live" loads, and where the latter are liable to be accompanied by heavy shocks:

| MATERIAL. | Dead load. | Live load. | Shock. |
|---|---|---|---|
| Wrought iron............ | 3 | 5 | 8 |
| Steel.................... | 3 | 6 | 8 |
| Cast iron................ | 4 | 8 | 10 |
| Timber................... | 4 | 8 | 10 |
| Masonry.................. | 6 | 10 | .. |

4. The proof strength is usually, and should be always, below the elastic limit, *i. e.*, the point at

which set becomes proportional, or nearly so, to the distortion produced by the applied force. It is generally about one half or one third the ultimate strength. 5. Tensile resistance, or tenacity, is determined by experiment for each material. The ultimate strength or breaking load of any piece is measured by the product of the area of fractured section into the tenacity of the material of which it is composed; *i. e.*, $P=TK$, and $K=\frac{P}{T}$, where P represents the breaking force, T the tenacity of the material, and K the area of section. Values of T are given in the accompanying table of coefficients of resistance. The very best grades should have values 20 per cent. higher. P and T are taken in pounds upon the square inch. 6. When thin cylinders are exposed to internal pressure, as in steam boilers, steam cylinders, &c., the bursting pressure may be determined by multiplying the thickness of the shell by the tenacity of the material, as given above, and dividing by the semi-diameter. To ascertain the thickness, the pressure and the diameter of the cylinder being given, multiply the pressure by the semi-diameter, and divide by the tenacity of the material as given in the table; or $P=\frac{Tt}{r}$, and $t=\frac{Pr}{T}$, where $P$ = pressure, $t$ = thickness, $T$ = tenacity, and $r$ = radius of the cylinder. If $d$ = diameter, $P=2\frac{Tt}{d}$, and $t=\frac{Pd}{2T}$. Where the joints are double-riveted, the strength at the joints is usually about 0·7 that of the solid plate; single-riveted joints have 0·56 the strength of a solid plate. The mean strength of single-riveted boilers, where the joints are properly shifted, or "broken," is nearly or quite five eighths that of solid plate. A sphere will bear twice as much internal pressure as a cylinder of the same diameter. A thick cylinder is not as strong relatively as a thin cylinder of the same material, and no cylinder, however thick, can withstand an internal pressure exceeding its limit of tenacity, T, as given above. The rule for calculating the strength of a thick cylinder is expressed algebraically thus: $P=T\frac{R^2-r^2}{R^2+r^2}$, and $\frac{R}{r}=\sqrt{\left(\frac{T+P}{T-P}\right)}$, where $r$ = internal radius, $R$ = the external radius, and other values as before. For thick spheres, $P=T\frac{2R^3-2r^3}{R^3+2r^3}$, and $\frac{R}{r}=\sqrt[3]{\left(\frac{2T+2P}{2T-P}\right)}$. 7. The stayed surfaces are usually the strongest parts of a steam boiler. The following formula gives the proper distance between stays, where $t$ = thickness of plate, $P$ = the pressure in pounds per square inch, and $F$ = the factor of safety: $d=\frac{365t}{5FP}$. $P=F\left(\frac{365t}{d}\right)^2$. 8. Bolts, rivets, and lugs are usually exposed to shearing strain. The resistances to shearing of the most commonly used materials are to be taken as equal to the tensile strength. Where shearing is to be resisted, the parts should be fitted with great care, to avoid the possibility of cutting, and to insure that all parts of the cross section attacked shall resist the shearing force as nearly as possible together. Where a pin is fitted but not forced into its socket, the resistance to shearing is taken as three fourths of that due the section exposed to rupture. 9. Crushing is resisted by any given material with a force that varies very greatly with the form given it. Very short columns or compact masses resist very high crushing strains, in consequence of the resistance offered by their particles to dispersion, as well as by their cohesion. Tall columns first bend and then break under a comparatively slight force. The figures in column C of the table give the resistance to crushing when bending does not occur. Seasoned timber has nearly twice as great resistance to crushing as green. Steel should not be used under pressure exceeding its compressive elasticity, which, in tool steel, is about 50,000 lbs. to the square inch. Wrought iron should not be used under pressure exceeding 25,000 lbs. to the square inch. 10. For tall columns, the following formulas were proposed by Prof. Eaton Hodgkinson:

| MATERIALS. | Rounded ends. | Flat ends. |
|---|---|---|
| Solid cylindrical cast-iron columns......... | $W=14{\cdot}9\frac{D^{3\cdot76}}{L^{1\cdot7}}$ | $W=44{\cdot}2\frac{D^{3\cdot55}}{L^{1\cdot7}}$ |
| Hollow cylindrical cast-iron columns...... | $W=13\frac{D^{3\cdot76}-d^{3\cdot76}}{L^{1\cdot7}}$ | $W=44{\cdot}3\frac{D^{3\cdot55}-d^{3\cdot55}}{L^{1\cdot7}}$ |
| Solid cylindrical wrought-iron columns...... | $W=42\frac{D^{3\cdot76}}{L^2}$ | $W=133{\cdot}7\frac{D^{3\cdot55}}{L^2}$ |
| Solid square pillar of Dantzic oak.......... | .................... | $W=10{\cdot}9\frac{D^4}{L^2}$ |
| Solid square pillar of red pine.......... | .................... | $W=7{\cdot}8\frac{D^4}{L^2}$ |

In these formulas $W$ = crushing weight in tons, $D$ = outside diameter in inches, $d$ = inside diameter in inches, $L$ = length in feet, and $D < {\cdot}4L$; *i. e.*, the columns are more than 30 diameters in length. Prof. Rankine gives $P=\frac{fS}{1+a\frac{l^2}{D^2}}$ for tall columns. $P$ = crushing load in pounds; $S$ = sectional area in square inches; $l$ = length and $D$ = external diameter, both being in the same units of measure, whether feet or inches. The following are the values of $f$ and $a$:

| MATERIALS. | Value of $f$. | Value of $a$. | Forms of column. |
|---|---|---|---|
| Cast iron.......... | 80,000 | $\frac{1}{400}$ | Hollow cylinder. |
| Wrought iron..... | 36,000 | $\frac{1}{3000}$ | Solid rectangle. |
| " " ..... | 36,000 | $\frac{1}{6000}$ | Thin square tube. |
| " " ..... | 36,000 | $\frac{1}{2250}$ | Solid cylinder. |
| " " ..... | 36,000 | $\frac{1}{4500}$ | Thin cylinder. |
| " " ..... | 36,000 | $\frac{1}{1500}$ | Angle iron. |
| " " ..... | 36,000 | $\frac{1}{1500}$ | + shaped. |
| Best American wrought iron... | 50,000 | .... | For all shapes. |
| Timber.......... | 6,500 | $\frac{1}{250}$ · | Solid rectangle. |

This formula is frequently designated as Gordon's, having been deduced by Gordon from Hodgkinson's experiments. Multiply the value of $a$, as given in the table, by 4 for columns rounded or jointed at both ends, and by 2 where fixed at one end, rounded at the other. Connecting rods of steam engines are calculated as pillars rounded at both ends. Piston and pump rods are considered as fixed at one end, free at the other. 11. The collapsing of boiler flues was made the subject of a series of experiments by Mr. Fairbairn, and the following formula was deduced: $P = 806{,}000\,\frac{t^{2\cdot19}}{Ld}$, where $P$ = collapsing pressure in pounds per square inch, $t$ = thickness of iron in flues, $L$ = length of flue in feet, and $d$ = its diameter in inches. When the flue is strengthened by angle-iron rings, as is sometimes done with long flues, L is taken as the distance between the rings. This formula has not been verified for short flues of great diameter, or for exceptional proportions. A slight deviation from a truly cylindrical form considerably reduces the strength of the flues; $t^2$ is generally taken instead of $t^{2\cdot19}$. Elliptical flues, having a major diameter $a$ and a minor diameter $b$, are of equal strength with a cylindrical flue of the diameter $2\frac{a^2}{b}$. 12. The transverse strength of beams may be calculated by the following formulas:

$W=\frac{Kbd^2}{L}$ and $W=\frac{KAd}{L}$ for beams fixed at one end and loaded at the other.

$W=2\frac{Kbd^2}{L}$ and $W=2\frac{KAd}{L}$, where fixed at one end and uniformly loaded.

$W=4\frac{Kbd^2}{L}$ and $W=4\frac{KAd}{L}$, where supported at both ends and loaded at centre.

$W=8\frac{Kbd^2}{L}$ and $W=8\frac{KAd}{L}$, where fixed at both ends and loaded at centre.

$W=8\frac{Kbd^2}{L}$ and $W=8\frac{KAd}{L}$, where supported at both ends and uniformly loaded.

$W=12\frac{Kbd^2}{L}$ and $W=12\frac{KAd}{L}$, where fixed at both ends and uniformly loaded.

Here $W$ = breaking weight in pounds, $K$ = a coefficient which varies with every change in form of cross section of the beams, $d$ = depth of beam in inches, $b$ = breadth in inches, $A$ = area of cross section of the beam at point of rupture in square inches, and $L$ = length between supports in feet. The values of K given in the table, where the beams are of rectangular section, fixed at one end and loaded at the other, are obtained from various sources. 13. For other than rectangular sections the following may be taken as the values of K for cast iron: Shape, ; value, K = 500. Shape, , equal flanges; value, K = 520. Fairbairn, ; value, K = 580. Hodgkinson, ; value, K = 850. The following values are given for wrought iron: rolled rails, , 600; Fairbairn's riveted beam, , 900; box beam, , 1,000. 14. For the wrought-iron beam, when supported at both ends and uniformly loaded, the formula $W=\frac{8D\left(a+\frac{a'}{6}\right)S}{L}$ is used by some American manufacturers. $D$ = depth in feet; $a$ = area of flange in inches, $a$ = that of "stem" or web; $S$ = stress per square inch of area, $a+\frac{a'}{6}$, in tons. The deflection, $S=\frac{.006WL^3}{\left(a+\frac{a'}{6}\right)d^2}$, where the load is applied at the middle, and $S'=\frac{.004WL^3}{\left(a+\frac{a'}{6}\right)d^2}$ when applied uniformly. The depth D is measured between the centres of gravity of the flanges. In such beams it is customary to allow as maxima 10,000 lbs. per square inch in tension and 6,000 to 8,000 in compression. Deflection should not exceed $\frac{1}{30}$ of an inch per foot of length, in any structure. 15. Torsional strength is computed by the formula $W = S'\frac{D^3}{R}$; $D = \sqrt[3]{\frac{WR}{S'}}$; where $W$ = breaking weight in pounds, $D$ = diameter of shaft in inches, and $R$ = length of lever arm in feet. The coefficient $S'$ is very nearly proportional to the tenacity of the material, where the torsion is equal in degree. 16. Resilience is a term introduced by Dr. Young. It is measured by the amount of work performed in producing the maximum strain which a given body is capable of sustaining, and is the quality of primary importance where shocks are to be sustained. Mallet's coefficient of resilience is the half product of the maximum resistance into the maximum extension. But for tough metals it is equal approximately to two thirds the product of the ultimate strength of the material by the distance through which the body yields before the straining force. For very brittle materials it is measured by half that product. No material can resist the shock of a body in motion, unless it is capable of offering resilience equal to the amount of work performed in setting that body in motion at the given velocity; *i. e.*, equal to the amount of energy stored in the moving mass at the instant of striking. In predicting the effect of shock, therefore, it becomes necessary to know the amount of energy stored in the moving body and the resilience of the resisting material. To meet a violent shock successfully, resilience, rather than mere strength, must be secured. As an instance, it is found that wrought iron of comparatively low tenacity but great toughness, capable of stretching considerably before fracture, is far superior to steel for armor for iron-clad ships; the latter has much greater strength, but also greater brittleness. Such calculations are not usually made in designing. Immunity from the injurious effect of shock is

secured by the use of a large factor of safety in proportioning parts exposed to them, by care during construction in the selection of tough resilient materials, and in management by carefully adjusting all parts, and applying the load so as to avoid jarring action as far as possible. 17. If a weight, acting as a steady load, produces a given deflection or change of dimensions, it will require but half that weight suddenly applied to produce a similar effect, whether it be fracture or a stated alteration of form. The extension of ordinary wrought iron within its limit of elasticity is about ·0001 per ton per square inch of section. The amount of extension before fracture by tension is given, with the finest quality of wrought iron, at 20 per cent., with medium quality 16 per cent., and it runs in some irons as low as 4 per cent. Cast iron of fair quality is elongated but a fraction of 1 per cent. 18. The extension of steel varies with the amount of carbon, and nearly inversely as its tenacity. The following table is taken in part from Trautwine's "Engineer's Pocket Book:"

ULTIMATE TENSILE STRENGTH IN POUNDS PER SQ. IN., AND ELONGATION IN INCHES, BEFORE BREAKING.

NOTE.—The specimens tested were steel bars of different grades made from pure Swedish iron, and each bar was turned to a diameter of one inch for a length of 14 inches.

| SPECIMENS. | Per cent. of carbon. | Breaking weight. | Elongation. | Resilience. |

In the larger table, the ultimate resilience of metals is given as tested in the Stevens institute of technology, Hoboken, N. J. Phosphor bronze considerably exceeds ordinary bronze in ductility and resilience. 19. Heating wrought iron within certain limits, and then cooling under stress, increases its strength by relieving internal strain. Cold rolling and wire-drawing increase it, in some cases, 100 per cent. Mr. Dean of Boston and Uchatius of Vienna have similarly increased the strength and elasticity of bronze. Overheating, annealing, and cold hammering decrease its strength. Cast iron of open structure and low density is increased in strength by successive remeltings, sometimes to the amount of 100 per cent., over pig metal. Casting under a head, or under considerable pressure, similarly benefits both cast iron and cast steel. Sir Joseph Whitworth produced a steel of extraordinary strength and toughness by casting under heavy pressure. The internal strain consequent upon sudden cooling, or upon cooling awkwardly shaped castings, seriously reduces their strength and sometimes produces actual fracture. The character of cast iron is largely determined by its density, 7·2 to 7·3 representing the best limits for ordinary practice. Cold wrought iron is more than twice as strong as red-hot. Strength, ductility, and resilience increase with diminishing temperatures, when the materials are of good quality. Cold-blast cast iron is usually stronger than hot-blast iron made from the same ores. Copper loses 25 per cent. of its tenacity at 550° F., 50 per cent. at 810°, and 67 per cent. at 1,000°, the diminution of tenacity varying nearly as the square root of the third power of the temperature. Metals in large masses have usually less density and strength than when worked into sheets, bars, or wire. Wrought iron is particularly liable to loss of strength in large forgings. Bars two inches in diameter being made of the same metal as other bars one inch in diameter, the latter are sometimes found to have 20 per cent. more strength. Steel exhibits even greater differences. 20. Indentation is resisted by wrought iron nearly in proportion to its thickness. Fairbairn found the force necessary to push a blunt point or a ball 3 in. in diameter through boiler plate, one quarter of an inch thick, to be 17,000 lbs., and nearly equal to that required to drive the same instrument through a three-inch oak plank. Resistance of armor plate to penetration by shot varies, if the plate be well backed, as the square of thickness, within the limit of moderate thickness. The material should be strong and ductile. 21. Generally, in designing machines or parts of machines, they should be so proportioned that all parts will have factors of safety of nearly equal value. Economy of material is thus secured, and also the very important advantage, where exposed to severe shock or sudden strains, of utilizing the resilience of the whole machine in resisting them. Forms of uniform strength should therefore be used wherever possible. Suspension rods of uniform strength must have a greater section at the point of support than at the point of attachment of the load, as the upper portions carry not only the load but the weight of the lower part of the rod. Pump rods and wire ropes for deep mines are for this reason made tapering, with the largest section at the top. Care should always be taken that the pieces connected and their fastenings are, when possible, equally strong. Tall columns are slightly swollen at the middle portion in order that they may be equally liable to break at all points, and the Hodgkinson form of cast-iron beams, and the Fairbairn (I) form of section of wrought-iron beams, are given their peculiar shapes in order that no surplus material may exist in either top or bottom flange. Beams of uniform strength, when fixed at one end and loaded at the other, if of uniform depth, are triangular in plan. If uniformly loaded, they represent in plan a pair of parabolas whose vertices touch at the outer end. When of uniform breadth, their vertical sections are parabolic in the first

case, and triangular in the second. Beams of uniform depth, supported at the ends and loaded at the middle point, are in plan a pair of triangles with a common base at the load. If uniformly loaded, the plan is a pair of parabolas with their bases at the middle of the beam. When supported at the ends and uniform in breadth, they are in vertical section a pair of parabolas, in the first case with vertices at the ends and bases meeting at the load, and in the last case semi-ellipses extending between the points of support. In building bridge girders, economy of material is secured by the use of isosceles bracing set at angles of 45°. In vertical and diagonal bracing, the proper angle for diagonals is 55° measured between the diagonal and the vertical. The amount of resistance of a cylinder to rupture by torsion is nearly double that to breaking across. Bolts exposed to shocks and sudden strains, as when used as armor-plate fastenings, are found to resist much more effectually where resilience is secured by turning down the shank to the diameter of the bolt at the bottom of the thread, or otherwise creating a uniform area of section between head and nut. Punching rivet holes weakens plates of hard iron and steel. The latter are injured so seriously that steel plates are never punched by careful engineers. (See STEEL.) In hard iron the reduction of strength is often considerable (15 per cent. as shown by some experimenters); and in many cases, in boiler work, for this reason, the rivet holes are all drilled, notwithstanding the increased cost. Where the iron is very soft and ductile, punching produces less injury. 22. Elasticity is that quality by the possession of which the strain, or distortion of form, produced in any body by stress, is wholly or partially removed on the removal of the stress. All bodies have more or less elasticity, and, when perfectly homogeneous and free from internal strain, are perfectly elastic within a certain limit, which is called the limit of elasticity. Within this limit, the displacement produced by any force is directly proportional to that force. Beyond the limit of elasticity, the strain produced by stress is not wholly removed on the cessation of the stress. The permanent change of form so produced is called the "set." This set takes place on the application of the slightest force where the material is not uniform in character and free from internal strain. Hodgkinson found that in iron, far within the elastic limit, the lightest loads produced slight set. Beyond the elastic limit the set becomes nearly proportional to the distortion, the resistance also increasing up to the point at which rupture begins, but in a far higher ratio. Repeatedly straining a piece beyond its elastic limit produces "fatigue" and ultimate fracture. This may occur by the application of force far less than that producing immediate rupture. 23. The modulus of elasticity, sometimes called the coefficient of elasticity, is the quotient obtained by dividing the measure of the force producing distortion by the measure of the distortion produced by it. Its value varies with every material. The ordinary values of the modulus are given in the table. These values, as is proved by autographic strain diagrams, are liable to variation, within very wide limits, by every circumstance which affects the physical character of the materials. It has no fixed relation to the ultimate strength. It will be seen that this quantity may be defined as the measure of that force which, supposing no limit to elasticity, would shorten or lengthen a bar, originally a unit in length, to the extent of one unit. Thus, a bar of ordinary forged iron, one foot long, would be altered in length $\frac{1}{10,000}$ by a force equal to $\frac{25,000,000}{10,000} = 2500$ lbs. per square inch of section. 24. *Testing Machines.* The strength of materials is determined by means of testing machines. 25. Fig. 1 represents a machine for determining longitudinal resistance, as built by the Messrs. Riehlé of Philadelphia. It consists of a weigh-beam, accurately made and

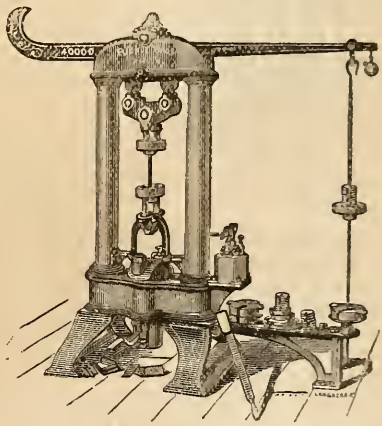

FIG. 1.—Riehlé's Longitudinal Testing Machine.

nicely poised upon knife edges. At its outer end it sustains a scale pan upon which weights measuring 2,000 or 4,000 lbs. are placed. Intermediate weights are measured by a poise, not shown in the figure, which traverses the beam, the latter being divided into parts of 10 lbs. each, similarly to the steelyard balance. The specimen is secured at the upper end by wedges or clamps, in a strong collar which is hung from two knife edges, one on each side the knife edge carrying the scale beam. These knife edges are placed at slightly different distances from the knife edge supporting the beam, thus making the latter a "differential lever," and permitting the measurement of a very great force without compelling the use either of large weights or of a series of levers. A similar collar below takes the lower end of the specimen to be tested. This second collar is secured to the head of a hydraulic press which is placed within the lower part of the frame of the machine. A small pump, worked

by a hand lever, is used to force oil into the press. The breaking force is thus applied from below, and is measured upon the lever above. 26. With the autographic recording testing machine of Prof. R. H. Thurston, fig. 2, nearly all of the essential qualities as well as the strength of materials are determined by the automatic production of a strain diagram. This diagram is an exact graphical representation of all circumstances attending the distortion and fracture of the specimen. No system of personal observation yields results as trustworthy or with such precision as an autographic registry. No other method gives simultaneously, and at every instant during the test, the intensity of the distorting force and the magnitude of the coincident distortion. In this machine two strong wrenches are carried by the A frames, and depend from axes which are both in the same line, but which are not connected with each other. The arm of one of these wrenches carries a weight at its lower end. The other arm is designed to be moved by hand in the smaller machines and by a worm gear in larger ones. The heads of the wrenches are fitted to take the head on the end of the test pieces, which are usually given the form shown in fig. 3. A guide curve of such form that its ordinates are precisely proportional to the torsional moments exerted by the weighted arm while moving up an arc to which the corresponding abscissas of the curve are proportional, is secured to the frame next the weighted arm. The pencil holder is carried on this arm, and as the latter is forced out of the vertical position, the pencil is pushed forward by the guide curve, its movement being thus made proportional to the force which, transmitted through the test piece, produces deflection of the weighted arm. The guide curve is a curve of sines. The other arm carries the cylinder upon which the paper receiving the record is clamped, and the pencil makes its mark on the table thus provided. This table having a motion, relatively to the pencil, which is precisely the angular relative motion of the two extremities of the test piece, the curve described upon the paper is always of such form that the abscissa of any point measures the amount of the distortion which the force produces. 27. The vertical scale of the diagrams produced is a scale of torsional moments, and the horizontal scale is one of total angles of torsion. Since the resistance to shearing, in a homogeneous material, varies with the resistance to longitudinal stress, the vertical scale is also for such materials a scale of direct resistance; and with approximately homogeneous substances this scale is approximately accurate, where, as here, all specimens compared are of the same dimensions. 28. By fig. 4 it will be seen that the first portion of the line rises at a slight inclination from the vertical, and very nearly straight. The amount of distortion here is seen to be approximately proportional to the distorting force, illustrating Hooke's law, *Ut tensio sic vis.* After a degree of distortion which is determined by the specific character of each piece, the line becomes curved, the change of form having a rate of increase which varies more rapidly than the applied force. When this change begins, the molecules, which up to that point retain generally their original distribution, while varying their relative distances, begin to change their positions with respect to each other, moving upon each other in a manner similar to that action described by H. Tresca, and called the "flow of solids." This point, at which the line begins to become concave toward the base, is considered as marking the torsional limit of elasticity. It is well defined in experiments upon woods; is less marked, but still well defined, in the fibrous irons and the less homogeneous specimens of other metals; and becomes quite indeterminable with the most homogeneous materials, as with the best qualities of well worked cast steel. This point does not indicate the first set, since a set occurs with every degree of distortion, however small. It is at this elastic limit that the sets begin to become proportional to the degree of distortion. The inclination of the straight portion of the line from the vertical measures the stiffness of the specimen. This rigidity is very closely, if not precisely, proportional to the hardness, in homogeneous substances; and this quantity is taken, for practical purposes, as a measure of the hardness of the metals and of their elastic resistance to compression. After passing the elastic limit, the line becomes more and more nearly parallel to the base line, and then, with the woods invariably, and in some cases with the metals, begins to fall before fracture becomes evident in the specimen. With the more ductile substances, nearly all the particles are brought up to a maximum in resistance before fracture occurs, and this circumstance has an important influence in deter-

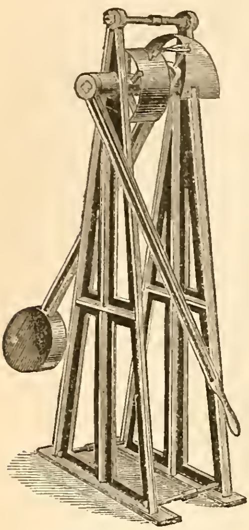

FIG. 2.—Thurston's Testing Machine.

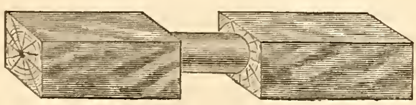

FIG. 3.—Test Piece.

mining the resistance to rupture. The hardest and most brittle materials break with a snap before any flow is perceptible, before the line of the diagram begins to deviate from the direction taken at the commencement, and before the approach to the elastic limit is indicated. The elasticity of the material is determined by relaxing the distorting force, and allowing the specimen to relieve itself from distortion so far as its elasticity will permit. In such cases, the pencil traces a line *e*, O, resembling, in its general form and position in respect to the coördinates, that forming the initial portion of the diagram, but almost absolutely straight, and more nearly vertical. The degree of inclination of this line indicates the elasticity, precisely as the initial straight line gives a measure of the original stiffness of the test piece. The homogeneity of the material tested is hardly less important than its strength. The degree of depression of the line immediately after passing the elastic limit exhibits the greater or less homogeneousness of the material. The resilience of the specimen is measured by the area included within the curve, this being the product of the mean force exerted into the distance through which it acts in producing rupture; *i. e.*, it is proportional to the work done by the test piece in resisting fracture, and, taken up to the ordinate of the limit of elasticity, measures the capacity for resisting shock without serious distortion or injurious set. The ductility of the specimen is deduced from the value of the total angle of torsion, and its measure is the elongation of a line of surface particles, originally parallel to the axis, which line assumes a helical form as the test piece yields, and finally parts at or near the point where the maximum resistance is observed. 29. The strain diagrams exhibit the characteristic differences of various materials. The woods have a structure which differs in a distinguishing degree, both in the distribution of the substance and in the action of those molecular forces capable of resisting rupture, from that of the metals, the latter being far more homogeneous than the former. Wood consists of an aggregation of strong fibres, lying parallel, or approximately so, and held together often by a comparatively feeble force of lateral cohesion. The metals, on the other hand, are naturally homogeneous, both in structure and in the distribution and intensity of the molecular forces. Well worked and thoroughly annealed cast steel, as an example, is equally strong in all directions, is perfectly uniform in its structural character, and is almost absolutely homogeneous as to strain. Wrought iron, as usually made, has a somewhat fibrous structure, which is produced by particles of cinder originally left in the mass by the imperfect work of the puddler while forming the ball of sponge in his furnace, which, not having been removed by the squeezers or by hammering the puddle ball, are, by the process of rolling, drawn out into long lines of non-cohering matter, and produce an effect upon the mass of metal which makes its behavior under stress somewhat similar to that of the stronger and more thready kinds of wood. In the low steels also, in which, in consequence of the deficiency of manganese accompanying almost of necessity their low proportion of carbon, this fibrous structure is produced by cells and bubble holes in the ingot, refusing to weld up in working, and drawing out into long microscopic, or less than microscopic, capillary openings. In consequence of this structure, a depression indicating this heterogeneousness of structure interrupts the regularity of their curves, immediately after passing the limit of elasticity. 30. The presence of internal strain constitutes an essential peculiarity of the metals which distinguishes them from organic materials. The latter are built up by the action of molecular forces, and their particles assume naturally and invariably positions of equilibrium as to strain. The same is true of all naturally formed organic substances. The metals, however, are given form by external and artificially produced forces. Their molecules are compelled to assume certain relative positions, and these positions may be those of equilibrium, or they may be such as to strain the cohesive forces to their very limit. This peculiar condition is of serious importance where the metal is brittle, as is illustrated by the behavior of cast iron, and particularly in ordnance. Even in ductile metals, it produces a reduction in the power of the material to resist external forces. This condition of internal strain may be relieved by annealing hammered and rolled metals, and by cooling castings very slowly, so that the particles may naturally assume positions of equilibrium. In tough and ductile metals, internal strain may be removed by heating to a high temperature and then cooling under the action of a force approximately equal to the elastic resistance of the substance. This process, called "thermo-tension," was first used by Prof. W. R. Johnson in 1836. The cause of this, which he terms an anomalous condition of the metal, was not then discovered. Ductile metals may be strengthened in a considerable degree by this relief of internal strain, and also by simply straining them while cold to the elastic limit, and thus dragging all their particles into extreme positions of tension, from which when released from strain they may all spring back into their natural and unstrained positions of equilibrium. This fact was noted by Prof. Thurston, and soon after independently by Commander Beardslee, U. S. N. It has an important bearing upon the resisting power of materials, and upon the character of all formulas in which it may be attempted to embody accurately the law of resistance of such materials to distorting or breaking strain. The initial portion of the diagram, when the material is free from internal strain, is a straight line up to the limit of elasticity. This line, with strained materials, becomes con-

vex toward the base line. The initial portion of the diagram, therefore, determines whether the material tested has been subjected to internal strain, or whether it is homogeneous as to strain. This is exhibited by the direction of this part of the line, as well as by its form. The existence of internal strain causes a loss of stiffness, which is shown by the deviation of this part of the line from the vertical to a degree which becomes observable by comparing its inclination with that of the line of elastic resistance. 31. In fig. 4, the strain diagram A is that of zinc. The concave form at the commencement indicates its inelastic nature, its slight altitude shows its weakness, and, breaking at 65°, it is shown to lack ductility. Tin, T, is vastly more ductile, but is still less tenacious. B and C are the diagrams given by cast and forged copper, the latter twisting 500°, and its fibres stretching to three times their original length. Cast copper is comparatively weak and brittle. Wrought iron gives the strain diagram D. It indicates the elasticity of the metal, its ductility, and its strength. The elastic limit is plainly indicated. The con-

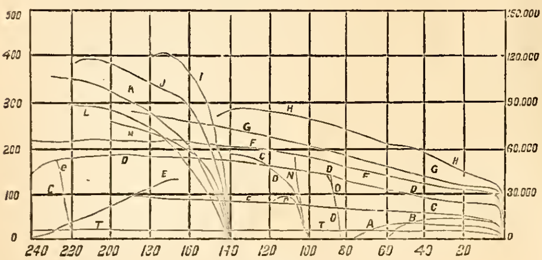

Fig. 4.—Strain Diagrams.

cavity of the initial portion of the line indicates some internal strain, and the horizontal portion immediately above the elastic limit shows that the metal was "seamy" and not perfectly homogeneous. The lines $e$ and O are "elasticity lines." They differ slightly in direction from the initial portion of the diagram, confirming the previously indicated presence of internal strain. E is the terminal portion of the diagram of a soft ductile iron. F is that given by a very strong and ductile and exceptionally homogeneous iron, a very smooth and symmetrical curve. G is a soft Bessemer steel. H is somewhat harder, the one containing 0·4 and the other 0·5 per cent. of carbon. I and J are tool steels containing 1 per cent. of carbon. K is medium, L spring, and M double shear steel. N and P are obtained from white and gray cast iron. One is stiff, hard, and brittle, the other weaker, soft, and comparatively tough. O is a malleableized cast iron made from N; it has lost no strength, and has gained considerable ductility. Strain diagrams may be produced by plotting data obtained by observation in the usual manner and similarly interpreted. 32. An examination of the fracture in each case assists in determining the character of the material, and in interpreting the strain diagram. The following figures exhibit the characteristics of various qualities of iron and steel. Fig. 5 resembles that which gave the diagram marked D. The metal is good and tough, but seamy, and not thoroughly worked, as is shown by the cracks extending around the neck and by the irregularly distributed flaws on its end. Fig. 6 exhibits the appearance of the sample F. The surface of the

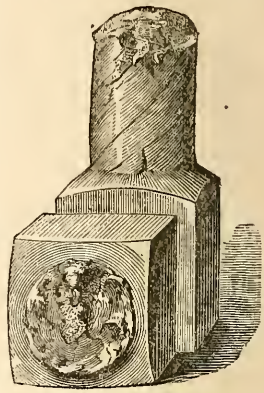

Fig. 5.

neck was originally smoothly turned, polished, and fitted to gauge. Under test it became curiously altered and assumed a rough, striated appearance. The end has the peculiar appearance characteristic of tough and ductile metals, and the uniformly bright appearance of the fractured section shows that all held together up to the instant of rupture, and that fracture finally took place by shearing. Fig. 7 represents the appearance of low steels. The peculiarities of the finest tool steels are exhibited in fig. 8. In this the fracture is ragged and splintery, and the separated surfaces have a beautifully fine, even grain, which proves the excellence of the material. The surface, which was turned and polished in bringing the metal

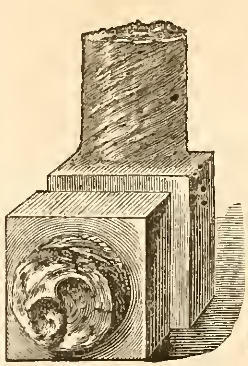

Fig. 6.

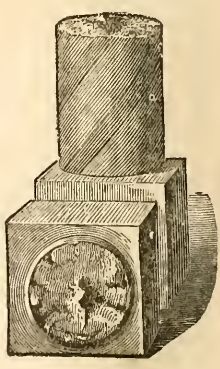

Fig. 7.

to size, remains as perfect as before the specimen was broken. By an inspection of the broken test pieces in this manner, the grade of the steel, and by the practised eye the slightest

possible variations, are readily distinguished. Fig. 9 is white cast iron. Its surface, where fractured, has the general appearance of broken tool steel, but the color and texture of the metal are distinctive; it has none of the "steely grain." Fig. 10 represents dark foundery iron.

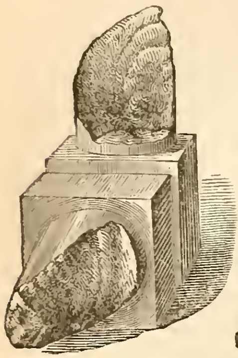

Fig. 8.

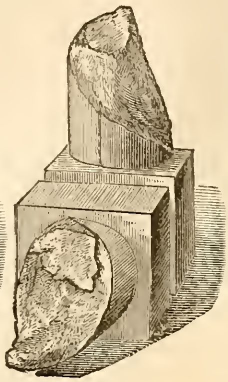

Fig. 9.

Its color, its granular structure, and coarse grain are markedly characteristic. 33. Good iron plates should, in addition to the above tests, be subjected to the following: When red-hot, they should be capable of being bent sharply to a right angle without cracking, up to an inch in thickness. Ordinary boiler plate of good quality should bend double. When cold, they should bend along the grain without cracking, as follows: 1 in. thick, 15°; ¾ in. thick, 25°; ½ in. thick, 35°; ¼ in. thick, 90°. Across the grain they should at least bend half as far. They should be bent on a slab rounded on the corners with a radius of ½ in. Steel plates should be 50 per cent. more ductile.

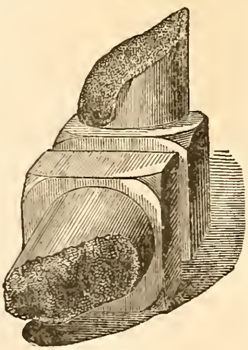

Fig. 10.

34. *Testing within the Limit of Elasticity.* In determining the value of materials of construction, it is usually more necessary to determine the position of the limit of elasticity, and the behavior of the metal within that limit, than to ascertain ultimate strength or resilience. It should be possible to test every piece of material which goes into an important structure, and then to use it with confidence that it has been proved capable of carrying its load with a sufficient and known margin of safety. It is common to test bridge rods to a limit of strain determined by specification, and to compel their rejection when they are found to take a considerable permanent set under that strain. Specification now frequently (and it should invariably) makes the limit of elasticity the basis of calculation and test.—See Fairbairn, "Cast and Wrought Iron" (London, 1865); Haswell, "Engineers' and Mechanics' Pocket Book" (New York, 1868); Trautwine, "Civil Engineers' Pocket Book" (Philadelphia, 1872); Rankine, "Useful Rules and Tables" (London, 1872); Thurston, "Strength, Elasticity, Ductility, and Resilience of Materials of Construction" (Philadelphia, 1874); and Wood, "Resistance of Materials" (New York, 1875).

**STRICKLAND, Agnes,** an English authoress, born at Reydon hall, Suffolk, July 19, 1796, died in London, July 13, 1874. She was carefully educated under the personal supervision of her father. Her works are: "Worcester Field, or the Cavalier," a poem (1812); "Demetrius," a poetical romance (1833); "The Pilgrims of Walsingham," a series of tales (1835); "Alda, the British Captive" (1841); with her sister Elizabeth, "Lives of the Queens of England" (12 vols., 1840–'49; abridged and edited by Caroline G. Parker, 1 vol. 12mo, New York, 1867), and "Lives of the Queens of Scotland" (8 vols., 1850–'59); "Queen Victoria, from her Birth to her Bridal" (2 vols., 1840); "Historic Scenes and Poetic Fancies" (1850); "Old Friends and New Acquaintances" (1850); "Lives of the Bachelor Kings of England" (1861); "How will it End?" a novel (1865); "Lives of the Seven Bishops committed to the Tower in 1688" (1866); and "Lives of the Tudor Princesses" (1868). She edited an edition of the letters of Mary, queen of Scots, and thus brought to public notice many documents of much historic value. In 1871 she received an annual pension of £100. —The sisters of Miss Strickland, Jane Margaret, Catharine Parr (Mrs. Trail), and Susannah (Mrs. Moodie), besides assisting her in her historical works, published several books under their own names. Mrs. Trail and Mrs. Moodie are residents of Canada, and their chief works have been upon life in that country.

**STRICKLAND, William Peter,** an American clergyman, born in Pittsburgh, Pa., Aug. 17, 1809. He was educated at the Ohio university, Athens, O., entered the ministry of the Methodist Episcopal church in 1832, labored several years in Cincinnati, and then became agent of the American Bible society. In 1850 the Ohio university conferred on him the degree of D. D. In 1856 he removed to New York, where he engaged in literary labor, mostly in connection with the Methodist book concern. In 1862 he was chaplain of the 48th New York regiment, stationed at Port Royal, S. C. Since 1866 he has been pastor of the Presbyterian church in Bridgehampton, L. I. His principal publications are: "History of the American Bible Society" (New York, 1849; new ed., with history continued, 1856); "History of Methodist Missions" (1850); "Genius and Mission of Methodism" (1851);

"Christianity Demonstrated" (1852); "Memoir of the Rev. James B. Finley" (1853); "A Manual of Biblical Literature" (1853); "The Light of the Temple" (Cincinnati, 1854); "The Astrologer of Chaldea" (1856); "Pioneers of the West" (New York, 1856); "Life of the Rev. Francis Asbury" (1858); "Life of Jacob Gruber" (1859); and "Old Mackinaw" (Philadelphia, 1860).

**STRINGHAM, Silas Horton**, an American naval officer, born at Middletown, N. Y., Nov. 7, 1798, died in Brooklyn, Feb. 7, 1876. He entered the navy as midshipman in 1809, became lieutenant in 1814, and served in Decatur's squadron in the Algerine war. Subsequently he assisted in the capture of slavers off the coast of Africa. In command of the Ohio in 1846 he took part in the bombardment of Vera Cruz. He was in constant service on sea or shore duty till 1861, when he became flag officer of the Atlantic blockading squadron, and in August coöperated in the capture of Forts Hatteras and Clark on the coast of North Carolina. He was promoted to rear admiral on the retired list in 1862, was commandant of the Charleston navy yard in 1864–'6, and was made port admiral of New York in 1867.

**STRISORES**, a suborder of insessorial or perching birds, without song, comprising such as have the hind toe capable of being turned more or less laterally forward, having apparently all four of the toes in front. It includes the families of the humming birds, swifts, and goatsuckers. (See ORNITHOLOGY.)

**STRONG, Caleb**, an American statesman, born in Northampton, Mass., Jan. 9, 1745, died there, Nov. 7, 1819. He graduated at Harvard college in 1764, and was admitted to the bar in 1772. During the revolution he was a member of the general court and of the Northampton committee of safety. He held several state offices, was a member of the convention for framing a national constitution, was elected one of the first United States senators from Massachusetts in 1789, was reëlected in 1793, and resigned in 1796. From 1800 to 1807 he was governor of Massachusetts, and again from 1812 to 1816. As a federalist he was opposed to the war with England, and believed himself justified on constitutional grounds in disregarding the president's requisition for troops, while amply providing for the defence of the state. (See MILITIA, vol. xi., p. 541.)

**STRONG, James**, an American author, born in New York, Aug. 14, 1822. He graduated at Wesleyan university, Middletown, Conn., in 1844, and in 1844–'6 was a teacher in the Troy conference academy, Poultney, Vt. In 1847 he settled at Flushing, Long Island, where he held several local offices, projected and as president constructed the Flushing railroad, laid out a cemetery and two suburban villages, and taught Greek and Hebrew to private pupils. In 1856, although a layman, he received the degree of S. T. D. from Wesleyan university. In 1858–'61 he was professor of Biblical literature and acting president of the Troy university; and in 1868 he became professor of exegetical theology in Drew theological seminary, Madison, N. J. In 1874 he made an extended tour in the East. He is a member of the Anglo-American commission for the revision of the authorized English Bible, and of the Palestine exploration society, and president of the oriental topographical corps. His chief literary work is the "Cyclopædia of Biblical, Theological, and Ecclesiastical Literature," projected by him and Dr. John McClintock in 1853, in which he had charge of the department of Biblical literature, and Dr. McClintock, to the time of his death in 1870, of theological and ecclesiastical literature. Since that date Dr. Strong has been supervising editor of the whole work, assisted by Prof. J. H. Worman. The first volume appeared in 1867, and the sixth in 1875; and it is to be completed in ten volumes. Dr. Strong has also published "Harmony and Exposition of the Gospels" (New York, 1852); "Greek Harmony of the Gospels" (1854); brief manuals of Greek and Hebrew grammar; and articles on Biblical topics and on ministerial education, the latter eliciting much controversy; and he prepared the part on Daniel for the English translation of Lange's "Commentary" (New York, 1875).

**STRONTIUM**, one of the three metals of the alkaline earths, barium and calcium being the other two. It was first obtained from the native carbonate of strontium by Sir Humphry Davy in 1808, in a manner similar to that for barium. The pure metal may be more readily obtained from the fused chloride by electrolysis according to the method of Matthiessen. A small porcelain crucible, having a porous cell in the middle, is filled with anhydrous chloride of strontium mixed with a little sal ammoniac. The negative electrode, consisting of a thin iron wire wound round a thicker one, and all but about $\frac{1}{16}$ of an inch covered with a piece of tobacco-pipe stem, is placed in the porous cell. The positive electrode, in the form of an iron cylinder, is placed in the crucible round the porous cell. The heat is so regulated that a crust shall form in the cell, under which the metal collects during the passage of the galvanic current. The pure metal has a pale yellow color and a specific gravity of 2·54. Its symbol is Sr; its atomic weight, 87·6. When heated in the air it burns with a crimson flame, emitting sparks, and decomposes water with evolution of hydrogen gas. It is about as hard as gold, very ductile, and may be hammered into very thin plates. With oxygen it forms two anhydrous oxides: strontium monoxide, $SrO$, and strontium dioxide, $SrO_2$, each of which unites with water to form a hydrate. The oxide, called strontia, has the same relation to the metal that lime has to calcium; and, like lime, one of its most important compounds is the carbonate, or strontianite, which was discovered in 1787 at Strontian in Argyleshire, Scotland, whence the

name. The mineral was then regarded as a carbonate of barium, but Crawfurd's supposition that it contained a peculiar earth was confirmed by Hope in 1792, and by Klaproth in 1793.—*Principal Salts.* The chloride ($SrCl_2$), the iodide ($SrI_2$), and the bromide ($SrBr_2$) are all easily soluble in water and decomposable by heat. The nitrate ($Sr2NO_3$) is extensively used in producing the crimson lights of fireworks. A mixture of 40 parts of strontium nitrate with from 5 to 10 parts of potassic chlorate, 12 of sulphur, and 4 of antimonious sulphide, deflagrates with a magnificent crimson color. Its preparation is dangerous, in consequence of its liability to ignite spontaneously. Nitrate of strontia may be prepared by treating the native carbonate with dilute nitric acid, but it is more usual to employ the native sulphate, which is reduced to a sulphide by heating it with charcoal, and then subjected to the action of dilute nitric acid. It crystallizes from hot, concentrated solutions in anhydrous octahedrons, which are insoluble in alcohol, but soluble in half their weight of boiling water and in five parts of cold water. From the cold solution it may be obtained in monoclinic crystals, having four molecules of water. Sulphate of strontium ($SrSO_4$) is found native as the mineral celestine, so named from its occasional delicate blue color, although it occurs white, gray, yellow, and red. It may also be prepared by the action of sulphuric acid on strontianite, or of a soluble strontia salt, as the nitrate, on another metallic sulphate. Its crystals are modifications of the right rhombic prism, being isomorphous with the sulphates of barium and calcium. The mineral is usually associated with limestone, or sandstone of the Silurian, Devonian, and other formations. It is also found in beds of gypsum, rock salt, and clay, and sometimes in trap rocks, and with volcanic sulphur. Splendid crystals are found at Girgenti, Sicily, associated with sulphur and gypsum. It is found at Bex in Switzerland, at Dornburg in Saxe-Weimar, in Tyrol, in rock salt at Ischl in Austria, and in trap rocks near Tantallan in East Lothian, Scotland. Beautiful bluish crystals occur in Trenton limestone about Lake Huron, particularly on Strontian island, and at Kingston, Canada. Fine specimens have been found at Schoharie and at Lockport, N. Y. A blue, fibrous celestine is found near Frankstown, Huntingdon co., Pa.; on Drummond island, Lake Erie, it occurs mixed with barium.

**STROSSMAYER, Joseph George,** a Croato-Slavonian prelate, born in Eszék, Feb. 4, 1815. He was educated at Pesth, Vienna, and Padua, and became bishop of the united sees of Bosnia and Sirmia, May 20, 1850. At the Vatican council he strenuously maintained the inopportuneness of defining the doctrine of pontifical infallibility. He was represented as having delivered a violent opposition speech in one of the sessions, the text of which was reproduced by several journals; but in 1872 he addressed a letter to the *Français* denying the authenticity of this speech, and affirming that he "never said one word during the entire council which could in any way diminish the authority of the holy see, or tend to promote discord in the church." He is known as a zealous champion of Slavic autonomy, and a munificent promoter of Slavic culture. In 1875 he published a pastoral letter on the occasion of his 25th anniversary as bishop, declining a public manifestation in his honor, "while the fellow countrymen of the Croats across the frontier are shedding their blood for liberty, and Christian charity makes it a duty to aid the widows and orphans of the fallen."

**STROTHER, David Hunter,** an American artist, born in Martinsburg, Va., Sept. 26, 1816. He studied drawing and painting, in 1845 went to New York, learned to draw on wood and illustrated some books, and in 1849 returned to Virginia. From 1853 till 1861 he published, under the pseudonyme of Porte Crayon, a series of illustrated papers, mostly relating to Virginia and the south, some of which were collected in his "Virginia Illustrated" (New York and London, 1857). On the outbreak of the civil war he volunteered in the United States service, was a colonel of cavalry, and at the close retired as a brevet brigadier general. Since 1866 he has resided at Berkeley Springs, W. Va., and continues his illustrated papers on southern subjects.

**STROUSBERG, Bethel Henry,** known as doctor, a German adventurer, born of Jewish parents at Neidenburg, East Prussia, Nov. 20, 1823. His original name was Baruch Hirsch Strausberg. In 1835 he entered the commission house of his uncles in London, became a Christian, and married an English woman. He finally engaged in the insurance business, incurred losses in 1847, taught languages at New Orleans in 1848, returned in 1849 to London with money made by trading in damaged goods, and was interested in publishing "The Chess Player," "Lawson's Merchant's Magazine," and "Sharpe's London Magazine." In 1855 he settled in Berlin as agent for an insurance company, and in 1861 obtained for English capitalists the concession of an East Prussian railway. After building other railways for different companies, he built many on his own account, chiefly in northern Germany, Hungary, and Roumania, and became the owner of vast establishments for producing all the materials required for them, as well as of beet-sugar, porcelain, and other factories, mines, the Berlin cattle yard, the Antwerp south citadel grounds, and the great Zbirow domain in Bohemia. At one time he employed more than 100,000 persons, and was engaged in speculations involving several hundred millions of dollars. He eclipsed princes in his luxurious living and ostentatious charities, and was popularly known in Berlin as

*Der Wunderdoctor.* He lost heavily during the war of 1870-'71, became inextricably involved in 1872 after a ruinous settlement with the Roumanian government on account of unfulfilled railway contracts, failed in 1875, and in November was imprisoned at Moscow for alleged fraudulent transactions with a bank.

**STRUENSEE, Johann Friedrich,** count, a Danish statesman, born in Halle, Aug. 5, 1737, executed at Copenhagen, April 28, 1772. He became in 1768 the physician and favorite of King Christian VII., and subsequently of his queen, Carolina Matilda. The king gave himself up to vicious indulgence, while the queen dowager led by Count Bernstorff, and the party of the queen led by Struensee, strove for power. The latter triumphed, and Struensee was appointed prime minister. After instituting important reforms, he became obnoxious on account of his arbitrary measures and his alleged illicit relations with the queen, and his enemies finally procured his ruin. (See CHRISTIAN VII., and CAROLINA MATILDA.)

**STRUTT, Joseph,** an English antiquary, born in Springfield, Essex, Oct. 27, 1742, died in London, Oct. 16, 1802. He studied painting and engraving, afterward engaged in antiquarian researches in the British museum, and published "The Regal and Ecclesiastical Antiquities of England, containing the most authentic Representations of the English Monarchs from Edward the Confessor to Henry VIII." (4to, 1773; new ed. by J. R. Planché, 1842); "Horda-Angel-Cynnan, or a Complete View of the Manners, Customs, Arms, Habits, &c., of the Inhabitants of England from the arrival of the Saxons till the Reign of Henry VIII." (3 vols. 4to, 1774-'6); "The Chronicle of England" (2 vols. 4to, 1777-'8), intended to comprise 6 vols., but terminated with the Norman conquest; "Biographical Dictionary of Engravers" (2 vols. 4to, 1785-'6); "Complete View of the Dress and Habits of the People of England, from the Establishment of the Saxons in Britain to the present Time" (2 vols., 1796-'9; new ed., 1875); and "The Sports and Pastimes of the People of England" (4to, 1801), well known by Hone's edition (8vo, 1830; latest ed., illustrated, 1875). He left a fragment of a romance entitled "Queen Hoo Hall," edited by Sir Walter Scott (1808), and other writings published posthumously. Strutt engraved a series of plates illustrating the "Pilgrim's Progress."

**STRUVE. I. Friedrich Georg Wilhelm von,** a Russian astronomer, born in Altona, April 15, 1793, died in St. Petersburg, Nov. 23, 1864. He was educated at Dorpat, and in November, 1813, was appointed extraordinary professor of mathematics and astronomy there, two years later becoming ordinary professor. His duty in that office was not only to attend to the observatory, but also to lecture on astronomy and mathematics; but in 1822 the two offices were separated, and Struve was henceforth free to work exclusively as an astronomer. In 1839 he was made director of the observatory of Pulkova, which had been built under his direction, and not long after he was made councillor of state. He confined his labors as an astronomer principally to the observation of fixed and double stars, and made large additions to the knowledge of these bodies. He also conducted the triangulation of Livonia, and measured the degrees of latitude in the Baltic provinces, and an arc of the meridian between Norway and southern Russia. In 1857 Struve visited England to organize and arrange the measurement of an arc of parallel through the entire breadth of Europe, from Orsk at the foot of the Ural mountains to Valentia at the western extremity of Ireland. This work he fairly initiated, but in 1858 he was attacked by a malady which prevented him from coöperating further in it save by advice and calculation; and in December, 1861, he was compelled to resign his active duties as director of the observatory. His most important works are: *Observationes Dorpatenses* (8 vols., Dorpat, 1817-'39); *Catalogus Novus Stellarum Duplicium* (1827); *Stellarum Duplicium Mensuræ Micrometricæ* (St. Petersburg, 1827); *Description de l'observatoire astronomique central de Russie* (1845, with 36 plates); *Études d'astronomie stellaire sur la voie lactée et la distance des étoiles fixes* (1847); and *Stellarum Fixarum imprimis Duplicium et Multiplicium Positiones Mediæ pro Epocha* 1830, &c. (fol., 1852).—See a memoir by Prof. Cleveland Abbe, in the appendix to the report for 1869 of the secretary of the Smithsonian institution. **II. Otto Wilhelm,** son of the preceding, born at Dorpat, May 7, 1819. He became his father's assistant at Pulkova in 1839, and succeeded him as director in 1862. From 1847 to 1862, as consulting astronomer, he had the oversight of all investigations conducted by the Russian army and navy. His labors relate chiefly to nebulæ, double stars, faint satellites, and comets, and include a new determination of the constant of precession, the discovery of about 500 new double stars, most of them barely separable, the determination of the mass of Neptune, investigations in regard to Saturn and his rings and to the parallax of various fixed stars, and observations of the nebula of Orion. He first showed that the red prominences visible in a total solar eclipse belong to the sun's surface. Besides numerous papers in the *Mémoires* of the academy of St. Petersburg, he has published *Uebersicht der Thätigkeit der Nikolai-Hauptsternwarte während der ersten 25 Jahre ihres Bestehens* (St. Petersburg, 1865).

**STRUVE. I. Georg Adam,** a German jurist, born in Magdeburg, Sept. 26, 1619, died in Jena, Dec. 15, 1692. He studied law at Jena and Helmstedt, and in 1646 was appointed professor of law at Jena, and in 1648 assessor to the high court of the circle of Saxony. In 1667 he was appointed privy councillor to the duke of Weimar, and was selected as his advocate in the case of the succession to the

duchy of Saxe-Altenburg. In 1674 he returned to Jena as professor of canon law and *ordinarius* of the judicial college, and in 1680 was appointed president of the regency of Weimar, the duke being a minor. He published 13 elaborate treatises on law, of which the most important are: *Syntagma Juris Feudalis* (Jena, 1653); *Syntagmata Jurisprudentiæ Civilis* (1665); and *Jurisprudentia Romano-Germanica Forensis* (1670). **II. Burkhard Gotthelf,** a German jurist, son of the preceding, born in Weimar, May 26, 1671, died in Jena, May 24, 1738. He studied at Jena and various other German and Dutch universities, and in 1692 engaged at Jena with his brother in the pursuit of the philosopher's stone, in which they soon beggared themselves. In 1704 he became professor of history, and in 1712 extraordinary professor of law. The most important of his numerous works is his *Corpus Juris Gentium* (Jena, 1743).

**STRYCHNIA,** or **Strychnine,** a poisonous vegetable alkaloid, discovered in 1818 by Pelletier and Caventou in the seed of the *strychnos multiflora* or St. Ignatius' bean, and the *strychnos nux-vomica*. (See Nux Vomica.) It is associated with brucia, an alkaloid having similar poisonous properties, but of much less strength. (See Brucia.) Strychnia is also said to be contained in larger proportions in the seeds of the *strychnos tieuté*, a native of Java, from which the poison called upas tieuté is extracted. In preparing strychnia, the seeds of the plant may be first softened by steam and sliced, dried, and ground, or they may be reduced to a pulp by beating. The following is Merck's process for extracting the alkaloid: The seeds are boiled for 24 or 36 hours in a closed boiler with water enough to cover them, acidulated with one eighth of its weight of sulphuric acid. They are then beaten into a paste, and the liquor is expressed. Excess of caustic lime is added, which throws down the alkaloids. The precipitate is then boiled in alcohol of specific gravity 0·850, and filtered hot. Strychnia and brucia are deposited together in a colored and impure state, and may be separated by cold alcohol, which dissolves the brucia. The remaining strychnia is then boiled in alcohol with a little animal charcoal, and the solution filtered boiling hot. On cooling, the strychnia crystallizes in small brilliant, colorless, octahedral crystals, soluble in about 7,000 parts of cold and 2,500 parts of boiling water.—Strychnia is inodorous, but has an exceedingly bitter taste, which is perceptible when the drug is dissolved in 1,000,000 parts of water. It is one of the most active and powerful poisons. The symptoms it produces are difficulty of breathing and a sense of suffocation, twitching of the limbs and tetanic convulsions, the body becoming arched in the back, often resting on the head and heels, a condition known as *opisthotonos*. The features are convulsed, attended by spasm of the jaws and choking. The attack occurs in paroxysms, between which the intellect is often clear at first, but becomes clouded after a succession of paroxysms. The medical properties of strychnia are like those of nux vomica, which was employed by the Arabian physicians. In small doses it acts as a tonic, and it is often given as an adjunct to laxative pills, particularly to dinner pills, in debilitated conditions of the muscular coat of the intestines. When given in larger doses its action is directed to the motor nerves, probably through the medium of the spinal marrow. It produces trembling in the limbs, and a tendency to involuntary muscular contraction, as in tetanus, and frequent starts and spasms occur as from electric shocks, which are increased in intensity by a perseverance in the medicine. It sometimes produces pain in the head, vertigo, contracted pupils, and dimness of vision. The pulse is not particularly affected, though sometimes slightly accelerated. It has been employed on the continent of Europe as an antidote to the plague, in intermittent fevers, and as a remedy in mania, hysteria, rheumatism, and hydrophobia. It is said to have cured spasmodic asthma. Its peculiar influence upon the nerves of motion, to which attention was first called by Magendie, caused M. Fouquier, a French physician, to use it in paralytic affections, and it is now considered a standard remedy in palsy. It is a singular fact that its action is directed first to the muscles of the paralytic part. Its action varies in degree with different animals, being particularly marked upon the canine race. Pelletier and Caventou killed a dog in half a minute with one sixth of a grain. One grain might prove fatal in the human subject; indeed, half a grain proved fatal in the case of Dr. Warner. One twelfth of a grain every four hours, repeated several times, will cause decidedly unpleasant symptoms; but a great difference in its effects is observed in different individuals, some being affected by the administration of one thirtieth of a grain two or three times repeated, while others have been said to take more than a grain at a time, and as much as three grains in the course of 24 hours.—Many antidotes have been proposed. According to M. Duclos, its poisonous effects subside under the application of negative electricity, while they are aggravated by positive. Kermes mineral has been recommended by M. Thorel, being thought by him to form an insoluble sulphuret, and he recommends the administration at the same time of an emetic. Tannic acid, chlorine, and tinctures of iodine and bromine are regarded as the best antidotes by Prof. Bellini. The indications are to evacuate the stomach as quickly as possible, and for this the stomach pump is the most efficient means. In its absence sulphate of zinc or powdered mustard may be used. To relieve the spasms various narcotics have been used, as conium, opium, and *cannabis Indica*, and the reports of their effect are in some

cases decidedly favorable. Chloroform is said to have been used with good effects.

**STRYMON.** See Macedonia.

**STRYPE, John,** an English clergyman, born in London, Nov. 12, 1643, died Dec. 13, 1737. He was educated at St. Paul's school and at Cambridge, and from 1669 till about 1732 he was minister of Low Leyton in Essex. His works include "Memorials of the most renowned Father in God, Thomas Cranmer, sometime Lord Archbishop of Canterbury" (fol., 1694); "The Life of the Learned Sir Thomas Smith" (8vo, 1698); "Historical Collections relating to the Life and Acts of Bishop Aylmer" (8vo, 1701); "Annals of the Reformation" (4 vols. fol., 1709–'31); and "Ecclesiastical Memoirs" (3 vols. fol., 1721). He published an edition of Stow's "Survey of London" (2 vols. fol., 1720), with important additions of his own. His works have been reprinted at Oxford (29 vols. 8vo, 1822–'8).

**STUART,** or **Stewart,** the name of a royal family of Scotland and England. According to tradition, Fleanchus, son of Banquo, on the murder of his father by Macbeth, fled into Wales in 1055, where he married a daughter of a chief named Griffithar Llewellyn; the son of Fleanchus, Walter I. (died 1113), returned to Scotland, and became steward of the household of Malcolm III., which office was made hereditary in his family, and from which the surname Stewart was derived. Walter was succeeded by his son Alan, he by another Walter, and the latter by Alexander, who in 1199 was slain in a battle with the Danes, and left his office to his son Walter III., who conspired against King Alexander II., and was subsequently poisoned by his wife Alda of Dembe. Walter's son and successor Alexander was regent during the minority of Alexander III. His son James was regent after the death of that king, and died in 1309. Walter IV., who succeeded his father, married Marjory, daughter of Robert Bruce, in 1315, upon whom, in failure of the birth of an heir male to her father, the crown was settled by act of parliament at Ayr, April 26, 1315. Marjory died in giving birth to Robert, afterward Robert II. of Scotland; but David II., son of Robert Bruce by a second marriage, came to the throne in 1331 as a minor. A succession of regencies followed, in which Robert the Stewart and the earl of Murray were distinguished, the former at intervals till 1357, when David, captured by the English in 1346, was released and resumed his throne. On the death of David, Robert was unanimously declared king with the title of Robert II. (February, 1371). His licentiousness, and the questioned legitimacy of his first wife's children, with chronic war against England, rendered his reign and that of his son Robert III. harassing and unfortunate for the people. Robert II. died in 1390, and Robert III. in 1406. The succeeding monarchs of the line (all of whom are treated in separate articles) were James I., assassinated in 1437; James II., who was accidentally killed in 1460; James III., murdered in 1488; James IV., slain in the battle of Flodden in 1513; James V., son of the preceding and of Margaret Tudor, sister of Henry VIII. of England, who died in 1542; Mary, executed in England in 1587; her son James VI., who succeeded Queen Elizabeth as James I. of England, and died in 1625; Charles I., executed in 1649; Charles II., who died in 1685; James II., who died in 1701, and was the last reigning male member of the family, though his daughter Mary, wife of William of Orange, came to the throne after his expulsion in 1688 as queen regnant with her husband, and his second daughter Anne succeeded her in 1702, reigning till her death in 1714. The only son of James II., James Francis Edward Stuart, was a pretender to the throne of England, and died in Rome in 1766. His son Charles Edward Stuart (born in 1720, died in 1788) was a second pretender. Henry Stuart, Cardinal York, brother of Charles Edward, was the last of the male line of the family, and with his death in 1807 it became extinct. Its chief branches in the female line are the houses of Savoy and Orleans, both descended from Henrietta Anna, daughter of Charles I. The late duke of Modena, who was that king's lineal representative, and thus, but for the act of settlement, heir to the crown of England, died childless in November, 1875. (See Charles Edward, James Francis Edward, and Stuart, Henry Benedict Maria Clement.)

**STUART, Arabella** or **Arbella,** often called the lady Arabella, the only child of Charles Stuart, earl of Lennox, brother of Darnley and uncle of James I., born about 1575, died in the tower of London, Sept. 27, 1615. She was related to Queen Elizabeth in the same degree as her cousin James, the successor to the throne; and this relationship made her the subject of constant intrigues. An early plan to marry her to her relative Lord Esme Stuart was defeated by Elizabeth's opposition; several similar schemes failed from various causes; and she was still unmarried when in 1603 Sir Walter Raleigh was accused of a plot to raise her to the throne. This design probably never existed, but the accusation brought her into public notice, and made her situation still more dangerous; and further hostility was aroused against her by the discovery in 1610 that she had been secretly married to William Seymour, grandson of the earl of Hertford. Seymour was at once committed to the tower, and the lady Arabella placed in the custody first of Sir Thomas Parry at Lambeth and afterward of the bishop of Durham. While on the journey to Durham she escaped by feigning illness (June, 1611), and made her way to a French vessel waiting for her and her husband, the latter having also escaped from the tower. He did not get to the ship, which sailed without him; but it was captured before reaching the French coast, while the small vessel in which

he took passage later made the passage safely. Lady Arabella was thrown into the tower, where she became ill from neglect and ill treatment, and finally insane a short time before her death.

**STUART, Gilbert,** a Scottish author, born in Edinburgh in 1742 or 1746, died in Musselburgh, Aug. 13, 1786. He was educated at the university of Edinburgh, and in 1767 published a "Historical Disquisition concerning the Antiquity of the British Constitution," which procured him the degree of LL. D., and in 1768 "View of Society in Europe in its Progress from Rudeness to Refinement." He failed to procure a professorship in Edinburgh on account of his dissipation, spent several years in London, and in 1773 started the "Edinburgh Magazine and Review," in which for four years he published savage attacks upon prominent Scottish authors. He afterward again lived for some time in London. His remaining works are: "Observations concerning the Public Law and Constitutional History of Scotland" (8vo, Edinburgh, 1779), an attack on Dr. Robertson, whom he especially hated; "History of the Establishment of the Reformation of Religion in Scotland" (4to, London, 1780); and "History of Scotland from the Reformation to the Death of Queen Mary" (2 vols. 8vo, London, 1782).

**STUART, Gilbert Charles,** an American painter, born in Narragansett, R. I., in 1756, died in Boston in July, 1828. He received his first instructions from a Scottish painter named Alexander, by whom, when about 18 years of age, he was taken to Edinburgh. His master died soon after their arrival in that city, and Stuart worked his passage home before the mast, and began practice as a portrait painter at Newport, R. I. He removed successively to Boston and New York, and set sail in 1778 for London, where for two years he made little progress, and suffered greatly from poverty; but becoming acquainted with Benjamin West, he received valuable assistance from him, and for several years resided in his family. About 1781 he began practice in London on his own account, and soon rose to great eminence as a portrait painter, rivalling Reynolds and the best English artists of the day. Subsequently he resided successively in Dublin and Paris, and in 1793 returned to America. He went to Philadelphia to paint a portrait of Washington, and destroyed his first picture; but at the second sitting he produced the well known head from which he painted all his other portraits of Washington, and which has long been regarded as the standard likeness. The original study, together with a head of Mrs. Washington, is now in the possession of the Boston Athenæum. After residing several years in Washington, he settled in 1806 in Boston. As a painter of heads he holds the first place among American painters, if we except Copley, and his flesh coloring rivals the finest modern efforts. Upon accessories he bestowed little labor, and they are sometimes finished in the most slovenly manner.

**STUART, Henry Benedict Maria Clement,** Cardinal York, the last of the Stuart family in the male line, born in Rome in 1725, died at Frascati in 1807. He was the son of the pretender James Francis Edward, who created him duke of York, and the younger brother of the "young pretender" Charles Edward, whom he was preparing to aid with a body of French troops assembled at Dunkirk when the overthrow of the Jacobites at Culloden ruined the Stuart cause in Britain. He subsequently took orders in the Roman Catholic church, and in 1747 was appointed by Benedict XIV. a cardinal, the ducal title given him by his father, though valueless in England, being recognized by the pope in the style of his nomination as Cardinal York. On the death of his brother in 1788 he assumed the title of king of England as Henry IX., *gratia Dei, non voluntate hominum*, as the medal struck on the occasion declared. On the occupation of the Papal States by the French he retired to Venice, and in his last years was dependent upon the British court for the means of subsistence.

**STUART, James,** sometimes called Athenian Stuart, an English antiquary, born in London in 1713, died Feb. 2, 1788. In early life, till about 1742, he painted fans. He then went to Rome, where he studied art, the ancient languages, and archæology. In 1750 he accompanied Nicholas Revett on an antiquarian tour to Greece, remaining in Athens from March, 1751, to the close of 1753. Returning to London in 1755, he engaged in the practice of architecture, and began, at first in conjunction with Revett, a work on the "Antiquities of Athens." The work was completed in 4 vols. imp. fol., with 384 plates; the first volume appeared in 1762, and the other three were edited respectively by Newton (1787), W. Reveley (1794), and Joseph Woods (1816). A second edition of the first three volumes with smaller plates, and a supplementary volume with 50 plates, were published by Kinnard (1825–'30). Among other editions is one in French (4 vols. fol. and a supplementary volume, Paris, 1808–'32).

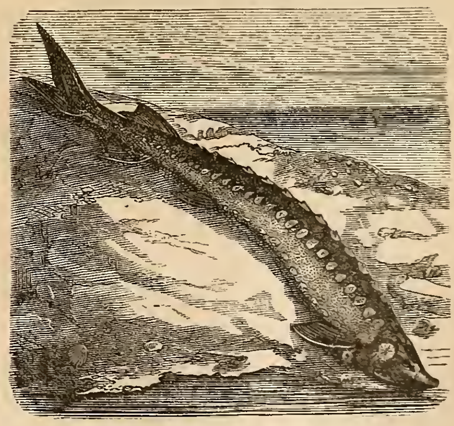
**STUART, John,** earl of Bute. See Bute.

**STUART, Moses,** an American author, born at Wilton, Conn., March 26, 1780, died in Andover, Mass., Jan. 4, 1852. He graduated at Yale college in 1799, was admitted to the bar in 1802, and for the two succeeding years was a tutor in Yale college. He afterward studied theology, and was ordained pastor of the first Congregational church of New Haven, March 5, 1806. From 1809 to 1848 he was professor of sacred literature in the theological seminary at Andover. He published a "Grammar of the Hebrew Language without Points" (Andover, 1813); "Letters to the Rev. William E. Channing, containing Remarks on his Sermon recently preached and published in Baltimore" (1819); a "Grammar of the Hebrew Language

with Points" (1821); "Letters to Dr. Miller on the Eternal Generation of the Son of God" (1822); "Commentary on the Epistle to the Hebrews" (2 vols. 8vo, 1827–'8); "Hebrew Chrestomathy" (2 vols., 1829–'30); "Exegetical Essays upon Several Words relating to Future Punishment" (1830); "Commentary on the Epistle to the Romans" (1832); "Is the Mode of Christian Baptism prescribed in the New Testament?" (1833); "A Grammar of the New Testament Dialect" (1834); "Philological View of Modern Doctrines of Geology" (1836); "Hints on the Prophecies" (2d ed., 1842); "Commentary on the Apocalypse" (2 vols., 1845); "Critical History and Defence of the Old Testament Canon" (1845); "Commentary on Daniel" (1850); "Conscience and the Constitution" (1851); "Commentary on Ecclesiastes" (New York, 1851); and "Commentary on Proverbs" (1852). He also published several translations, including "Elements of Interpretation," from the Latin of Ernesti (Andover, 1822); "Hebrew Grammar," from the German of Gesenius (1825); with Edward Robinson, "Greek Grammar of the New Testament," from the German of Winer (1825); and "Discrepancies between the Sabellian and Athanasian Methods of Representing the Doctrine of the Trinity," from the German of Schleiermacher (1835).

**STUHL-WEISSENBURG. I.** Properly Weissenburg (Hung. *Fejér*), a county of S. W. Hungary, bounded E. by the Danube; area, 1,605 sq. m.; pop. in 1870, 196,234, chiefly Magyars. The N. part of the county is mountainous, while the S. is level. Among the products are tobacco, wine, and marble, and there are several mineral springs. **II.** A city, capital of the county (Hung. *Székes-Fejérvár;* Lat. *Alba Regia*), on the left bank of the Csorgó, near the border of an extensive morass, 38 m. S. W. of Buda; pop. in 1870, 22,683. The principal buildings are the cathedral and the episcopal palace. There are manufactures of woollen and linen goods, hardware, and several other articles. The kings of Hungary were crowned here down to Ferdinand I., and the cathedral contains many of their tombs. Four tombs dating from the 13th century, and other relics, were excavated in 1874, including those of a remarkable chapel.

**STURGEON,** the name of cartilaginous fishes of the class of ganoids and family *sturionidæ.* The body is elongated and fusiform, covered with a rough skin protected by five longitudinal rows of tubercular plates; the largest of these rows is along the back, and there is also one on each side, and one from each pectoral to the ventral fins; the plates are flattened, and marked with radiating striæ. The head is depressed, and ends in a long triangular snout covered with bony plates; mouth funnel-shaped and protrusible, on the under surface, without teeth, having in front a few depending barbels, evidently organs of touch; gill covers very large and gills free; pseudo-branchiæ and spiracles are present, but no branchiostegal rays; fins well developed, the dorsal and anal opposite and behind the ventrals; tail heterocercal or unsymmetrical, the vertebral cord being prolonged into the upper lobe as in the sharks, and strengthened by fulcra along its upper margin; a soft caudal on the under surface of the tail. The vertebral column consists of an undivided soft *chorda dorsalis;* the air bladder is very large, communicating freely with the œsophagus; there is a spiral valve in the intestine, and a conglomerate pancreas. They are generally large, and inhabit the northern temperate seas of both coasts of America, eastern Europe, and western Asia, from which they ascend the rivers in spring to spawn, returning to the salt water in autumn; species are also found in the great American fresh-water lakes, which never descend to the sea. They are oviparous; the food consists of any soft substances which they stir up from the bottom with their snouts, and of small fish; they frequently jump out of water.—The genus *acipenser* (Linn.) has the characters of the family. The common sturgeon of Europe (*A. sturio*, Linn.) attains a length of 6 to 10 ft., and sometimes more; it is found in the Caspian and Black seas and the rivers opening into them, and sometimes on the coasts of Great Britain and the Baltic; the flesh is delicate, and is largely consumed in



Common European Sturgeon (Acipenser sturio).

Russia, fresh, salted, and pickled. A larger species, also found in the seas and rivers of S. E. Europe, is the beluga (*A. huso*, Linn.), attaining a length of 12 to 15 ft. and a weight of 1,200 lbs., and occasionally much larger; it ascends the rivers opening into the Caspian and Black seas, with other and smaller species. The flesh is tough; the sound or air bladder furnishes an abundant supply of isinglass, for which great numbers are caught in Russia. Caviare is also made from the roe of the female, which sometimes constitutes one third of the weight of the fish; the skin is used for

harness leather, and the dorsal cord, cut in pieces and dried, is used as food. The sterlet (*A. Ruthenus*, Linn.), found in the Caspian, and growing to a length of 2 or 3 ft., furnishes a most delicate food and the best caviare. In the Volga it spawns early in May, on rocky bottoms, in water of 54° F.; the eggs, which are easily fecundated artificially, soon adhere to any object; they are hatched in about seven days, the embryos being then about a quarter of an inch long; in ten weeks these attain a length of two inches, feeding on larvæ of insects on the bottom. Both eggs and young will safely bear a journey of five days, and have been carried to W. Russia, and even to stock British rivers; the young live only in fresh water. The color in these species is brown of various shades, the plates whitish, and the abdomen silvery. The several species in the Baltic hybridize freely, and are probaby only varieties of one.—In North America sturgeons are not found north of the watersheds between lat. 53° and 54° N., where the mean annual temperature is about 33° F.; they seldom enter clear cold streams, but ascend muddy rivers in such numbers that many large Indian tribes subsist entirely on their flesh in summer; each watershed has its own species, varying in some minor characteristics. The sharp-nosed sturgeon (*A. oxyrhynchus*, Mitch.) attains a

Sharp-nosed Sturgeon (Acipenser oxyrhynchus).

length of from 3 to 7 ft.; it is found on the coasts of New England, New Brunswick, and Nova Scotia; it is common in Long Island sound from the middle of June to October, and is taken by harpoon and in nets; the smaller specimens are esteemed for the table; it is grayish brown above, silvery on the sides, and white below. The short-nosed sturgeon (*A. brevirostris*, Mitch.) is dusky above and white below; the snout is short and blunt; it attains a length of 2 to 5 ft., and is so common in the Hudson that its flesh in the market has been known as Albany beef; it much resembles the *A. sturio* of Europe. Other species are described from the northern waters, the rivers of the N. W. coast, and from Lake Superior, by Richardson and Agassiz.—The genus *polyodon* (Lacép.) or *spatularia* (Shaw) has the general form of *acipenser*, but is without the bony plates on the body and head; the snout is very much elongated, and compressed into a thin leaf-like organ, partly bony and partly cutaneous, sometimes nearly as long as the body; gill covers very large, extending far back in a membranous point; the mouth is wide, with numerous minute teeth in the young animal, which are lost with age. The spoon-bill sturgeon (*P. folium*, Lacép.) is steel-blue above and white below; it attains a length of 5 ft., and is found in the Mississippi, Ohio, and their tributaries; it is also called shovel fish and paddle fish; the flesh is tough; the singularly shaped snout is used to shovel up the mud in search of food. The genus *platirostra* (Les.) is probably only the adult of *polyodon*, the principal difference being the absence of teeth.

**STURLESON.** See SNORRI STURLASON.

**STURT,** Sir **Charles,** an English explorer, died in Cheltenham, June 16, 1869. He entered the army at an early age, and in 1825 (being then a captain) was stationed at Sydney, New South Wales. At this time the interior of Australia was almost entirely unknown; and in 1828 Gen. Darling organized an exploring expedition. Oxley ten years before had been stopped by the great swamps W. of the Blue mountains, and this expedition was to penetrate beyond them as far inland as possible. Sturt was attached to the party, and soon took the virtual lead of it. He discovered the Macquarie, Castlereagh, and Darling rivers, and explored a great portion of their valleys. Later he led another expedition, explored the course of the Murrumbidgee, discovered (June 14, 1830) the great Murray river, followed it to Lake Alexandrina, and returned at the beginning of 1831. The account of these journeys was published in London in 1833, under the title of "Two Expeditions into the Interior of South Australia during the years 1828–'31." His health, and especially his eyesight, had suffered greatly; and he was compelled to rest for several years before undertaking his next expedition, which was overland from Sydney to Adelaide. At Adelaide he was made surveyor general of South Australia. In 1844 he undertook a fourth journey, and, after the greatest hardships in the Stony Desert, reached a point near the centre of the continent. This expedition he described in a report published in London in 1849. After his return he became registrar general and later colonial secretary of South Australia; but the injury to his eyes resulted in total blindness, and he returned to England. He was knighted a few days before his death.

**STUTSMAN,** an E. central county of Dakota, recently formed and not included in the census of 1870; area, about 2,100 sq. m. It is drained by the head waters of the Dakota or James river. The W. part is occupied by the Plateau du Coteau du Missouri. The Northern Pacific railroad traverses it from E. to W. The surface is rolling.

**STUTTERING.** See STAMMERING.

**STUTTGART,** a city of Germany, capital of the kingdom of Würtemberg, 2 m. S. W. of Canstatt on the Neckar, and 97 m. S. E. of Frankfort; pop. in 1876, over 107,000, including 9,000 in several villages. It stands in a very beautiful valley surrounded by vine-clad hills, with wooded mountains in the distance. The town is generally well built, and is divided by the long Königsstrasse, the principal street, extending nearly N. and S. throughout its en-

tire length, and bordered by the chief business buildings. In the principal square is a fine old Gothic church, with a high tower and many ancient sculptures and monuments of the princes of Würtemberg. The royal (formerly ducal) palace, begun in 1746 and finished

The Old Palace.

in 1806, is a large building of freestone finely decorated and furnished in the interior; the old palace, completed in 1570, resembles a mediæval castle, and is now occupied by officials connected with the government. In the same square is a monument to Schiller by Thorwaldsen. The hospital church is a Gothic building, finely decorated in the interior, and contains the original model of Dannecker's "Christ." The town hall was built in the 15th century. There is a museum of natural history; a royal library of 450,000 volumes and 3,500 manuscripts; a cabinet of medals containing more than 17,000 specimens; a museum of the fine arts, with many valuable statues and pictures; a bazaar, and a theatre. Stuttgart has also a gymnasium, military academy, polytechnic school, a royal school of art, attended in 1874–'5 by about 100 students, and a conservatory of music, attended in January, 1875, by 576 male and female pupils, including 79 from the United States and 53 from England. The manufactures include woollen, silk, linen, and cotton goods, jewelry, musical and philosophical instruments, leather, and tin ware. The book trade is extensive, and connected with it are numerous paper mills, type founderies, and lithographic establishments. The town is the central point of the Würtemberg railways, seven lines extending from it; and the railway station is perhaps the finest in Germany. There is a horse railway between Stuttgart and Canstatt, a pleasant suburb and favorite summer resort. Besides the public garden, which is one of the finest in Germany, there are in the vicinity numerous parks and gardens, where the public are admitted; that of Rosenstein, the king's summer palace, and the gardens of the Wilhelma palace at Canstatt, are the most beautiful.—The date of the foundation of Stuttgart is not accurately known. It is mentioned as early as 1229, and was selected as a residence by Count Eberhard in 1320. In 1482 Count Ulric made it the capital of Würtemberg. The city had little of its present beauty until the middle of the 18th century; after that time it was greatly improved during several successive reigns, owing its chief embellishments to Kings Frederick and William. The population and prosperity of Stuttgart have of late much increased.—See Wochner's *Stuttgart seit 25 Jahren* (Stuttgart, 1871).

**STUYVESANT, Petrus,** the last Dutch director general of New Netherland (New York), born in Holland in 1602, died in New York city in August, 1682. He served in the war in the West Indies, was director of the colony of Curaçoa, lost a leg in battle, and returned to Holland in 1644. In 1645 the Dutch West India company appointed him director general of New Netherland. He arrived in May, 1647, conciliated the savages, who had been provoked to hostilities by his predecessor William Kieft, and restored order in every department. In 1650 he arranged at Hartford with the New England commissioners a line of partition, before undefined and disputed, between the Dutch and English territories. In 1651 the Dutch built Fort Casimir on the Delaware, which was captured by Rising, the governor of New Sweden, in 1654. Next year Stuyvesant sailed into the Delaware with seven vessels and 600 or 700 men, and took the whole settlement. For the next ten years there was nearly unbroken peace. In 1653 a convention of two deputies from each village in New Netherland demanded that "no new laws shall be enacted but with the consent of the people; that none shall be appointed to office but with the approbation of the people; that obscure and obsolete laws shall never be revived." Stuyvesant commanded the separation of this assembly on pain of punishment, telling them: "We derive our authority from God and the company, not from a few ignorant subjects." The spirit of resistance nevertheless increased. The encroachments of the New England colonies induced Stuyvesant to remonstrate before a convention of the united colonies at Boston, but he met with little favor; and a second embassy to Hartford had no better success. In 1664 Charles II. granted to his brother, the duke of York, the territory from the Connecticut river to the shores of the Delaware, and an English fleet under Richard Nicolls appeared in the bay of New York in August and demanded the surrender of the city. Stuyvesant was unwilling to capitulate, but the municipality, seeing the futility of resistance, insisted on yielding; and at last he consented, and the city was given up on Sept. 3, 1664. Stuyvesant went in 1665 to report to his superiors in Holland, but returning, spent the remainder of his life on his farm or *bouwerij* (whence the name of the street called the Bowery), then outside the limits of the city. He lies buried in the vaults of St. Mark's church in 10th street.

**STY** (Lat. *hordeolum*, from *hordeum*, barley), a small inflammatory tumor on the edge of the

eyelid, about the size of a grain of barley. Sty has its seat in the cellular tissue at the margin of the lid, involving generally the roots of one or more of the eyelashes. The tumor is furuncular, and almost invariably goes on to suppuration; its progress is sometimes tedious and the suppuration imperfect. Sty is most common in persons of a strumous habit, and often has for an exciting cause derangement of the digestive organs. When the little tumor has made its appearance, it is best to promote its maturation by warm and emollient fomentations. It is commonly advisable to leave it to burst of itself; but when maturation has occurred, if it occasion much uneasiness, it may be punctured.

**STYLE, Old and New.** See Calendar.

**STYRAX.** See Balsams.

**STYLITES** (Gr. στυλίτης, belonging to a pillar), a class of anchorites who spent their lives on pillars. The originator of this mode of Christian penance was Simeon (known as St. Simeon Stylites), a Syrian, who was born in Sisan or Sesan about 390, and died near Antioch in 459. He spent several years in convents, but not being satisfied with the severity of their discipline, he built for himself on Mt. Telanissa a small hut, in which he inflicted upon himself all manner of bodily pains, in the hope of thereby attaining to spiritual perfection. His fame drew around him large numbers of admirers, and in order to escape their constant intrusions and persistent efforts to approach him and touch his garments, he decided to live on top of a pillar. At first he maintained himself standing upon it by means of a beam, but he soon learned to do without this support, and to obtain rest by leaning against the low parapet. His pillar was at first only about 10 ft. high, but he had it repeatedly increased in height, until it was about 60 ft. high. On this pillar, the top of which is said to have measured only a few feet in circumference, he lived upward of 30 years; and when he died the people of Antioch received his body into their city and revered him as their patron saint. His example found numerous imitators in the East, but his peculiar kind of asceticism met with little favor in the West. He and his followers received the designation of stylites, but are known also as air martyrs, pillarists, and pillar saints. There were several other stylites called Simeon. One died in 595, and another, one of the last recorded in history, lived in the 12th century. It is related of one Alypius that he maintained himself 70 years on a pillar near Adrianople.

**STYRIA** (Ger. *Steiermark*), a duchy of Austria, bordering on Upper and Lower Austria, Hungary, Croatia, Carniola, Carinthia, and Salzburg; area, 8,671 sq. m.; pop. in 1870, 1,137,990. It is divided into the circles of Gratz, which contains the capital of the same name, Marburg, and Bruck. It is traversed by three chains belonging to the Noric branch of the Alpine system, the highest summits of which are on the N. W. and S. W. frontiers, rising to an elevation of 8,000 ft. and upward. The N. W. part is known as Upper Styria, and the country in the opposite direction as Lower Styria. The surface belongs to the basin of the Danube. The most important streams are the Mur, Enns, Raab, Save, and Drave, all of which except the Raab are navigable for boats. There are numerous small lakes, and hot and mineral springs. Limestone, sulphur, alum, rock salt, gold, silver, lead, copper, cobalt, zinc, and iron ore of superior quality are found. The soil in the valleys is generally fertile, but no surplus of grain is produced. The vine thrives well. The forests cover about half the surface. The inhabitants are mostly German, but the Winds or Slovens are numerous, constituting about 36 per cent. of the population; nearly all are Roman Catholics. Iron is extensively manufactured, and linen, cotton, woollen, and silk to some extent; but the most important branch of industry is timber. Millions of jewsharps are annually exported.—Under the Romans the eastern part of Styria belonged to the province of Pannonia, and the western to Noricum. Christianity was introduced in the 4th century, but the northern barbarians afterward overran the province. Styria was annexed to Austria in 1192, was subsequently attached to Bohemia, and in 1276 together with other territories surrendered by King Ottocar II. to Rudolph I. of Hapsburg. It subsequently belonged to various branches of that house, until the Styrian line became the ruling one with the succession of Ferdinand II. to the emperor Matthias in 1619. Ferdinand exterminated Protestantism in the duchy. Under the constitution of Cisleithan Austria the Styrian diet elects 13 members to the Austrian Reichsrath.—See *Das Volksleben in Steiermark in Charakter- und Sittenbildern dargestellt*, by P. K. Rosegger (2 vols., Gratz, 1875).

**STYX** (connected with Gr. στυγεῖν, to abhor), in Greek mythology, the chief river of the lower world, around which it flows seven times. The name was said to be derived from the nymph Styx, the daughter of Oceanus, who, when Jupiter prepared to wrest the power from the hands of Saturn and the Titans, was the first of the immortals to answer to his call, coming with her children to his assistance. He made her children his constant attendants, and herself the oath-sanctioner of the gods. In the Hesiodic theogony Styx is called the daughter of Oceanus and Tethys. She was the mother of Zelos (zeal), Nike (victory), Bia (strength), and Cratos (power).

**SUABIA.** See Swabia.

**SUAKIN**, or **Suakim**, a seaport town of Nubia, on the coast of the Red sea, 285 m. N. N. W. of Massowah; lat. 19° 17′ N., lon. 37° 20′ E.; pop. about 6,000. The town proper is on an island 1½ m. in circumference, which is connected by a bridge with a suburb on the mainland. It is defended by a small fort,

and contains several mosques and public buildings, the principal of which are the governor's house, custom house, and bazaar. The harbor is sheltered from all winds, but is too shallow to admit large vessels. The adjacent country is a level plain. The climate is very hot. Suakin is fast increasing in commercial importance, and has a considerable trade in cattle, hides, butter, ivory, ostrich feathers, gum arabic, cotton, and coffee, the last from Abyssinia. More than 150 vessels enter its port yearly. It was formerly subject directly to the Turkish power, but in 1865 was surrendered to the viceroy of Egypt. In 1870 telegraphic communication was established with the Soodan, an attempt to effect which in 1865 had resulted in the loss of the engineers and 8,000 camels. There is a direct caravan route from Suakin to Berber, on the Nile, and to Khartoom, and great numbers of pilgrims pass over it yearly on their way to Mecca.

**SUAREZ, Francisco,** a Spanish theologian, born in Granada, Jan. 5, 1548, died in Lisbon, Sept. 25, 1617. He early entered the order of Jesuits, and was successively professor at the universities of Alcalá, Salamanca, Rome, and Coimbra. His *Defensio Fidei*, &c. (Coimbra, 1613), was in 1614 ordered by the parliament of Paris to be burned, because it claimed for the pope a coercive power over kings. In the same year and subsequently it was reprinted at Cologne. His complete works appeared at Lyons and Mentz (23 vols. fol., 1630 *et seq.;* new eds., Venice, 1740, and Besançon, 1856–'62). Francisco Noël prepared an abridged edition (2 vols. fol., Geneva, 1732; republished by J. P. Migne, Paris, 1858). The life of Suarez has been written in Latin by Deschamps (Perpignan, 1671), and in German by Werner (Ratisbon, 1861 *et seq.*).

**SUBLIMATION,** a process of distillation in which the vapors condense in a solid form. It takes place naturally in volcanic fissures and craters. Deposits thus formed are termed sublimates. A great variety of mineral substances are subject to vaporize by heat and become solid again on cooling; and the number of such increases with the increased degree of heat which we can apply. Some vegetable substances also possess the same property, as camphor and benzoin. Sublimation is much employed as a means of separating volatile from fixed bodies, usually for obtaining the former in a purer state. The vapor is sometimes chemically changed by contact with the oxygen of the air, and the sublimate is then of a different composition from the original body, as when oxide of zinc is produced by subjecting the metal or its ores to heat exposed to the air.

**SUBLIME PORTE** (Fr., lofty or magnificent gate; Turk. *babi humayun;* Ar. *ed-davlet el-aliye*), the title officially given to the Ottoman government. Orkhan (1326–'60) erected in his capital Brusa a palace with an imposing entrance, on which he bestowed the name of "Sublime Porte," which from that time to the present has been applied to the monarch and government of the Ottomans. This use of the term is partly owing to the oriental custom of transacting public business at the gate or in the antechamber of the palace.

**SUBPŒNA,** a judicial process directed to a witness commanding him to appear at the court, to testify what he knows in the case therein described, under a certain penalty (*sub pœna*) mentioned in the process. If the court wishes to examine any books or papers which are in possession of the witness, a clause is inserted bidding him to bring them with him; and the subpœna is thence called a *subpœna duces tecum.* The subpœna ought to be served upon the witness personally, for otherwise he cannot be proceeded against as for a contempt if he neglects to appear. Service may be made by any person, and is proved generally by affidavit, or, if it be made by a sheriff or his officer, by a simple return or certificate of service. When a witness has been duly summoned, and his fees have been paid or tendered, or payment or tender has been waived, he is guilty of a contempt of court if he fails to appear at the appointed time, and may be proceeded against by attachment, for the double purpose of compelling him to appear and testify, and of vindicating the dignity of the court by the infliction of suitable punishment. The party actually injured by the non-appearance may also have an action for all damages caused by his default.—The office of the subpœna at common law is simply to bring into court a witness whose evidence is sought. Chancery, borrowing the name of the writ, but giving it a far larger scope, issued it in order to compel a defendant in a cause to appear and answer upon oath the plaintiff's allegations. This process in chancery answers to a summons in the courts at law, and is the process by means of which the defendant is constructively brought before the court.

**SUBROGATION.** Where one person becomes entitled in law to the position of another as creditor or as the holder of securities, he is said to be subrogated to the rights of the other, and in contemplation of law there is a substitution or subrogation. When a surety pays the debt of his principal, he becomes subrogated to the rights of the creditor in any securities he may have held, with the right to enforce them for his own indemnity. So if one having a lien on property pays off a prior lien for the protection of his own, he becomes entitled to hold it against the interest of those who should have paid; and so would one tenant in common who should discharge a mortgage upon the whole title. The doctrine rests on principles of equity, and is one of very general application.

**SUBSCRIPTION,** in law, a contract by which one agrees to contribute with others for a common purpose. The word is sometimes applied to the sum of money subscribed. The contract

of subscription depends for its validity upon the same principles and facts as other contracts. The subscribers may be sued for their subscriptions whenever the conditions upon which they have promised to pay are fulfilled, if the purpose of the contract is legal and founded upon a good consideration, and if there is a party capable of maintaining the action. Subscription papers are often hastily drawn up and carelessly expressed, and the difficulty in the way of enforcing contracts of subscription has arisen chiefly from the want of proper parties and of a valid consideration for the promise. In their disposition to uphold this class of contracts, if they can be upheld consistently with the rules of law, the courts have gone in some cases so far as to say that the subscribers to a common object may be treated as contracting with each other, the consideration of each subscription being the promises of the other contributors, each subscriber being thus liable to a suit by all the others. There seems to be some difficulty in sustaining this view, and to avoid it subscriptions are usually made payable to some corporation or person who is to act as treasurer for the purpose of collection, and perhaps also in expending the moneys. Such undertakings, made on behalf of educational and charitable institutions or other public objects, or even for public celebrations, have frequently been sustained and enforced, and there seems to be no sufficient reason against such action. If by the subscription paper the promisee expressly undertakes to apply the moneys to the object in view, the case is clear; and certainly, if in any other case the subscription be accepted and acted upon by the expenditure of moneys or otherwise before notice that subscriptions are withdrawn, it should be held that this constitutes a consideration sufficient to support the promises, and that they cannot be withdrawn subsequently, but may be enforced. And such seems to be the tendency of decisions.

**SUCCINIC ACID,** an acid found ready formed in amber and in certain lignites, and occasionally in the animal organism. It may be obtained in colored crystals by heating amber in retorts. It is formed artificially in several ways, as by the action of hydriodic acid on malic acid or tartaric acid, or by the oxidation of certain fatty acids. It is most conveniently prepared by the fermentation of malic acid, the crude malate of calcium obtained by adding chalk or slaked lime to the juice of mountain ash berries being used for the purpose. The malate is mingled with water and yeast or decaying cheese, and kept for a few days at 86° or 100° F., when succinate of calcium forms. This salt is then decomposed by sulphuric acid, insoluble sulphate of lime being thrown down, while succinic acid is left in solution, and may be obtained by evaporation and cooling in colorless oblique rhombic prisms, soluble in five parts of cold and three parts of boiling water. The combinations of succinic acid with bases are called succinates, of which the most important are the calcium succinate above mentioned and succinate of ammonia. Succinic acid, though formerly officinal, is now seldom used in medicine. Succinate of ammonia is said to have been used with success in delirium tremens.

**SUCCORY.** See CHICCORY.

**SUCHET, Louis Gabriel,** duke of Albufera, a French soldier, born in Lyons, March 2, 1770, died in Marseilles, Jan. 3, 1826. He entered the army in 1792, was at the siege of Toulon in 1793 as chief of battalion, and was then transferred to the army of Italy. He was selected as one of the commanders in the army of Egypt, but was detained by Brune as major general in the army of Italy, in which he reëstablished order and discipline; afterward served as chief of staff under Masséna on the Danube, and again in Italy as general of division; and in 1800 distinguished himself in the defence of Genoa. In 1805 he commanded the left wing under Lannes at Austerlitz, and in 1806 took an important part in the battle of Jena. In 1808 he was made commander of a division in the army of Spain, and after successive victories he became marshal in 1811. He afterward took Oropesa and Murviedro, and defeated Blake near the lagoon of Albufera, under the walls of Valencia, and forced him to surrender that city, Jan. 9, 1812, with 18,000 Spanish troops and immense stores. For this victory he was rewarded with the title of duke of Albufera and a large revenue. He gained the esteem of the Spaniards by his justice and moderation. Louis XVIII. made him a peer in 1814. He wrote *Mémoires sur la guerre d'Espagne*, 1808-1814 (2 vols. 8vo, Paris, 1829).

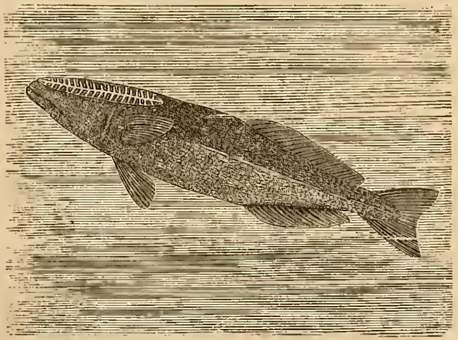
**SUCKER,** the popular name of the soft-rayed fishes of the carp family (*cyprinidæ*) included in the genus *catostomus* (Lesueur). They are characterized by a single dorsal, three rays in the gill membrane, smooth head and gill covers, jaws without teeth and retractile, mouth beneath the snout, and lips plaited or lobed suitable for sucking; there are comb-like teeth in the throat; the intestine is very long, and the air bladder divided into two or more parts. There are about 30 species in the fresh-water rivers and lakes of North America; they rarely take bait, and are very tenacious of life. The common sucker (*C. Bostoniensis*, Les.) is 8 to

Common Sucker (Catostomus Bostoniensis).

15 in. long, of a brownish color, olive on the head, reddish with metallic lustre on the sides, and white below; it is common in New England and the middle states. The chub sucker

(*C. gibbosus*, Les.) is 7 to 12 in. long, dark brown above, golden greenish yellow on the sides, anterior part of abdomen whitish, and fins dark; body convex in front of dorsal, and sides of head sometimes spiny or tuberculated; it is common in the ponds of the New England and middle states. Large species from the northern regions have been described by Richardson and Agassiz. Among the larger species of the western rivers are the Missouri sucker (*C. elongatus*, Les.), 2 to 3 ft. long, in the Ohio river, black on the back, and hence called black horse and black buffalo; and the buffalo sucker (*C. bubalus*, Raf.), of about the same size, in the Ohio, Mississippi, Missouri, and their tributaries, brownish above, bronzy on the sides, and whitish on abdomen.

**SUCKING FISH,** the popular name of the remora, a spiny-rayed fish of the genus *echeneis* (Linn.), so named from the Greek *ἔχειν*, to hold, and *ναῦς*, a ship. The body is elongated, tapering behind, covered with very small scales;



Mediterranean Sucking Fish (Echeneis remora).

there are four perfect branchiæ; very small teeth on jaws, vomer, and palate, crowded and hardly distinguishable posteriorly; mouth small and horizontal, the lower jaw the longer; eyes above the angles of the mouth; ventrals thoracic, narrow, united only at the base; head flattened. Above the head and anterior dorsal vertebræ is an oval disk, presenting from the middle to both sides oblique transverse cartilaginous plates, arranged like the slats of a Venetian blind; on the middle of the under surface are spine-like projections connected by short bands with the skull and vertebræ, and their upper margin is beset with fine teeth. According to De Blainville, this organ is an anterior dorsal fin, whose rays are split and expanded horizontally on each side instead of standing erect in the usual way. By means of this apparatus, partly suctorial and partly prehensile by the hooks, these fishes attach themselves to rocks, ships, and the bodies of other fishes, especially to sharks. The dorsal is opposite the anal, but the fins are weak, and these fishes accordingly adhere to sharks and other moving bodies, which transport them to places where food is abundant, and often from the tropics to temperate regions. There are six or eight pyloric appendages, but no air bladder. The common sucking fish of the Mediterranean, so well known to the ancients (*E. remora*, Linn.), is from 12 to 18 in. long, shaped somewhat like a herring, dusky brown above and lighter below; it has 17 or 18 plates on the head; it occurs in the Atlantic ocean, on the British coasts, and has even wandered to the American shores. The Indian remora (*E. naucrates*, Linn.) attains a length of 2½ ft.; it is olive-brown above and whitish on the sides, and has 22 to 24 plates in the sucking disk; it is found in the Atlantic, on the American and African coasts, in the Red sea, Indian ocean, and even around Japan. Peculiar to the American coast is the white-tailed remora (*E. albicauda*, Mitch.); it is from 1 to 2 ft. long, grayish slate above, with dark band on sides; the disk has 21 plates; it is not uncommon on the southern shore of Massachusetts and in Long Island sound, where it is generally called shark sucker. None of the species feed upon the fish to which they are attached, their food being small fishes and floating animals. (See LUMP FISH.)

**SUCKLING, Sir John,** an English poet, born at Whitton, Middlesex, in 1609, died in Paris probably in 1642. He was educated at Cambridge, inherited an immense fortune from his father, comptroller of the royal household, and in 1631–'2 served as a volunteer under Gustavus Adolphus. He was afterward a member of the court of Charles I., and in 1639 he equipped a body of 100 horse for the royal service, but was disgraced by pusillanimous conduct in an encounter with the Scots near Dunse. In 1640 he was elected to the long parliament; but having joined in a plot to rescue Strafford from the tower, he was compelled to take refuge in France. His literary remains include four plays, a number of short poems, chiefly amatory, and a treatise on "Religion by Reason." His works were published by Tonson in 1709, and in 1836 appeared "Selections from his Works," with a memoir by the Rev. Alfred Suckling. A new edition of his "Poems, Plays, and Remains" was published in London in 1874.

**SUCRE, or Chuquisaca,** the capital of Bolivia and of the department of Chuquisaca, on a plateau above the Rio de la Plata, about 10,000 ft. above the sea; lat. 19° 20′ S., lon. 65° 17′ W.; pop. in 1865, 26,664, the greater part of whom were Indians. It has regular, spacious, and clean streets, with well built houses, generally of two stories. The principal buildings are the cathedral, in the Moresque style, the president's palace, the churches of San Miguel and San Francisco, two monasteries, three nunneries, and the theatre. It is the see of an archbishop.

**SUCRE, Antonio José de,** a South American soldier, born in Cumaná, Venezuela, in 1793, assassinated near Pasto, Ecuador, in June, 1830. He joined the insurrectionary army in 1811,

and was made brigadier general in 1819, and soon afterward commander of a division. In May, 1822, he won the victory of Pichincha, which was followed by the capitulation of Quito. In 1823 he led a Colombian army of 3,000 men to Lima, which he found in the hands of the royalists, and retired to Callao, where he was besieged several weeks till the successes of Gen. Santa Cruz compelled the royalists to evacuate Lima. In 1824 he succeeded Bolivar in command of the liberating army, and on Dec. 9 won the crowning victory of Ayacucho. (See Ayacucho.) In 1825 Bolivia was created into an independent republic, and on Aug. 11 the constitutional assembly appointed Sucre president. In an insurrection in 1827 he was attacked and severely wounded. In 1828 Gen. Gamarra forced him to quit Bolivia. He went to Colombia, was made commander of the Colombian army of the south, and conducted a successful series of operations, which terminated in the defeat and capitulation of the Peruvians under Gen. La Mar at Tarqui, Feb. 26, 1829. In 1830 he was a member of the constituent congress, and was returning to Quito from a session of that body when he was assassinated.

**SUDERMANIA.** See Södermanland.

**SUDETIC MOUNTAINS.** See Germany, vol. vii., p. 744.

**SUDORIFICS.** See Diaphoretics.

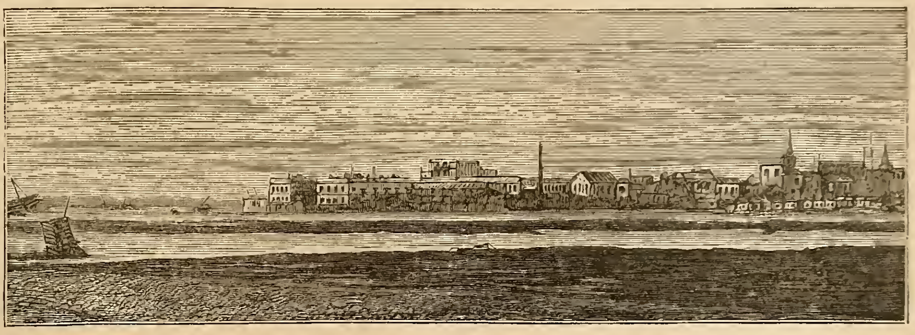
**SUE, Marie Joseph Eugène,** a French novelist, born in Paris, Dec. 10, 1804, died in Annecy, Aug. 3, 1857. He was an army and navy surgeon for several years till 1829, when he inherited a large fortune, and commenced writing maritime novels, of which *La Salamandre* (1832) attracted most attention. Under the patronage of the government he wrote *Histoire de la marine française au 17e siècle* (5 vols. 8vo, 1835–'7), which was a failure. In 1835 appeared *Cécile* and in 1841 *Mathilde*, two of his best novels, and in 1842 *Le morne au diable* and *Thérèse Dunoyer*. *Les mystères de Paris*, a work presenting terrible pictures of vice and corruption (10 vols., 1842–'3), and *Le Juif errant*, a merciless attack upon the Jesuits (10 vols., 1844–'5), had a prodigious circulation, and passed through many editions and translations. His other works include *Martin, l'enfant trouvé* (12 vols., 1847); *Les sept péchés capitaux* (16 vols., 1847–'9); and *Les mystères du peuple*, a narrative of the sufferings of a proletarian family through ages, which, after being continued serially from 1849 to 1856, was suppressed on account of its alleged immorality. He failed in 1848 as a candidate for the constituent assembly, but the socialistic tendencies of his most popular works gave him in 1850 a majority in a metropolitan district, and he was a silent member of the extreme left till the *coup d'état* of Dec. 2, 1851, which drove him from France. He afterward lived at Annecy, continuing his remarkable literary activity.

**SUETONIUS TRANQUILLUS, Caius,** a Roman historian, born about A. D. 72, died probably about 140. He was the son of a military tribune, and the younger Pliny helped him to become *magister epistolarum*. From this position he is said to have been removed by Hadrian about 121 in consequence of an indiscreet familiarity with the empress Sabina, though many historians entirely disbelieve the story, and give other causes for his dismissal. From the list of his works given by Suidas he must have been one of the most voluminous of Roman authors. His chief extant work is the *Vitæ XII Cæsarum*, in eight books, which abounds in details and anecdotes of a questionable character; besides which the treatises *De Illustribus Grammaticis* and *De Claris Rhetoribus*, and some brief biographies of Terence, Horace, Lucan, Juvenal, Persius, and Pliny the Elder, pass under his name. Fifteen editions of Suetonius's works had been published previous to 1500, of which the oldest with a date is that of Rome (fol., 1470). Among the best subsequent editions are those of Burmann (2 vols. 4to, Amsterdam, 1736) and Baumgarten-Crusius (Leipsic, 1816), revised by Hase (2 vols. 8vo, Paris, 1828), and newly edited by Roth (1858). All the fragments attributed to Suetonius have been published, with a critical commentary by Roth (1860). The first English translation was by Philemon Holland (fol., London, 1606), and the latest by Thomson and Forrester (Bohn's "Classical Library," 1855). On the sources from which Suetonius drew his facts, see Clason, *Tacitus und Sueton* (Breslau, 1871).

**SUEVI,** a powerful group of migratory German tribes, who about the beginning of the Christian era are said by ancient writers to have occupied the larger part of Germany. Cæsar describes them as dwelling between the Rhine and the Weser. According to Strabo, they extended across the central parts of modern Germany, between the Rhine and the Oder, and as far S. as the head waters of the Danube. Tacitus seems to designate by the name Suevi the tribes of eastern Germany from the Danube to the shores of the Baltic. In the 2d century the collective appellation disappears, the single tribes of the group being designated by their distinctive names. Later, however, other Suevi, an adventurous German people of mixed origin, appear upon the banks of the Neckar, where they gave rise to the modern name Swabia, and also in northern Spain, where they conquered Galicia early in the 5th century. Their Galician realm was destroyed by the Visigoths in 585.

**SUEZ. I.** An isthmus separating the Mediterranean and Red seas, and connecting the continents of Asia and Africa. From the most northerly part of the gulf of Suez in the Red sea to the gulf of Pelusium or Tineh in the Mediterranean the distance is a little more than 72 m.; on the line of the Suez canal it is about 100 m. The surface has a general elevation of only 5 to 8 ft. above the adjoining seas, but there are several ridges of from 20

to 65 ft., and a few depressions, lakes, and salt marshes which have become lakes since the construction of the canal. With the exception of places that have been made fertile by irrigation, it is a barren, sandy desert, uninhabited. Fresh water is found in but a few places. The surface soil is generally sand and gravel, underlaid with sandstone and varieties of limestone and conglomerate containing fossil remains and shells. It is probable that the whole isthmus was once under water, and that the Mediterranean and the Red sea were connected. Since the opening of the canal the climate has undergone a considerable amelioration, the temperature having become lower in summer and higher in winter. The change is attributed to the infiltration of water from the canal, and to the vegetation which has sprung up along its banks. (See CANAL.) **II.** A gulf forming the N. W. arm of the Red sea, lying between Egypt and the Sinai peninsula. It is about 180 m. long, and has an average breadth of 20 m. In ancient times it was called the Heroöpolite gulf. The Israelites are supposed to have crossed the Red sea on their exodus from Egypt a few miles below the head of the gulf. (See EXODUS, and RED SEA.) **III.** A town of Egypt, at the head of the gulf of Suez, 77 m. E. of Cairo; lat. 29° 57′ 30″ N., lon. 32° 35′ E.; pop. in 1872, 13,500, of whom 2,400 were foreigners. The old town is walled on the three landward sides, but open toward the sea. It stands on the border of a sandy plain where rain seldom falls, and previous to the opening of the fresh-water canal from the Nile in 1863 it depended for water on supplies brought from a distance. Suez was a mere fishing village until the building of the railway from Cairo, when it began to increase in size and importance; and the construction of the Suez canal, with its quays, docks, and other works, soon made it a large and busy place. The new quays and harbors, with the railway station and dry dock, are about 2 m. S. of the town, with which they are connected by railway. Among the principal buildings at Suez are the storehouses of the Peninsula and Oriental steamship company and of the *messageries maritimes*, the water works which supply the town from the fresh-water canal, the English hospital, and the chalet of the khedive on the heights overlooking the town and harbor. Suez is connected by railway with Cairo and Alexandria, but derives its principal importance from the Suez canal, of which it is the southern terminus. From the opening of the canal in November, 1869, to Dec. 31, 1874, 4,781 vessels, of 6,643,368 total tonnage, had passed through, of which 2,588 entered from the Mediterranean and 2,193 from the Red sea. Of the whole number, 3,286 were British, 394 French, 281 Austrian, 235 Italian, 121 Ottoman, 109 Dutch, 85 Egyptian, 83 German, 61 Spanish, and the remainder of other nationalities, only 8 being American. The number of passengers during the same period was 278,231, including 34,197 Moslem pilgrims and many troops of various nations. The total amount of tolls received during this time was 77,728,838 francs. In 1874, 1,264 vessels, of 2,421,803 gross tonnage, passed through the canal, of which 679 entered from the Mediterranean and 585 from the Red sea. The total receipts for tolls in 1874 were 24,748,900 francs. In November, 1875, all the shares of the Suez canal stock belonging to the khedive of Egypt, 177 out of 400, were purchased by the British government for £4,000,000. See *Lettres et documents pour servir à l'histoire du canal de Suez*, by Ferdinand de Lesseps (Paris, 1875).—Suez occupies probably the site of the ancient Clysma, the Kolzum of the Arabs. In the 8th century, after the destruction of the canal connecting with the Nile, it fell into decay. In the beginning of the 16th century it became a naval depot for the Turkish fleet in the Red sea, but soon lost its importance again with the decline of navigation in that sea in consequence of the discovery of the route to India by the cape of Good Hope.



Suez.

**SUFFOCATION.** See ASPHYXIA.

**SUFFOLK.** **I.** An E. county of Massachusetts, bordering on Massachusetts bay; area, about 44 sq. m. It comprises the cities of Boston and Chelsea and the towns of Revere and Winthrop. The population as returned

by the census of 1870 was 270,802; the subsequent annexation of the town of West Roxbury from Norfolk co. and the town of Brighton and city of Charlestown from Middlesex co. to Boston added 41,973 inhabitants, making the population within the present limits of Suffolk co. in 1870, 312,775; in 1875, according to the state census, 364,880. The number of manufacturing establishments, according to the census of 1870, was 2,546; number of hands employed, 43,550; amount of capital invested, $47,311,906; value of materials used during the year, $59,384,305; annual value of products, $111,380,840. Almost every variety of articles is produced. Capital, Boston, which is also the capital of the state. **II.** A S. E. county of New York, comprising the E. part of Long Island, bounded N. by Long Island sound and E. and S. by the Atlantic, drained by the Peconic river and several smaller streams, and traversed by the Long Island and other railroads; area, 1,200 sq. m.; pop. in 1875, 52,088. The surface is hilly and uneven in the north, but nearly level in the south; the soil is generally sandy, but fertile along the sound. The coast is indented by numerous harbors and inlets, and the county includes several small islands. The chief productions in 1870 were 184,564 bushels of wheat, 35,436 of rye, 515,099 of Indian corn, 322,069 of oats, 20,800 of buckwheat, 557,935 of potatoes, 43,006 tons of hay, 47,168 lbs. of wool, and 564,766 of butter. There were 7,112 horses, 9,269 milch cows, 9,704 other cattle, 14,412 sheep, and 12,624 swine; 6 manufactories of brick, 21 of carriages and wagons, 3 of cotton, 16 of fish oil, 3 of paper, 10 of saddlery and harness, 3 of sails, 12 flour mills, 1 woollen mill, and 19 ship yards. Capital, Riverhead.

**SUFFOLK**, a S. E. county of England, bordering on the counties of Norfolk, Cambridge, and Essex, and the North sea; area, 1,481 sq. m.; pop. in 1871, 348,479. The coast line extends about 50 m., and a great part of it is low and marshy. The principal streams are the Stour, Orwell, Lark, and Waveney; and there are several small lakes. The surface is undulating, with some flat and marshy tracts, and the soil is generally a rich alluvial loam. The manufactures, with the exception of agricultural implements, are trifling. Fishing is actively carried on. There are many remains of antiquity, including the Roman castle of Burgh, the walls of which are still standing. Suffolk contains two county towns, Ipswich and Bury St. Edmunds; other chief towns are Eye, Aldborough, Orford, and Sudbury.

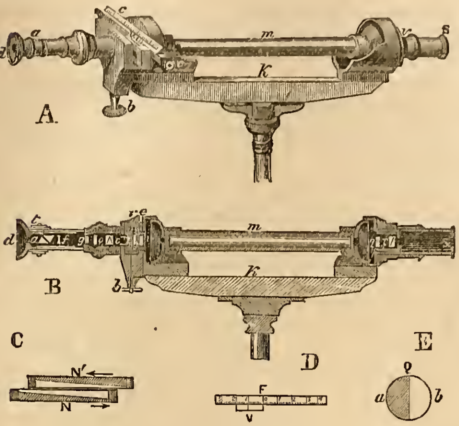
**SUFIS** (Arab. *suf*, wool, from the dress of the devotees), a peculiar sect of Mohammedans, who claim supernatural intercourse with the Supreme Being, a mystical identity and union with him, and miraculous powers. Said Abul Khair first gathered them into an organized body about 820, and they have numbered among them some of the most eminent Mohammedan scholars and poets.

**SUGAR**, a name used in nearly all languages, in various forms, to designate a limited number of sweet products of plants, which is made by the chemist to include several organic compounds, many of which may be artificially produced from similarly constituted organic bodies. Sugars are therefore divided into natural and artificial. In general terms they are now included among a group of compounds called hexatomic alcohols. Two of the natural sugars, mannite and dulcite, having the composition $C_6H_{14}O_6$, are saturated hexatomic alcohols, derived from the saturated hydrocarbon $C_6H_{14}$. Several others, called glucoses, have the formula $C_6H_{12}O_6$, and may be regarded as aldehydes of these alcohols. It may be remarked that ordinary glucose or grape sugar is converted into mannite by the action of nascent hydrogen, just as acetic aldehyde, $C_2H_4O$, is converted into common alcohol, $C_2H_6O$. There are also diglucosic alcohols, $C_{12}H_{22}O_{11}$, the most important of which are cane sugar and milk sugar.—Mannite, $C_6H_{14}O_6$, is the chief component of manna, an exudation from a species of ash. It is also found in several sea weeds and in mushrooms. It may be prepared by dissolving manna in boiling alcohol and filtering while hot. It crystallizes on cooling in tufts of slender, needle-like, four-sided prisms. It may be formed artificially by the action of sodium amalgam on glucose, the latter taking up two atoms of hydrogen. By oxidation with nitric acid mannite is converted into saccharic acid, $C_6H_{10}O_8$, and ultimately oxalic acid. The boiling point is 329° F. Dulcite, or dulcose, having the same formula, is obtained from a crystalline substance of unknown origin, imported from Madagascar, by boiling water. Crystals belonging to the monoclinic system form on cooling the solution. It thus differs from mannite, the crystals of which are trimetric, and also in its boiling point, which is 360°.—The glucoses are a group of sugars having the common formula $C_6H_{12}O_6$, and consisting, as far as known, of eight members: 1. Ordinary glucose or dextro-glucose, so named from its power of rotating a ray of polarized light to the right, is made by hydration of starch by the action of dilute acids or of diastase. It is found in honey and various fruits, especially grapes, and therefore also called grape sugar. (See FERMENTATION.) Its rotatory power is +56° at all temperatures. 2. Maltose is produced by the limited action of diastase on starch, and differs from ordinary glucose only in its power of rotating a ray of polarized light, having a dextro-rotatory power three times as great as that of ordinary glucose. It is converted into ordinary glucose by boiling with dilute acids. 3. Lævulose is isomeric with the others, but distinguished from them by turning the plane of polarization to the left. It also, unlike other sugars, has its rotatory power changed by varying the temperature, the power diminishing with increase of temperature, being −106°

at 57° F., —79·5° at 125·5° F., and —53° at 194° F. It occurs, associated with dextro-glucose, in honey and many fruits. A mixture of lævulose and dextro-glucose constitutes fruit sugar, fructose, or invert sugar, which is also lævo-rotatory, because the specific rotatory power of lævulose at ordinary temperature is greater than that of dextro-glucose. 4. Mannitose, produced by the oxidation of mannite, is uncrystallizable and fermentable, but has no action on polarized light. 5. Galactose, formed by the action of acids on milk sugar, crystallizes more readily than ordinary glucose, has a dextro-rotatory power of 83·3°, and is easily fermentable. 6. Inosite occurs in the muscular substance of the heart and other organs of the animal body, in green kidney beans, and in other plants. It forms prisms resembling gypsum, soluble in water, but insoluble in alcohol and ether. It does not ferment with yeast, but in contact with cheese, decaying flesh, or membrane, with chalk, it undergoes lactous fermentation, producing lactic, butyric, and carbonic acids. It has no optical rotatory power. 7. Sorbine occurs in the juice of the mountain ash berry. The juice on standing deposits brown crystalline matter, which by recrystallization forms crystals belonging to the trimetric system. It dissolves easily in water, and has a very sweet taste. It is converted by hot nitric acid into oxalic acid, and does not ferment with yeast, but like inosite undergoes lactous fermentation. It has a rotatory power of about −47°. 8. Eucalyne is found with other kinds of sugar in the so-called Australian manna, which falls in opaque drops from various species of eucalyptus. Its optical rotatory power is about +50°.—Besides these glucoses, there are sugars which may be regarded as formed by the combination of two or more molecules of glucose with the elimination of a number of molecules of water. These sugars have been called polyglucosic alcohols, having the formula $C_{12}H_{22}O_{11}$. 1. The most important member, as well as the most important of all the sugars, is cane sugar, or saccharose, which is found in the juice of many of the grasses and the sap of several forest trees, particularly the hard maple, in the roots of the beet, parsnip, mallow, and several other plants, and in most sweet fruits, associated with lævulose and dextro-glucose (currant sugar, fructose). Walnuts, hazelnuts, and almonds contain only cane sugar. Honey and the nectaries of flowers contain cane sugar together with invert sugar. Pure cane sugar separates from a solution by slow evaporation in large transparent colorless crystals, having the figure of a modified monoclinic prism. From hot saturated solutions it is obtained in masses of smaller crystals (loaf sugar). Its optical rotatory power is +73·8°; its sp. gr. 1·6, unchangeable in the air. When heated a little above 320° it is converted, without loss of weight, into a mixture of dextro-glucose and lævolusan, the anhydride of lævulose ($C_{12}H_{22}O_{11} = C_6H_{12}O_6 + C_6H_{10}O_5$ or lævolusan). It changes with loss of water into other substances as the temperature rises, until at 410° a brown substance called caramel is formed, which consists of a mixture of several compounds, all resulting from the elimination of the elements of water from sugar. As the temperature rises gases are evolved, consisting of carbonic oxide, marsh gas, and carbonic acid, and a distillate is obtained consisting of brown oils, acetic acid, acetone, and aldehyde, a quantity of charcoal remaining in the retort. By prolonged boiling with water, cane sugar is converted into invert sugar, the transformation being accelerated by the presence of acids, especially sulphuric. It is not directly fermentable, but by the action of yeast is resolved into dextrose and lævulose, which then enter into fermentation. It is a reducing agent, capable of readily taking the oxygen from several oxides and metallic salts. It forms with chlorate of potassium a mixture which detonates on percussion, and burns vividly in contact with oil of vitriol. It is distinguished from glucose by not turning brown when triturated with alkalies; but it combines with the alkalies, forming compounds called sucrates. 2. Parasaccharose, $C_{12}H_{22}O_{11}$, is produced by the spontaneous fermentation of a solution of cane sugar containing ammonium phosphate. Its rotatory power is +108°. 3. Melitose, $C_{12}H_{22}O_{11}$, is found in the Australian manna, associated with mannitose. The crystals which are deposited from the aqueous solution are hydrated, the formula being $C_{12}H_{22}O_{11} + 3H_2O$. At 212° F. they give off two molecules of water, and at 286° become anhydrous. Its rotatory power is +102°. Melitose ferments by the action of yeast, but is first resolved into glucose and eucalyne. 4. Melezitose, $C_{12}H_{22}O_{11}$, is a kind of sugar found in the so-called manna of Briançon, which exudes from the young shoots of the larch. It is not as easily acted on by reagents as the foregoing. Its rotatory power is about +94°. 5. Trehalose, $C_{12}H_{22}O_{11}$, $2H_2O$, is obtained from trehala manna, the produce of a species of *echinops* growing in the East. It forms rhombic crystals, which when heated below 212° F. slowly give off their molecules of water. Its rotatory power is +199°. With strong nitric acid it forms a detonating nitro-compound. It is not readily acted on by reagents. 6. Mycose, isomeric with trehalose, and also containing two molecules of water, is obtained from the ergot of rye by precipitating the aqueous extract of the fungus with basic acetate of lead, removing the lead from the filtrate by hydrosulphuric acid, evaporating to a sirup, and leaving the liquid to crystallize. Its rotatory power is +192·5°. 7. Milk sugar, or lactose, contains one molecule of water, the formula being $C_{12}H_{22}O_{11} + H_2O$. It is an important constituent of milk, and is obtained by evaporating the whey to a sirup, from which

on standing it separates in impure crystals, and may be purified by redissolving in water and filtering through animal charcoal. It forms white, translucent, four-sided, trimetric prisms of great hardness. It dissolves slowly in cold water, requiring five or six times its weight. Its optical rotatory power is $+59\cdot3°$. Very strong nitric acid converts milk sugar into nitro-lactine. It is brought very slowly into alcoholic fermentation by the action of yeast, but when cheese or rennet is used it is readily converted into lactic acid, alcohol being formed at the same time. A kind of sugar called glycyrrhizine or liquorice sugar, having the formula $C_{24}H_{36}O_9$, is found in liquorice root (*glycyrrhiza*). It has a peculiar sweet taste, but cannot be made to ferment. According to Gorup-Besanez, when boiled with dilute acids, it splits up into a resinous body called glycyrretine, $C_{18}H_{26}O_4$, and glucose.—*Saccharimetry.* There are various methods of estimating the proportion of sugar in a given solution, which are embraced under the generic term saccharimetry. They are usually employed for the estimation of cane sugar. There are four principal methods: 1, by the specific gravity of the solution; 2, by the amount of carbonic anhydride or of alcohol it will yield in fermentation; 3, by the amount of suboxide of copper precipitable from a solution by the action of grape sugar, into which the cane sugar present is first converted; 4, by the degree of rotation given to a beam of polarized light in passing through the solution. In the first and fourth methods instruments called saccharometers are employed, the term saccharimeter being often applied to the polarizing instrument. The specific gravity or hydrometric saccharometer is used by brewers for determining the amount of saccharine matter which has been produced in wort by the fermentation of malt. (See BREWING, and HYDROMETER.) The instrument is also employed by sugar makers and distillers. The brewer's saccharometer is usually graduated so as to indicate the excess of weight of 1,000 parts of a liquid by volume over that of the same volume of distilled water. For this purpose the hydrometer is marked 1000 upon its stem at the point to which it sinks in water, and with increasing numbers below this point. If the tested solution is dense enough to float the instrument till the number 1065 is at the surface, it is said to have a specific gravity of 65; if only to 1020, its gravity is said to be 20. Tables are used by which the quantity of sugar may be estimated from the specific gravity thus ascertained, and the tables may be adapted to differently graduated instruments, but the one above described (Baumé's) is usually employed. As beer wort holds other substances besides sugar in solution, the method is not exact, but in experienced hands it answers all the purposes of the brewer. When the solution is purely saccharine, or nearly so, as in clarified cane juice, the process is more nearly accurate; but when other substances are present the precise amount of sugar may be determined by the second method, that of producing fermentation and estimating the quantity of carbonic anhydride or of alcohol which is thereby formed. The third method, that by precipitation of suboxide of copper from an alkaline solution of tartrate of copper and potash, is briefly as follows: A standard solution, known as Fehling's, is prepared with 1 oz. of crystallized sulphate of copper, 3 oz. of bitartrate of potash, $\frac{1}{2}$ oz. of pure carbonate of potash, and 14 or 16 oz. of a solution of caustic potash of sp. gr. 1·12, with sufficient water to make the solution weigh 15,160 grs.; 200 grs. of this solution contain an amount of copper which is completely precipitated by 1 gr. of grape sugar. In using Fehling's solution a temperature approaching the boiling point should be maintained, and the saccharine solution should be slowly added from a graduated burette. It is necessary before testing to convert the cane sugar into glucose, which is done by adding sulphuric acid and boiling. The method by polarized light is performed by employing an instrument first devised by Biot, but since modified and improved by Soleil. In the article LIGHT, vol. x., pp. 449, 450, it is shown that several substances have the property of rotating the plane of a polarized ray, some to the right and some to the left, and also that substances having the same chemical composition may rotate the ray in both directions. A solution of dextrose (grape sugar or glucose) has the property of right-handed rotation, while lævulose, having the same chemical composition ($C_6H_{12}O_6$), turns the plane of polarization to the left. Quartz also, by reason of a difference in its molecular structure, is in some specimens right-handed and in others left-handed in its power of rotation. The original apparatus devised by Biot employed a tube containing the solution of sugar to be examined, the depth of the liquid producing a certain degree of rotation indicating the proportion of glucose it contained, and therefore the amount of cane sugar, this being first converted into glucose. The saccharimeter devised by M. Soleil does not measure the degree of rotation produced directly, as in Biot's instrument, but employs the principle of compensation, and furthermore employs a comparison of color, using therefore white instead of homogeneous light. The amount of compensation is measured by an attachment called a compensator, which is made of two wedge-shaped pieces of quartz whose combined thickness may be varied by sliding them over each other. A copper tube, *m*, figs. A and B, tinned on the inside and containing the solution to be tested, is closed at both ends by two glass plates, and rests upon the support *k*, which also bears at its ends the tubes *a* and *r*. These tubes contain the analyzers and polarizers, which are represented in section at B. The light of a com-

mon lamp is passed through the aperture S and the double-refracting prism $r$, the polarizer which transmits the ordinary ray, the extraordinary being thrown out of the field of vision. (See LIGHT, vol. x., pp. 445, 446.) The prism is so placed that the plane of polarization is in the axis of the instrument and also vertical. After passing through the double-refracting prism the polarized ray meets a refracting plate $q$, shown in section at E, composed of two pieces of quartz placed side by side, one having right-handed and the other left-handed polarizing powers. These plates are each 3·75 millimetres thick, producing a rotation of 90° and a rose-violet tint, called the transition tint. These two quartz plates, having equal powers of rotation, turn the ray in opposite directions, and therefore when viewed through a double-refracting prism they appear of the same tint when the plane of the ray is perpendicular; but if it has been turned by passing through a rotating solution, a difference of tint will be produced. After passing through the double quartz plate $q$, the ray traverses the solution in the tube $m$, and a single quartz plate $i$, fig. B, of any thickness and either right-handed or left-handed. The compensator $n$, composed of two wedge-shaped pieces of quartz, shown in section at C, both either right-handed or left-handed, but of opposite rotation to the plate $i$, is next traversed by the ray. This compensator can be varied in thickness and therefore in rotating power so as to balance exactly the degree of rotation produced by the solution. Its thickness is regulated by means of a rackwork and pinion turned by the milled head screw $b$, figs. A and B. A scale and vernier shown at D is affixed to the plates, by which the thickness of the compensation may be read, the vernier pointing to zero when the thickness of the two plates is equal to that of $i$. A double-refracting prism $c$, fig. B, is placed next behind the compensator to act as an analyzer which has been



Soleil's Saccharimeter.

acted upon by the solution and the various plates. When the liquid in the tube is inactive and the compensator is not at zero, the plate $i$ and the compensator will neutralize each other's effect, and the two parts of the double quartz $q$ will have the same tint; but when the tube $m$ contains a solution having a rotatory power, like sugar, this power added to that of one of the plates will rotate the plane of polarization of the transmitted ray either to the right or to the left. If the solution contains cane sugar or dextrose, or a certain excess of either, it will rotate it to the right; if it contains lævulose or a certain excess, it will rotate it to the left, and therefore a difference in tint will be observed in the two halves of the double quartz plate $q$, one half perhaps being red and the other blue. The thickness of the compensator is then adjusted by turning the milled head $b$ until the tints become the same, and the increase or decrease in the thickness of the two plates will indicate the rotatory power of the solution, either right-handed or left-handed, and may be read upon the scale. The following standard of comparison is employed: If 16·471 grs. of pure cane sugar is dissolved in sufficient water to make 100 cubic centimetres, this solution placed in a tube 20 centimetres long will produce the same degree of rotation as a right-handed quartz plate one millimetre thick. Or if a tube exactly 37·65 in. long is filled with a solution containing 10 per cent. of pure cane sugar (crystallized sugar candy), and a polarized ray from the middle of the yellow band of the spectrum is passed through it, the rotation of the plane will be 73·8°. This, compared to the rotation produced by a solution of pure cane sugar of a different strength, will show the relative proportion it contains; or if the depth of the solution is less, the rotation will be less in the same proportion. If the solution contains left-handed sugar, the result will be vitiated and corrections have to be made. This may be done by converting all the sugar into left-handed sugar by the action of hydrochloric acid, and making a second observation, when by a comparison of the results obtained at both observations the amount of cane sugar may be estimated. The optical rotatory power of the various sugars mentioned in this article has been determined according to the standard of comparison here given. The arrangement of prisms and lenses placed behind the double-refracting prism $c$ forms what M. Soleil calls the producer of sensible tints. The particular tint which allows the most delicate difference in the color of the two halves of the double quartz to be distinguished is not the same for all eyes. This effect is produced by placing in front of the prism $c$ a quartz plate $o$ cut perpendicular to the axis, then a small Galilean telescope, consisting of a double convex lens $g$ and a double concave lens $f$, with adjustable focal distance. The double-refracting prism $c$ acts as polarizer to the quartz $o$, while the prism $a$ is the analyzer, and on being

turned to the right or left may be made to produce that tint to which the eye of the observer is the most sensitive.—*Sugar Cane.* Commercial cane sugar is made from species of *saccharum*, especially *S. officinarum*, a genus of grasses of the tribe *andropogoneæ*, of which subdivision the cultivated sorghum and broom corn are familiar examples. Sugar cane is a perennial grass, with solid stems from 6 to 20 ft. high, the older plants throwing up numerous stems or suckers from the root; the leaves, 3 ft. or more long and 3 in. broad, have thin sheaths, usually glaucous with a bloom or waxy exudation, which is also found upon the stem, especially in the dark-colored varieties; the flowers are in a large, ample, and showy panicle, about 2 ft. long, the ultimate branches of which are notched or jointed, bearing at each joint two flowers, one of which is sessile and neutral, the other on a short pedicel and perfect; both kinds of flowers are surrounded

Sugar Cane (Saccharum officinale).

by a tuft of long hairs, which gives the cluster a soft silvery appearance. The sap or juice of the plant contains from 15 to 20 per cent. of sugar. It has not been found in the wild state in any part of the world; and while there is much doubt as to its native country, the most careful investigations point to Bengal as the origin of *S. officinarum*, and it was there that the manufacture of sugar commenced. If, as botanists are disposed to admit, the sugar cane of China is a distinct species (*S. Sinense*), it would appear that the cultivation of related plants for the extraction of sugar was undertaken separately in two distinct and widely separated countries. While the product was anciently referred to as "honey of canes," and by other names, sugar as we know it is not mentioned before the commencement of the present era. Dioscorides, about A. D. 100, mentions *saccharon.* In the 9th century the cultivation had extended to Persia, and in the 10th and 11th centuries Avicenna and other eastern physicians used sugar in medicine. Its cultivation was carried on in Spain in the 10th century, at which time sugar was an article of trade, especially by the Venetians, through whom the English received their supply. The cane was introduced into Madeira in 1420, and some time after into the Canaries. With the discovery of America, its distribution was very rapid, Santo Domingo, Brazil, Mexico, Guadeloupe, and other countries undertaking its culture in quick succession. Meanwhile it spread to Africa and the Indian archipelago. In 1852 it was taken to New South Wales; it had long previously been cultivated in most of the islands of the Pacific. Several early writers mention the sugar cane as one of the indigenous products of the United States, and it was said to grow in Virginia and in Louisiana; of course some other large grass was mistaken for the sugar cane; both the common reed (*phragmites*) and the southern cane (*arundinaria*) have a sufficiently near resemblance to sugar cane to lead a careless observer into this error. The plant appears to have been cultivated in this country for the first time about 1751, near the site of New Orleans, by some Jesuits from Santo Domingo. In 1758 the first sugar mill was built, a little further down the river, by M. Dubreuil. According to a statement of E. J. Forstall in De Bow's "Industrial Resources," vol. iii., p. 275, the manufacture of cane into sugar does not seem to have commenced before 1764; but sugar is said to have been one of the staple products of the colony in 1770. After the revolutionary war it was prosecuted so successfully by emigrants from the United States that in 1803 there were 81 sugar estates on the Mississippi delta alone. The cession of Louisiana to Spain seems to have arrested the industry, as no accounts of sugar making are found until 1791, when the first sugar house under the Spanish government was erected by a Mr. Solis at Terre aux Bœufs, in the parish of St. Bernard. The next was established in 1796 on a plantation where now stands Carrollton. The success of this enterprise was the foundation of the sugar culture in Louisiana. In 1818 the production was 25,000 hogsheads, and the cane was ground altogether by cattle, steam power not being introduced till 1822. The sugar-growing district in Louisiana is on both sides of the Mississippi, from 57 m. below New Orleans to nearly 190 m. above; on the Red river and its tributaries; and on many of the bayous. But even Louisiana is rather too far north to allow of the perfect ripening of the plant, which is sometimes killed by the frost in the spring, and also injured in October and November. In Texas the crop is important, and cane is grown to a considerable extent in several of the other gulf states, especially in Florida, and to a limited extent in South Carolina, Tennessee, and Kentucky. In the more northern localities it is profitably cultivated mainly for

the manufacture of sirup.—It is not definitely settled whether the sugar cane from China (*S. Sinense*) is really a distinct species, but all others formerly so regarded are now considered as only forms of *S. saccharatum*, of which each sugar-growing country has several varieties. The country or creole cane, the kind first introduced into the West Indies and Louisiana, and regarded as the original form of the species, was at one time much esteemed, but has greatly deteriorated. The ribbon cane, so called from the yellow and purple stripes upon the stem, is inferior to the following varieties. The Otaheite or Bourbon cane was introduced into Georgia in 1805, and is also a favorite variety in some parts of the West Indies, its stem being thicker than that of the others. It has been supposed that this was a native of Otaheite or Tahiti. The violet or Batavian cane has a purple stem, varying in depth of color with the nature of the soil; its leaves are luxuriant and of a dark green color, and the flowers are purplish; it has been described as a distinct species, *S. violaceum*, but there is nothing to warrant its separation from the ordinary cane. Besides these leading varieties, there are the claret, imperial, Mont Blanc, and others, with numerous local subvarieties. The dark-colored canes are found to resist the attacks of disease much better than the light-colored ones, a peculiarity of which there are numerous other illustrations among plants and animals.—In none of the sugar-producing countries does the sugar cane ever perfect seeds, and it is quoted as an illustration of the fact that plants which have long been propagated by other methods lose the power of producing seeds. The cane is always propagated by cuttings, and as the lower portion of the stem is the richest in sugar, the upper and comparatively worthless portions are used for cuttings, a practice to which the deterioration of varieties is ascribed. The details of cultivation vary in different countries; in the cooler cane regions there is a season when growth must cease, while in others it is continuous; in some prolonged rains modify the culture, and in others irrigation must supply the needed moisture. But wherever it is grown, it must have a fertile soil; it is a plant which quickly exhausts the soil, and unless manure is used, the land is fallowed, or the crop forms part of a rotation, the soil is soon run down. In some sugar-growing countries the ground is prepared by penning cattle upon the fields; in others some crop is grown which, with the weeds, is turned under; and in the British West Indies fertilizers of various kinds are used. The distance between the rows varies from 2½ to 8 ft., the latter distance giving a better crop than closer rows. In the best culture the land is well ploughed, and then thrown up into ridges with the plough, at the desired distance apart; a trench, 3 in. or more deep, is opened upon the top of the ridge, in which the cuttings, about 2 ft. long, are laid in a single and sometimes a double row; the cane is then covered by hoes, or by a cane coverer drawn by horses, which will cover 10 acres in a day. After the shoots appear they are kept clear of weeds until they shade the ground, and prevent all other growth. In dry countries it is customary to "trash" the cane when it gains a sufficient size; the lower leaves are broken off and laid upon the earth to prevent evaporation. The shoots produced the first year from the cuttings are called "plant canes;" it is known to have attained its full growth by "arrowing;" the lower joints are usually about 3 in. long, but above they increase in length while they diminish in diameter and are much less rich in sugar, until finally a long joint (in tropical countries 6 or 8 ft. long) shoots up, which if permitted would bear the flower cluster; this shoot is termed the "arrow," and its appearance indicates that the cane should be topped, or cut up at once, else the accumulated sugar in the juices of the plant would be expended in the production of flowers. In climates where the season is short the cane does not arrow, and the time for cutting is governed by the probable appearance of frost. In Louisiana it begins to ripen at the bottom in August; as each joint ripens the leaf belonging to it withers, and when it is time to harvest the upper part of the cane is cut back to a joint upon which the leaf is dry, and the crop is cut off close to the ground; if frost is apprehended, the cane is "mattressed," the product of three rows being so laid together that the leaves of one armful will cover the buts of the preceding; being thus thatched, the canes are protected from frost and will keep in this state for several weeks without injury. The second year after planting numerous shoots start up from the old plants; these are called "rattoons" (Fr. *rejetons*), and the crop is thereafter a rattoon crop, the value of which, though less than that of the plant cane, depends upon the original fertility of the soil, or the manner in which this has been maintained. In Louisiana but one or two rattoon crops are taken, requiring a replanting every second or third year; while in some of the West Indies the plantation lasts from six to ten years, and in the East even longer; but when thus long continued, the yield is small and the impoverishment of the soil correspondingly great. —*Manufacture of Cane Sugar.* As soon as the canes are cut they are ground in a mill. There are many forms of mills, and those in use in the East Indies from the earliest times are exceedingly rude, slow, and inefficient, and very rude mills are still used by small planters in the West Indies; but powerful mills driven by steam are employed upon the larger estates, the crushing apparatus usually consisting of three heavy cast-iron rollers. The canes are usually passed twice through the mill. About two thirds of all the juice is extracted, and the crude liquor contains, besides sugar, woody fibre, soluble salts, albumen,

caseine, wax, &c. In the hot climate of the sugar plantations the juice if left to itself begins to ferment in the course of an hour; it is therefore immediately treated with from $\frac{1}{3000}$ to $\frac{1}{800}$ of its weight of lime, and heated to 140° in large flat-bottomed copper pans or clarifiers holding from 300 to 400 gallons each. This coagulates the albuminous portions, which rise to the surface as scum. Some planters treat the juice with sulphurous acid, by which fermentation is delayed. The clear liquid, after cooling for an hour or two, is drawn off for concentration by boiling. The fuel used is usually the dried crushed canes, the ashes of which are returned to the soil. By the old method practised in Asia a series of 11 kettles or earthen boilers is set in a line in a rudely constructed range, at one end of which is the fire, with a large iron boiler over it, and at the other the chimney. The juice is first put into the boiler furthest from the fire, and is gradually transferred to the others, as the process goes on, until the final concentration is effected in the iron boiler. The product is afterward drained and the sugar is clarified by boiling again with water, an alkaline lye, and milk. A somewhat similar arrangement of kettles, to the number of four, five, or six, has been employed in this country and the West Indies, each kettle having its own fire, and the defecation or partial purifying being effected during the boiling by "tempering" the liquor with slaked lime. This, when used in small quantity, causes the glutinous matters present to coagulate and rise upon the surface in a scum, which may be continually removed by skimming. It also neutralizes any acid that may have formed. In Louisiana it has been the practice to concentrate the sirup to 42° Baumé in the last kettle, called the battery, and then transfer it to large wooden vats, called coolers, for granulation; but the operations have been variously modified there, and different methods too have been pursued in the West Indies. Instead of kettles, each one requiring a separate fire, large copper caldrons are heated by steam, either by being enclosed in a steam jacket or by containing a coil of steam pipe. The clarification is effected as before by means of lime added to the sirup diffused through a portion of juice, or in the form of milk of lime of known strength and carefully graduated, so that exact quantities may be used. Just enough should be used to neutralize exactly the sirup, which may be known when litmus paper indicates neither an acid nor alkaline reaction. An excess of lime should be particularly guarded against, as it involves a loss of sugar; and when it occurs the effect should be corrected by careful addition of alum, or better of sulphate of alumina, which contains no potash. The heat employed in clarifying should not reach the boiling point of the sirup. At a less degree a scum gathers upon the surface, and when this breaks up into white froth, the clarification is completed. The heat is then stopped, and the liquor is left to repose for an hour, when it is drawn away from the scum, and is seen as it flows into the first of the evaporating pans to be of a clear bright wine-yellow color. These pans, to the number of three or more, are set in succession over a flue heated by a fire at one end. The liquor is gradually transferred to the smaller pans, and as it boils away the scum that rises is taken off. It is the skimmings in these operations that furnish the best materials for distillation, and the manufacture of rum is very generally carried on in connection with that of sugar. In the smallest and last pan, to which sometimes the term "teache" is exclusively applied, the sirup is finally collected; and when it is judged to be sufficiently concentrated for granulating, it is transferred into the coolers, and thence into the vessels, also called coolers, in which the granulating takes place. These are of wood with thick sides, about 7 ft. in length, 5 or 6 ft. in width, and not less than a foot deep. This depth and the thick sides are requisite to secure slow cooling, without which the grains could not be coarse. In about 24 hours the graining takes place, the crystals forming a soft mass in the midst of the liquid portion or molasses. The separation of the two products is effected by drainage in what is called the curing house. This is a large building covering an open reservoir. Frames are provided for hogsheads so that the drippings from these shall flow into the reservoir. In the bottom of each hogshead several holes are bored, and into each hole is put a crushed cane or the stalk of a plantain leaf, the lower end projecting several inches below the bottom. The hogsheads being filled with the soft sugary mixture, the molasses gradually drains away from it, dripping from the stalks. The operation goes on for three to six weeks, till the sugar is considered sufficiently dry for shipping. It still retains considerable molasses, and in the moist hold of the ship the separation continues, the molasses leaking away and involving a serious loss. The "Julius Robert diffusion process" for extracting sugar from cane is in use at the sugar establishment of Messrs. Koch, in Bayou Lafourche, Louisiana. A series of tall cylinders connected by pipes are filled with thinly sliced canes and water. The diffusion allows the hydraulic pressure to carry off the dissolved sugar. The water is heated by steam to about 190° by a boiler through which the diffusion juice passes. It is said that a much greater proportion of the sugar is extracted by this method, and that the clarifying process is much simplified and abridged.—*Sugar Refining.* The preparation of the purest varieties of sugar did not originate in the sugar-producing countries, but the art was applied first by the Venetians to the crude sugars brought from Egypt. It was practised in Antwerp in the 16th century, and was thence introduced into England. At present it is an important branch of manufacture

in most of the principal commercial cities of the United States and of Europe. As formerly practised, raw sugar was dissolved with lime water in a large open boiler, and, when warm, bullock's blood was added, which as it coagulated on boiling collected most of the lighter impurities and carried them to the surface in the form of a thick scum. This being removed, the liquor was partially evaporated by boiling, filtered through woollen cloth, then concentrated and grained on the general plan already described. The best sugar refiners do not now use blood or any other coagulating substance to collect suspended matters, but separate them entirely by filtration. The process in the best establishments is substantially as follows: On the ground floor the raw sugar is dissolved in hot water in large cisterns. Water enough is added to produce a specific gravity of about 1·25, or 29° Baumé. By a large pump near each cistern at the same level the solution is drawn off through a connecting pipe provided with a coarse wire strainer, which prevents all except the smaller solid particles from entering the pump. The saccharine solution is pumped up into the highest story, which is usually the seventh or eighth, it being cheaper as well as more convenient to elevate the sugar in solution than in a solid state. It is pumped into vessels called "blow-up pans," because steam was formerly blown into them to heat them. They are now heated with close coils to about 208° or 210° F. Milk of lime is added to the solution in these pans for the purpose of neutralizing any acid which it may contain. From these pans the sirup passes down to the next floor and into filters by which it is completely deprived of all suspended solid particles. These filters consist of a great number of bags 4 or 5 in. in diameter and 8 or 10 ft. long, made of two thicknesses of cloth, an outer of coarse and an inner of fine material. They are enclosed in sets of about 200, in boxes, to prevent cooling. After a time they become foul, when they are turned inside out and washed. After leaving the bag filters, which it does at a temperature of from 170° to 180°, the sirup is run through filters of animal charcoal or bone black. These are immense cylinders, 6 or 8 ft. in diameter and usually from 20 to 25 ft. high, filled with pulverized bone black, which substance has the property of absorbing all the coloring matter in the sirup, which runs from the bag filters of a sherry wine color. After a time the charcoal becomes foul and loses its property of absorbing coloring matter, when it is taken to a neighboring room and reburned in kilns. The sirup which runs from the charcoal filters at a temperature of about 150°, and, in a perfectly colorless condition, is now pumped into vacuum pans and concentrated to the granulating or crystallizing point. These vacuum pans were invented by Howard and patented in 1812. They are large conical or ovoid vessels heated by steam and exhausted with air pumps, by which the air and vapor are rapidly removed. In the later stages of the process the pressure is reduced to only 3 in. or less of mercury. The pans are sometimes supplied with an apparatus for condensing the steam by a cold spray. In making hard sugars, at the commencement the evaporation is conducted at a temperature of 170° to 180° F., but as soon as granulation begins it is lowered to 160°, and just before the evaporation is completed it is reduced to 140°, this being the lowest temperature at which crystallizing sugar boils at a pressure of 3 in. of mercury. An ingeniously devised sliding tube, by which a "proof" may be taken without admitting air, is attached to the vacuum pan. In making soft sugar the temperature is kept rather lower. As soon as crystallization begins the sugar is run off, and if it is to be made into soft sugar, the sirup is discharged by means of centrifugal mills. If it is for hard sugar, it is run into a vat which has a gate in its bottom; from this it is run into conical moulds placed upon carriages, which are drawn under the gate. In the bottom of each mould there is an orifice which is kept closed by a stopper for several hours, until the sugar crystallizes, when it is removed and the sirup allowed to drain away. The loaf which remains has a slight yellow tint, which is removed by allowing a colorless solution of sugar to pass through it. The loaves are then taken out of the moulds and dried in ovens at a temperature of about 160°. The sirup which drains from the moulds still contains a small percentage of cane sugar, but too small to recover with profit. It is therefore sold as sirup. It may be here remarked that raw molasses contains enough cane sugar to make it profitable for some establishments to make a specialty of extracting it. The muscovado molasses from Cuba, Porto Rico, and Antigua is esteemed the best.—*Beet Sugar*. In 1747 Marggraf, a Berlin chemist, found that the white beet yielded 6·2 per cent. and the red beet 4·6 per cent. of sugar, but the manufacture was not developed till the close of the year 1800. (See Beet.) The beets preferred in Europe for the manufacture of sugar are varieties of the white Silesian, yielding a juice richer in sugar and more free from salts than that of other kinds of beet. The weight of the larger ones is about 5 lbs. each; and the yield per acre in France and Belgium is 14 or 15 tons, and about Magdeburg 10 to 12 tons of beets. The crop is successful over the greater part of Europe, but more particularly N. of lat. 45°, and upon light dry soils, in a dry atmosphere. The richness of the juice is injured by direct application of manures to the growing crop, and it is less in large beets than in small ones. When the leaves begin to die, the beets are dug, the heads cut off, and the roots are thrown together and covered to protect them from light and frost. They may be thus kept for some time, though there is always risk of portions of the sugar passing

into the uncrystallizable variety. The proportion of sugar contained in the fresh root varies from 5 to 12 per cent., and the product in a large way is usually about 6 per cent., sometimes 7½. The other contents of the root are: water, 83 to 94 per cent.; ligneous fibre and albumen, 2·5 to 5 per cent.; together with a small proportion of what is supposed to be pectine, and a trace of mineral substances. In the factory the beets are first washed clean in a cage revolving on a horizontal axis, and partly immersed in water; and when washed they are discharged by the action of the machine itself. As the juice cannot be forced out from the cells by compression alone, it is found necessary to tear open the cellular tissue, and this is done by a grating machine of the form of a rotating drum, the inner surface of which is studded with teeth. The pulp is then subjected to powerful hydraulic pressure. Maceration has also been employed to separate the juice. For this purpose the beets are cut into thin slices and put into a cistern with about their own bulk of hot water. In half an hour the liquor is let down upon other slices in another cistern, and so on through three to five vessels, until it acquires a density of 5½° to 7° B. By this process the juice is rendered very weak and apt to ferment, and requires much fuel to concentrate it. Perhaps the best method is to expel the juice by centrifugal force. Another method practised near Heidelberg is, as soon as the beets are gathered and washed, to cut them into small rectangular pieces and dry them upon floors. Their bulk is thus reduced about 84 per cent., leaving 16 of dry matter, which may be kept for any time and transported to any distance. The sugar is then extracted by infusion or by maceration through a long series of vessels. The factory where this operation is carried on at Waghäusel is of immense extent, the buildings, formerly a Benedictine monastery, covering 12 acres of land. The infusing vessels, 20 in number, are 12 to 14 ft. deep and 7 ft. wide. The beets when dried produce about 46 per cent. of sugar. The juice, however obtained, is rendered alkaline by the addition of lime water, and is then boiled. Excess of lime is removed by the chemical process of converting it into carbonate by passing a current of carbonic acid gas into it, which may be generated by a coke furnace according to the method proposed by Barruel of Paris in 1811, or the gas may be generated by the action of sulphuric acid on chalk, as since proposed by Michaelis. This process is called de-liming, and it may also be effected by filtering the solution through animal charcoal. Several other methods have been employed or proposed. Dubrunfaut and Massey patented a method with caustic baryta, which forms with cane sugar at the boiling point an insoluble saccharate, $C_{12}H_{22}O_{11},BaO$, sufficient baryta being used to throw down all the sugar. The supernatant fluid, which contains all the impurities, is then run off, when the sugar is recovered by treating with carbonic acid, by which the baryta is withdrawn in the form of insoluble carbonate, the sugar dissolving. The subsequent processes of filtration, concentration, and granulation are similar to those already described. The manufacture of beet sugar has been attempted in the United States, but as yet with little success except in California, where it promises to become an important industry. (See CALIFORNIA, vol. iii., p. 605.)—*Maple Sugar.* Several species of the maple afford, when the sap begins to flow in the spring, a juice containing crystallizable sugar. That yielding the richest juice is the *acer saccharinum*, the rock or sugar maple. The swamp or river maple, known also as the white or soft maple, produces a juice of inferior quality, but which is sometimes employed in sugar making. The manufacture is said to have originated in New England about the year 1752. It thence extended throughout the wooded portions of the country where the sugar maple abounds, particularly New York, Michigan, Pennsylvania, and Ohio, and on the range of the Alleghanies further south. It is carried on in Canada both by whites and Indians. (See MAPLE.)—*Production and Trade.* Louisiana produces the great bulk of the cane sugar crop of the United States, and is the only state which exports sugar, the other cane-growing states producing scarcely sufficient for local consumption. The product of Louisiana from 1860 to 1873 is given under LOUISIANA. The crop of 1874 is estimated at 125,000 hhds., and of 1875 at 135,000 hhds. The total exports of sugar from Havana and Matanzas from Jan. 1 to Nov. 23, 1875, were 1,018,296 boxes, 249,331 hhds., or 332,105 tons, of which 344,187 boxes, 204,061 hhds., or 184,455 tons went to the United States. The imports of sugar from all sources, from Jan. 1 to Dec. 1, 1875, were: at New York, 408,981 tons; Boston, 111,192 tons; Philadelphia, 34,630 tons; Baltimore, 63,141 tons; total for the Atlantic coast, 617,944 tons, against 611,124 tons in 1874, and 598,995 tons in 1873, or an average of 609,354 tons for three years. The imports at San Francisco from Jan. 1 to Oct. 1, 1875, were: from Manila, 10,503 tons; Hawaiian islands, 6,679 tons; China, 2,038 tons; Central America, 324 tons; total, 19,544 tons, against 27,438 tons in 1874, and 21,132 tons in 1873, or an average of 22,705 tons for three years. The consumption of cane sugar on the Atlantic coast in 1874 was 710,369 tons; on the Pacific coast, 30,046 tons; of sugar made from molasses, 43,600 tons; of maple sugar, 15,000 tons; total, 799,015 tons, against 738,525 tons in 1873, and 720,873 tons in 1872, an increase in 1874 of 8 per cent. over 1873, and 11 per cent. over 1872. In nine months ending Sept. 30, 1875, the Atlantic ports exported of refined sugar 13,688 tons, against 3,030 tons in 1874, and 3,412 tons in 1873. The imports at the principal European depots in 1873, 1874, and for nine months

ending Sept. 30, 1875, are shown in the following table:

| DEPOTS. | | IMPORTS. | | |
|---|---|---|---|---|
| | | 1873. | 1874. | 1875. |
| Holland | tons. | 77,400 | 82,850 | 46,750 |
| Antwerp | " | 6,130 | 8,540 | 9,580 |
| Hamburg | " | 84,700 | 85,000 | 17,000 |
| France | " | 157,033 | 136,542 | 180,000 |
| Bremen | " | 980 | 1,890 | 8,840 |
| Trieste | " | 7,950 | 9,730 | 9,330 |
| Genoa | " | 18,900 | 21,000 | 17,500 |
| On the continent | " | 303,093 | 295,552 | 284,000 |
| In Great Britain | " | 653,588 | 676,488 | 760,652 |
| Total | " | 956,681 | 972,040 | 1,044,652 |

The imports from all sources into Great Britain were: in 1872, 784,000 tons; 1873, 833,500 tons; 1874, 835,000 tons. The consumption in the same years was 715,000, 786,000, and 836,000 tons. The importations of foreign refined, mainly beet sugar from France, were: in 1872, 87,700 tons; 1873, 118,000 tons; 1874, 136,000 tons. The production of beet sugar holds the balance of power in the sugar markets of the world. In the ten crop years from 1864–'5 to 1874–'5 the production increased from 545,000 to 1,054,000 tons. The principal producing countries are France, about 450,000 tons, and Germany, about 280,000 tons; the remainder is produced in Austria, Russia, and Holland.—Among the treatises on cane culture and the manufacture of sugar are: Champomier, "Statement of the Sugar Crop made in Louisiana" (annual reports, New Orleans, 1845–'57); Evans, "Sugar Planter's Manual" (London, 1847; Philadelphia, 1848); Wray, "Practical Sugar Planter" (London, 1848; latest ed., 1871); Leon, "Sugar Cultivation in Louisiana, Cuba, and the British Possessions" (London, 1848); Kerr, "Practical Treatise on the Cultivation of the Sugar Cane, and the Manufacture of Sugar" (London, 1851); Burgh, "Manufacture of Sugar and the Machinery Employed" (London, 1866); Reed, "History of Sugar and Yielding Plants" (London, 1866); and Soames, "Treatise on the Manufacture of Sugar" (London, 1872). The manufacture of beet sugar is described by Dumas in his *Traité de chimie appliquée aux arts*, vol. vi.; see also Dureau, *De la fabrication du sucre de betterave* (Paris, 1858); Grant, "Beet-Root Sugar and Cultivation of Beet" (Boston, 1867); and Crooks, "Manufacture of Beet-Root Sugar" (London, 1870).

**SUGAR OF LEAD.** See LEAD, vol. x., p. 246.

**SUGAR OF MILK.** See MILK, SUGAR OF.

**SUICIDE.** See FELO DE SE.

**SUIDAS**, a Greek lexicographer, supposed to have lived shortly after the 10th century A. D. His "Lexicon" contains articles on geography, biography, and history, under proper names, which are given coördinately with the words of the Greek language, and contains many extracts from ancient Greek writers, the works of some of whom are lost. It appears to have received additions from various hands. The first edition was published by Demetrius Chalcondyles (fol., Milan, 1499); the best are those of T. Gaisford (3 vols. fol., Oxford, 1834) and Bernhardy (4 vols., Halle, 1834–'53).

**SULIOTES**, a people of mixed Albanian and Greek descent, who formerly dwelt in the southern part of the pashalik of Janina, the ancient Epirus. They derive their origin from a number of families who in the 17th century fled from the tyranny of the Turks and took possession of the ridge of the Suli mountains and the valleys on both sides of it. In the second half of the 18th century the population numbered about 10,000, half Parasuliotes (subjugated people of different origin), and dwelt in 70 villages, Kako-Suli, 1,200 ft. above the river Acheron, being the chief. Near this village they erected the castle of Suli on a semilunar mountain, which terminates in so narrow a ridge as hardly to leave a path from one fortification to another. The Suliotes belonged to the Greek church, and their language was Albanian, although they also spoke Greek; their form of government was a mixture of oligarchy and democracy. They were divided into about 30 tribes or clans. In war they usually fought as skirmishers, each clan having its captain, subject to an officer called polemarch, who was elected by vote. In the war of 1787–'92 between Russia and Turkey, the Suliotes strongly supported the former power, defeated in 1789 the troops of Ali Pasha of Janina, ravaged Acarnania to the Achelous in 1790, and afterward invaded Arta and Janina, and aided the corsair Lambro Canzani with men and money. Deserted by the Russians after the peace of 1792, they fought desperately and successfully against the troops of Ali Pasha, who sought to exterminate them, and secured a truce for a few years. But in May, 1801, Ali renewed the war and put large numbers to the sword; the women threw themselves into the river rather than be captured. Most of the survivors, about 4,000, in 1803 retired to Parga. Compelled by Ali to leave this place, they went to the Ionian islands. Many afterward enlisted in the Greek regiments raised by the English during the war, which were disbanded in 1814. When in 1820 Ali Pasha, in revolt against the Porte, was hard pressed by the Turks under Kurshid Pasha, and deserted by the Albanians, he recalled the Suliotes. The tyrant of Janina fell in 1822, but the Suliotes remained hostile to the Porte, adhering to the cause of Grecian liberty. In spite of the heroic efforts of their leader, Marco Bozzaris, the Suliotes were hemmed in in their inaccessible valley; and at last, Suli being taken, Sept. 4, 1822, they accepted the offer of an asylum from the governor of the Ionian islands. About 2,000 were carried in English ships to Cephalonia, the remainder dispersing among the mountains.

**SULLA**, or **Sylla, Lucius Cornelius (Felix)**, a Roman dictator, born in 138 B. C., died in 78.

The family was originally called Rufinus and belonged to the great Cornelia *gens*. He acquainted himself with Greek and Roman literature, and was said to have all the accomplishments and all the vices of the day. Inheriting the property of his stepmother and of a courtesan, he aspired to the honors of state. In 107 B. C. he was elected quæstor, and was sent with cavalry to Africa to aid Marius in the Jugurthine war. Marius regarded him as a profligate patrician ignorant of war, but Sulla's conduct soon won his esteem and the affection of his soldiers. He took a leading part in the battle of Cirta and in the transactions which ended in the betrayal of Jugurtha. In 104 he was legate under Marius during the threatening invasion of the Cimbri and Teutons; in 103 he was military tribune; in 102 he left Marius, who had become jealous of him, to serve under Q. Catulus, who made him chief manager of affairs; and in 101 he was engaged in the great battle which completely destroyed the Cimbri. In 93, by a liberal distribution of money among the people, he gained the prætorship. In 92 he was sent as proprætor to Cilicia to restore Ariobarzanes to his kingdom of Cappadocia, from which Mithridates had expelled him. His success attracted the attention of Arsaces, king of Parthia, who sent an embassy to Sulla to solicit an alliance with the Romans. On his return to Rome both he and Marius, representatives of the aristocratic and popular parties respectively, desired the command of the army in the impending war against Mithridates; but the breaking out of the social war checked their private feuds and united the two generals against the common foe. In this war Sulla's successes far outshone those of Marius; but his most brilliant exploits were in 89, when as legate of the consul L. Cato he destroyed Stabiæ, subjugated the Hirpini, defeated the Samnites, and captured their chief town, Bovianum. In 88 he became consul, and was appointed to the command against Mithridates. Marius conspired with the tribune P. Sulpicius Rufus and with the lately enfranchised Italians to wrest this command from Sulla, and succeeded in driving him out of the city. He hastened to the army then besieging Nola, persuaded six legions to march under him against Rome, entered the city, and drove out Marius. Early in 87 he joined his troops at Capua, embarked for Greece, and began the war against Mithridates. In 86, after a long siege, he took and plundered Athens, and from this time till his return to Rome in the spring of 83 he enjoyed almost uninterrupted success. In the mean time Marius and L. Cinna returned to Rome and were elected consuls. Sulla was declared a public enemy, and against both him and Mithridates was sent an army, which in 85, under Fimbria, gained several victories over the armies of Mithridates in Asia, while Sulla in the same year defeated his army in Greece. In 84 Sulla made peace with Mithridates, and turning his attention to Fimbria, then at Thyatira, he defeated him. Fimbria, deserted by his soldiers, committed suicide. Sulla exacted enormous sums from Asiatic cities, and then set sail with his army for Athens, from which he carried to Rome the celebrated library of Apellicon. Although both Marius and Cinna were dead, the Marian party were still strong against Sulla; but by victories, by intrigues, and by seducing their soldiers to join his own army, Sulla succeeded in shutting up the younger Marius in Præneste, and leaving a force to besiege the place, he hastened with the bulk of his army to Rome, which was threatened by the Samnites and Lucanians. Both armies arrived almost simultaneously, and before the Colline gate was fought, Nov. 1, 82, the great battle in which 50,000 men on each side are said to have fallen. The victorious Sulla massacred all his Samnite prisoners. Præneste soon surrendered; the Prænestines and Samnites were slaughtered, and the younger Marius killed himself. This ended the Marian war. The next step of Sulla, now master of Rome, was to extirpate the popular party. At the close of 82 the dictatorship, which had been in abeyance for about 130 years, was revived, and Sulla as dictator had absolute power over the lives and property of all citizens. A reign of terror followed. Sulla posted in the forum a list called a *proscriptio* of persons to be considered as outlaws, who might be killed by any one, and their confiscated property was to be sold at auction. Fresh lists constantly appeared, till Sulla was rid of his enemies, while their property helped to enrich his friends. But he did not intend to abolish the republic, and in 80 he was elected consul, still holding the dictatorship. In 80–79 he introduced his reforms in the constitution and established military colonies throughout Italy. All his reforms were by *leges*, including the laws relating to the constitution, to the religious corporations, to the administration of justice, and to the improvement of public morals. Having effected these reforms, he voluntarily resigned the dictatorship in 79, and retired to his estate at Puteoli, where he devoted himself to literary and sensual enjoyments. His excesses shortened his life; the immediate cause of his death was the rupture of a blood vessel. He had just completed the 22d book of his memoirs, which have not come down to us, but were largely used by Plutarch. The senate gave him a public funeral, which was a gorgeous pageant. His monument in the Campus Martius bore an inscription, said to have been composed by himself, to the effect that none of his friends ever did him a kindness, and none of his enemies a wrong, without being fully repaid. His constitutional reforms endured but a few years, and only paved the way for the advent of the Cæsars.

**SULLIVAN**, the name of six counties in the United States. **I.** A W. county of New Hamp-

shire, drained by small tributaries of the Connecticut river; area, about 820 sq. m.; pop. in 1870, 18,058. The valley of the Connecticut is level and contains much excellent land; the rest of the county is broken and sometimes hilly. It is traversed by several railroads. The chief productions in 1870 were 16,864 bushels of wheat, 138,071 of Indian corn, 124,819 of oats, 13,945 of barley, 286,721 of potatoes, 206,629 lbs. of wool, 576,725 of butter, 100,429 of cheese, 342,398 of maple sugar, and 54,583 tons of hay. There were 3,615 horses, 6,832 milch cows, 3,122 working oxen, 8,631 other cattle, 39,078 sheep, and 2,829 swine; 9 manufactories of woollen goods, 5 of wooden ware, 3 of paper, 5 of machinery, 2 of cotton goods, 2 of boots and shoes, 5 flour mills, 6 tanneries, 4 currying establishments, and 24 saw mills. Capital, Newport. **II.** A S. county of New York, separated from Pennsylvania by the Delaware river, and watered by several streams; area, about 880 sq. m.; pop. in 1875, 34,935. The surface is elevated and intersected N. E. and S. W. by several ridges. The valleys are generally wide and fertile. It is traversed by the Delaware and Hudson canal and several railroads. The chief productions in 1870 were 5,136 bushels of wheat, 49,025 of rye, 181,551 of Indian corn, 231,954 of oats, 130,421 of buckwheat, 236,881 of potatoes, 22,011 lbs. of wool, 1,183,642 of butter, and 65,992 tons of hay. There were 4,168 horses, 13,987 milch cows, 4,369 working oxen, 12,568 other cattle, 12,352 sheep, and 5,471 swine; 18 manufactories of carriages and wagons, 15 flour mills, 34 tanneries, 8 currying establishments, and 45 saw mills. Capital, Monticello. **III.** A N. E. county of Pennsylvania, drained by tributaries of the Susquehanna river; area, about 450 sq. m.; pop. in 1870, 6,191. The surface is generally rolling and hilly. The chief productions in 1870 were 16,360 bushels of wheat, 5,678 of rye, 42,942 of Indian corn, 76,141 of oats, 34,453 of buckwheat, 52,507 of potatoes, 21,219 lbs. of wool, 20,700 of maple sugar, 229,972 of butter, and 13,446 tons of hay. There were 1,074 horses, 2,705 milch cows, 3,990 other cattle, 6,976 sheep, and 1,982 swine; 1 flour mill, 5 tanneries, 2 currying establishments, and 6 saw mills. Capital, Laporte. **IV.** A N. E. county of Tennessee, bordering on Virginia and intersected by the Holston river; area, 300 sq. m.; pop. in 1870, 13,136, of whom 857 were colored. The surface is very hilly and well timbered, and the soil fertile. Iron ore and coal are found. The East Tennessee, Virginia, and Georgia railroad passes through it. The chief productions in 1870 were 132,647 bushels of wheat, 302,227 of Indian corn, 176,387 of oats, 16,307 lbs. of tobacco, 27,026 of wool, 171,872 of butter, 7,785 of flax, 12,360 of maple sugar, 18,120 of honey, and 20,077 gallons of sorghum molasses. There were 3,384 horses, 3,405 milch cows, 5,535 other cattle, 15,634 sheep, and 18,478 swine; 13 flour mills, and 3 saw mills. Capital, Blountsville. **V.** A S. W. county of Indiana, separated from Illinois by the Wabash river; area, 430 sq. m.; pop. in 1870, 18,453. The surface is generally level and the soil fertile. The chief productions in 1870 were 297,452 bushels of wheat, 766,801 of Indian corn, 93,736 of oats, 43,692 of potatoes, 9,805 tons of hay, 4,125 lbs. of tobacco, 67,640 of wool, 176,279 of butter, 42,250 of maple sugar, and 39,166 gallons of sorghum molasses. There were 6,912 horses, 4,892 milch cows, 7,027 other cattle, 27,246 sheep, and 32,030 swine; 4 cooperages, 8 flour mills, and 19 saw mills. The Evansville and Crawfordsville railroad passes through the capital, Sullivan. **VI.** A N. county of Missouri, drained by tributaries of Grand river; area, 648 sq. m.; pop. in 1870, 11,907, of whom 42 were colored. The surface is rolling, about two thirds being prairie and one third timbered. The soil is productive; coal is found. The chief productions in 1870 were 61,467 bushels of wheat, 15,826 of rye, 412,624 of Indian corn, 164,614 of oats, 38,754 of potatoes, 26,619 lbs. of tobacco, 70,094 of wool, 234,065 of butter, and 14,569 tons of hay. There were 6,171 horses, 665 mules and asses, 5,024 milch cows, 9,926 other cattle, 25,369 sheep, and 17,770 swine; 11 flour mills, 5 saw mills, and 3 wool-carding and cloth-dressing establishments. Capital, Milan.

**SULLIVAN, Arthur S.**, an English composer, born in London in 1844. He was instructed by his father, a music teacher, and sang for three years when a boy at the chapel royal. At the age of 14 he gained the Mendelssohn scholarship, and continued his studies at the royal academy under John Goss and Sir Sterndale Bennett. He then studied under Rietz, Hauptmann, and Moscheles, in Leipsic, and composed the incidental music to Shakespeare's "Tempest," performed for the first time at the crystal palace in 1862. He soon after composed an opera, never played, with the libretto by Chorley, entitled "The Sapphire Necklace." He has written three cantatas, "Kenilworth," "On Sea and Land," and "The Bride of Neath Valley;" a symphony performed at Liverpool in 1866; several overtures; three operettas, "Thespis," "Contrabandista," and "Box and Cox;" and two oratorios, "The Prodigal Son," produced at the Worcester festival in 1868, and "The Light of the World," produced at the Birmingham festival in 1873. He has also composed songs and piano music, including "The Songs of the Wrens," for which the words were written by Alfred Tennyson.

**SULLIVAN, Barry.** See p. 900.

**SULLIVAN. I. John**, an American general, born in Berwick, Me., Feb. 17, 1740, died in Durham, N. H., Jan. 23, 1795. He practised law in Durham. In 1774 he was a member of the first general congress, and in December of that year, with John Langdon, led a force against Fort William and Mary, near Portsmouth, and seized 100 barrels of gunpowder, 15 cannon, all the small arms, and other stores.

This was the first act of armed hostility committed in the colonies. In June, 1775, he was appointed by congress a brigadier general, and commanded on Winter hill at the siege of Boston. After its evacuation he was sent to reenforce the army in Canada, where, after the death of Gen. Thomas, he took command, June 2, 1776, and conducted the retreat from the province. He was commissioned by congress as major general, Aug. 10, acted under Putnam on Long Island, and by a combat of two hours in the woods (Aug. 27) contributed to the preservation of the American army. He was taken prisoner, but was exchanged for Gen. Prescott. After Gen. Lee's capture Sullivan took command of his division, and led the right at Trenton on Christmas night, 1776. On Aug. 22, 1777, he made a bold descent on Staten Island, the entire success of which was prevented by misconstruction of his orders, but he was justified by a court of inquiry and by a vote of congress. He commanded the right wing at the battle of Brandywine. He defeated the British left at Germantown, but mistakes on the American left, occasioned by fog, changed a victory into a repulse. In August, 1778, he commanded in Rhode Island, and prepared to attack the British lines at Newport, but was deprived of the coöperation of the French fleet under D'Estaing, and was obliged to raise the siege; but at Butt's hill, on the 29th, he repulsed the enemy, and withdrew from the island with slight loss. On Aug. 29, 1779, he defeated the Indians under Brant and tories under Sir John Johnson, at Newtown, near the present site of Elmira, N. Y. He then resigned his commission on account of ill health. In the autumn of 1780 he again took his seat as a member of congress. In 1782-'6 he was attorney general of New Hampshire, and in 1786-'9 president of the state. In the troubles of 1786 he saved the state from anarchy by his intrepidity and good management, and in 1788 secured the ratification of the federal constitution. In 1789 he was appointed federal judge of New Hampshire, which office he held till his death. His life has been written by O. W. B. Peabody, in Sparks's "American Biography," 2d series, vol. iii., and by Thomas C. Amory (1868).—His son George (1774-1838) was an eminent lawyer, and was several times a member of the legislature, of congress 1811-'13, and attorney general of the state 1805-'7 and 1816-'35. **II. James**, governor of Massachusetts, brother of the preceding, born in Berwick, Me., April 22, 1744, died in Boston, Dec. 10, 1808. He was king's attorney for York co., Me., but joined the revolutionary movement. He was a member of the provincial congress of Massachusetts (of which Maine then formed a part) in 1775, and with two others executed a difficult commission to Ticonderoga. In 1776 he was appointed a judge of the superior court, and in 1779-'80 was a member of the convention which framed the constitution of the state. In 1783 he was chosen a member of congress; and he was repeatedly elected a representative of Boston (to which place he had removed) in the legislature. In 1787 he was a member of the executive council and judge of probate for Suffolk co., from 1790 to 1807 was attorney general of the state, and was elected governor in 1807 and 1808. He was one of the commissioners for settling the boundaries between the United States and the British provinces. He published a "History of the District of Maine" (1795), and "History of Land Titles in Massachusetts" (1801). **III. William**, son of the preceding, born in Saco, Me., Nov. 30, 1774, died in Boston, Sept. 3, 1839. He graduated at Harvard college in 1792, studied law, and was long president of the association of the Suffolk bar. He was constantly a member of one or the other branch of the state legislature. He published "Familiar Letters on Public Characters and Events from 1783 to 1815" (12mo, Boston, 1834); "Historical Causes and Effects, from the Fall of the Roman Empire to the Reformation in 1517" (8vo, 1838); and "The Public Men of the Revolution," published with a biographical sketch by his son, J. T. S. Sullivan (8vo, Philadelphia, 1847). **IV. John Langdon**, an American engineer, brother of the preceding, born in Saco, Me., April 9, 1777, died in Boston, Mass., Feb. 9, 1865. He travelled in Europe, studying the construction of canals in France and England, and in 1804 was appointed agent and engineer of the Middlesex canal, which was completed in seven years. He invented the steam towboat, for which he received a patent in 1814, in preference to Robert Fulton, who applied for it at the same time, his priority of discovery being fully sustained. In 1824 he was appointed associate civil engineer of the United States board of internal improvements, which post he resigned the next year, after making a report on the practicability of a canal across the Alleghanies. He then studied medicine, in 1837 commenced practice in New Haven, afterward adopted the homœopathic system, and in 1847 removed to New York.

**SULLIVAN'S ISLAND.** See Moultrie, Fort.

**SULLIVANT, William Starling**, an American botanist, born at Franklinton, near the site of Columbus O., Jan. 15, 1803, died in Columbus, April 30, 1873. He graduated at Yale college in 1823, and settled in Columbus as a surveyor. In 1840 he published a "Catalogue of Plants, Native or Naturalized in the Vicinity of Columbus, Ohio," and in 1842 an article on three new plants discovered in that district. He made a journey in 1843 from Maryland to Georgia, and published "Musci Alleghanienses" (55 sets, of 2 vols. 4to each, 1845; new ed., printed privately, 1855). He wrote papers on bryology and hepaticology for the "Memoirs of the American Academy of Arts and Sciences" (1846-'9), and contributed the "Musci and Hepaticæ of the United States East of the Mississippi River" to the second edition of

Gray's "Manual of Botany" (1856); this was afterward published separately. A second volume of this, his most important work, has appeared since his death. *Musci Boreali-Americani*, consisting of 350 species and varieties of dried mosses, was the joint work of himself and his associate L. Lesquereux (1856). He also published "Mosses brought home by Wilkes's Exploring Expedition, 1838–'42" (with 26 fol. plates, 1859); "Mosses and Hepaticæ collected mostly in Japan" (with 18 4to plates, 1860); *Musci Cubenses* (1861); and *Icones Muscorum* (with 129 plates, 1864). The genus *Sullivantia* was founded by Torrey and Gray upon a rare plant of the saxifrage family discovered by him.

**SULLY**, a S. central county of Dakota, recently formed and not included in the census of 1870; area, about 1,300 sq. m. It is bounded W. by the Missouri and watered by its affluents. The surface is mostly undulating prairies. The Missouri bottom is very productive.

**SULLY, Maximilien de Béthune**, baron de Rosny, duke of, a French statesman, born at Rosny, near Mantes, Dec. 13, 1560, died near Chartres, Dec. 22, 1641. He belonged to a noble Protestant family, and followed King Henry of Navarre in all his wars, and became his chief adviser. When his master, on the death of Henry III., claimed the throne of France, Rosny advised him to turn Catholic in order to reconcile the majority of the nation to his cause. On a secret mission to Queen Elizabeth of England, he secured her assistance to Henry IV., and he was instrumental as an engineer in taking Dreux in 1593, Laon in 1594, La Fère in 1596, and Amiens in 1597. In 1597 he was appointed superintendent of finance, and became in fact the chief minister of Henry IV. He reformed the financial system, and cancelled the public debt, which amounted to 332,000,000 livres, remitting 20,000,000 taxes in arrears, alleviating the annual taxation, and gathering a reserve of 17,000,000, which was deposited in the Bastile. He fostered agriculture, made the grain trade free, suppressed tolls and prohibitions, built or improved highways and roads, constructed canals, and encouraged drainage and mining. He had received the title of marquis of Rosny in 1601, and was created duke of Sully in 1606. At the death of Henry IV. in 1610 the reserve in the Bastile amounted to 42,000,000. Sully remained as chief minister some time longer, but his severity and rigid principles becoming obnoxious to Maria de' Medici and her advisers, he left the court in 1611, and resigned most of his offices and dignities. Cardinal Richelieu in 1634 made him marshal of France. During his retirement he composed his personal memoirs, *Mémoires des sages et royales économies d'État de Henry le Grand* (4 vols. fol., 1634–'62, several times reprinted; English translation by Mrs. Lennox, 3 vols. 4to, London, 1756; new ed., 5 vols. 8vo, 1854–'6).—See *Éloge historique de Sully*, by Perrens (Paris, 1871).

**SULLY, Thomas**, an American painter, born at Horncastle, Lincolnshire, England, in June, 1783, died in Philadelphia, Nov. 5, 1872. He was brought to the United States by his parents, who were players, in 1792. In 1803 he settled as a portrait painter in Richmond, Va., removed a few years later to New York, and in 1809 settled in Philadelphia. Among his large works are full-length portraits of George Frederick Cooke as Richard the Third, Dr. Benjamin Rush, Commodore Decatur, Thomas Jefferson, Lafayette, and Queen Victoria, painted during a visit to England. His well known picture of "Washington crossing the Delaware" is now in the Boston museum.

**SULPHATES**, salts formed by the union of sulphuric acid with bases. The union, strictly speaking, is only partial, as a portion, and in normal salts all, of the hydrogen of the sulphuric acid is displaced by the basyle. (See SALTS.) Thus, $H_2SO_4 + 2K = 2H + K_2SO_4$, normal sulphate of potassium; or $H_2SO_4 + K = H + KHSO_4$, acid sulphate of potassium. The sulphates are extensively employed in the arts, in medicine, in agriculture, and in the chemical laboratory. 1. *Sulphates of Alumina.* The normal sulphate, $Al_2 3SO_3 + 18H_2O$, is found native in many localities, as on the volcanic island of Milo in the Grecian archipelago, in the craters of volcanoes in the Andes, and at Adelaide in Australia. It is known in mineralogy as alunogen, hair salt, feather alum, and halotrichite. Its hardness is 1·5 to 2; sp. gr. 1·6 to 1·8; lustre vitreous; color white, or tinged with yellow or red. It is manufactured in large quantities, is known in commerce as concentrated alum, and is used in dyeing instead of common alum. Clay as free as possible from iron is heated to redness, and then ground and mixed with half its weight of sulphuric acid of sp. gr. 1·45, in a reverberatory furnace, till the acid begins to volatilize. After exposure to the air for several days, water is added and the solution freed from what iron it may contain by precipitation with ferrocyanide of potassium. The solution is then evaporated to a sirup, which solidifies on cooling. It is soluble in two parts of water, insoluble in alcohol. There is a series of double aluminic sulphates, forming true alums, which are treated under the head of ALUM. Not all alums contain aluminum, but they are so named because they are formed on the type of the alum salts. 2. *Sulphates of Barium.* Some of the sulphates of barium are double salts. The most important is the neutral sulphate, $BaSO_4$, or heavy spar, which is found native in large quantities, and when ground into powder is used to adulterate white lead as a pigment. An amorphous sulphate is made on a large scale for the same purpose, and called permanent white. There is an acid salt, $BaH_2 2SO_4$, and a basic soda sulphate, $BaN_2 2SO_4$. 3. *Sulphates of Calcium and Chromium.* An anhydrous neutral sulphate of calcium, $CaSO_4$, occurs native as the mineral an-

hydrite. It may be formed artificially in crystals by fusing sulphate of potash with an excess of chloride of calcium. Gypsum is native hydrated sulphate of calcium, $CaSO_4 2H_2O$. (See GYPSUM.) The sulphates of chromium, both the pure chromium and also the double salts, are an important class of compounds, and include the chrome alums, as ammonio-chrome alum, potassio-chrome alum, and sodio-chrome alum. 4. *Sulphates of Copper.* The normal sulphate, $CuSO_4 + 5H_2O$, is the blue vitriol of commerce, extensively used in the arts. (See COPPER, vol. v., pp. 318–'19.) There are several basic sulphates of copper, and double sulphates of copper and ammonia of various shades of blue, some of which form solutions of exceeding beauty. By mixing solutions of ammonio-cupric sulphates or of potassio-cupric sulphates with corresponding double sulphates of cobalt, iron, magnesium, manganese, nickel, or zinc, an interesting series of complex salts is obtained, all of which crystallize in monoclinic prisms and tables, isomorphous with the magnesium double salts; and furthermore, by mixing the solutions of three or four of these double salts, others still more complex may be formed, isomorphous with the preceding. Copper also forms with magnesium, sodium, and zinc beautiful double sulphates. In the preparation of cupric sulphate from materials which contain iron compounds, several so-called ferroso-cupric sulphates are formed, having different proportions of base, but which are not true double salts. The Salzburg vitriol, prepared at Buxweiler in Alsace, contains 3 molecules of iron to 1 of copper; Admont vitriol, 5 to 1; Baireuth vitriol, 7 to 1. 5. *Sulphates of Iron.* Sulphuric acid forms with iron an extensive series of salts, some of which have a constitution analogous to the peroxide, and are called ferric salts; others, analogous to the protoxide, are called ferrous salts. Among the former are several interesting double salts, including ammonio-ferric sulphate, or ammonia-iron alum, and potassio-ferric sulphate, or potash-iron alum. Ferrous sulphate, green vitriol, or copperas, $FeSO_4 + 7H_2O$ (or $FeOSO_3 + 7HO$, old formula), is the most important commercial salt of iron. It occurs native, sometimes in crystals, but more often in amorphous masses, in iron mines in various parts of the world, being formed by the oxidation of iron pyrites; but most of the copperas consumed in the arts is prepared simultaneously with alum from schists containing iron pyrites. Ferrous sulphate crystallizes in monoclinic prisms or tables, which when moist readily absorb oxygen and pass into ferric sulphate; but if crushed and deprived of moisture by strong pressure between folds of cotton cloth or filter paper, it may be kept in bottles for a long time without change. (See COPPERAS.) 6. *Other Metallic Sulphates.* The normal sulphate of magnesium, $MgSO_4 + 7H_2O$, is described under the title EPSOM SALT. There is an acid sulphate and several double salts. The sulphates of potassium are described with that metal. Glauber's salt is the normal and principal sulphate of sodium. (See GLAUBER'S SALT.) The other metallic sulphates of sufficient importance are treated under the heads of the respective metals. 7. *Alcoholic Sulphates.* Sulphuric acid combines with various alcohol radicals to form a series of sulphuric ethers, the most important among which are acid sulphate of ethyle, or sulphovinic acid, $(C_2H_5)HSO_4$, and neutral sulphate of ethyle, or true sulphuric ether, $(C_2H_5)_2SO_4$. (This latter ether must be distinguished from what is ordinarily called sulphuric ether, which is the oxide and not the sulphate of the radical ethyle, $C_2H_5$.) Sulphovinic acid is formed by the action of strong sulphuric acid upon alcohol, ether, or ethylene, and was first noticed by Dabil in 1800 in the residues of the preparation of common ether. The molecule of hydrogen which it contains may be replaced by a metal forming a salt which is called a sulphovinate, or ethyle sulphate. Neutral sulphate of ethyle, or true sulphuric ether, is formed by passing sulphuric anhydride into a flask containing common sulphuric ether surrounded by a freezing mixture. It is a yellowish oily liquid of sp. gr. 1·12, having a sharp taste and the odor of oil of peppermint. As it is decomposed when heated in the air, it must be distilled in an atmosphere of carbonic anhydride. Sulphuric acid forms with methyle an acid sulphate of methyle, or sulpho-methylic acid, $CH_3HSO_4$, and a neutral sulphate of methyle or methylsulphuric ether, $(CH_3)_3SO_4$. The molecule of hydrogen in sulpho-methylic acid may be replaced by a metal, forming a salt called a methyl-sulphate.

**SULPHIDES,** or **Sulphurets,** compounds in which sulphur forms the electro-negative element. Sulphur unites with all the metals, with most of the non-metallic elements, and with many organic radicals. The sulphides have generally a constitution corresponding to the oxides, and like them may be divided into acid and basic sulphides, which are capable of uniting and forming sulphur salts. Thus, we have stannate of potassium, $K_2SnO_3$, and also sulphostannate of potassium, $K_2SnS_3$. The sulphides are decomposed more or less perfectly by hydrochloric acid, and behave like the corresponding oxides, yielding one molecule of sulphydric acid for every molecule of sulphur in the sulphide. Thus, $FeS + 2HCl = H_2S + FeCl_2$; and $SbS_3 + 6HCl = 3H_2S + 2SbCl_3$. Of the sulphides of the non-metallic elements, those of carbon and chlorine are the most important. Bisulphide of carbon, carbon disulphide, or sulpho-carbonic acid, $CS_2$, is the only sulphide of carbon which is positively known. It is prepared on a large scale as a solvent for various manufacturing purposes. A large earthen retort has a tube which passes through the mouth down to near the bottom. The retort is filled with charcoal and heated to redness in a furnace, and bits of sulphur are dropped from

time to time down the tube, which after each introduction is stopped with a cork. The neck of the retort is connected with a condensing tube, which is kept cold by a stream of water, and dips into a vessel of cold water. The sulphide which collects at the bottom of this vessel contains an excess of sulphur, from which it is freed by redistillation. By another process sulphur vapor is driven over red-hot coke. Sulphide of carbon is a colorless, mobile, highly refracting liquid, its index of refraction being 1·678. (See LIGHT, vol. x., p. 439.) It has a peculiar, fetid, disagreeable, alliaceous odor, and when breathed produces great depression, followed by coma. The density of the liquid is 1·274, water=1; of the vapor, 2·67, air=1; boiling point, 118·4°. It freely dissolves sulphur, depositing it on evaporation in beautiful octahedral crystals. It also dissolves phosphorus, iodine, camphor, and caoutchouc, and mixes easily with oils. It is extensively used in the vulcanization of caoutchouc and the manufacture of gutta percha, for extracting bitumen from mineral substances, and of oil from seeds. Sulphide of chlorine, $S_2Cl_2$, is formed by passing dry chlorine over melted sulphur contained in a glass retort. A deep orange-yellow, mobile fluid distils over, having a peculiar disagreeable odor, boiling at 282° F.; sp. gr. 1·687. It dissolves sulphur in large quantities. Dissolved in crude benzole with excess of sulphur, it is also used in Europe for vulcanizing caoutchouc. The principal sulphides of organic radicals are of the alcoholic series, and form a class of ethers, as hydrosulphuric ether, or monosulphide of ethyle, $(C_2H_5)_2S$, and the disulphide, $(C_2H_5)_2S_2$. Sulphydrate of ethyle, or *mercaptan*, $C_2H_5SH$, is interesting as being the sulphur analogue of common alcohol, or hydrated oxide of ethyle, $C_2H_5OH$. (See ALCOHOL, and ETHYLE.) Mercaptan (*mercurium captans*, which signifies having a strong tendency to seize upon or combine with mercury) was discovered by Leise in 1833, and has since been examined by Liebig and others. It is a colorless mobile liquid, of an exceedingly offensive and permanent garlic odor; sp. gr. 0·842; boiling point about 144° F. When it is mixed with mercuric oxide, violent reaction ensues, with formation of water, and a white substance, soluble in alcohol, which by the action of sulphydric acid yields sulphide of mercury with reproduction of mercaptan. A drop on the end of a glass rod waved through the air will evaporate so rapidly as to freeze a portion remaining. It forms an interesting class of compounds with other elements, for which the reader is referred to larger works on chemistry. The sulphides of methyle, $(CH_3)_2S$ and $(CH_3)_2S_2$, and also methyle sulphydrate, or methyle mercaptan, $CH_3SH$, and other organic sulphides and sulphydrates, possess much chemical interest.

**SULPHITES,** salts formed by the union of sulphurous acid with bases, or more strictly speaking by the action of sulphurous acid on bases; the two atoms of hydrogen in the molecule of the acid being partially or wholly replaced by a metallic basyle or a radical, forming normal and acid salts. (See SALTS.) Thus, normal sulphite of potassium, $K_2SO_3$, may be formed by wholly replacing the hydrogen in the acid, $H_2SO_3$; or the acid sulphite, $KHSO_3$, may be formed by employing half the quantity of acid. The sulphites of the metals are usually formed by passing sulphurous anhydride, $SO_2$, through aqueous solutions or mixtures of hydrates or carbonates, the anhydride being first converted into the acid by combining with the elements of water, whereupon double decomposition immediately takes place, with an exchange between the metallic basyle and the hydrogen constituent of the acid. Sulphurous acid combines with nearly all the metals, the most important sulphites being those of calcium and sodium. Sulphite of calcium may be precipitated in an anhydrous state by passing sulphurous anhydride through water having hydrate of lime in suspension, or through a solution of chloride of calcium. It is manufactured on a large scale and used in bleaching, and for protecting organic substances from decay. The sulphites of sodium comprise a normal salt, $Na_2SO_3$, and an acid salt, $NaHSO_3$. The normal salt is prepared by saturating a solution of carbonate of soda with sulphurous acid and adding to it as much carbonate of soda as it originally contained while warm. On cooling, the salt separates in monoclinic crystals, having seven molecules of water of crystallization ($Na_2SO_3+7H_2O$). Another hydrate was formed by Muspratt, containing ten molecules of water. The acid sulphite is prepared by supersaturating the solution of sodic carbonate with sulphurous acid. Both of these salts have been used to remove the traces of chlorine in paper pulp, under the name of antichlor, but they have been partially superseded by hyposulphite of sodium, or this salt is used in connection with them. (See PAPER.)—The two atoms of hydrogen in the molecule of sulphurous acid may be partly or wholly replaced by monatomic alcohol radicals, forming acid and neutral sulphurous ethers, the acid ethers being sometimes called sulpho-acids. Ethylsulphurous acid, $(C_2H_5)HSO_3$, is formed by the action of nitric acid on sulphydrate of ethyle or mercaptan, $(C_2H_5)HS$. Neutral sulphurous ether, $(C_2H_5)_2SO_3$, may be formed, among other methods, by the action of absolute alcohol on disulphide of chlorine. The alcoholic sulphites and other sulpho-ethers and compounds have been carefully studied by Muspratt, Gerhardt, Rammelsberg, Kolbe, and others. They form an extensive and interesting series.

**SULPHUR,** an elementary substance belonging to the class of metalloids. It has been known from the earliest times as the sublimed product of volcanoes, and as a natural mineral deposit in clay and marl strata in tertiary formations, and is also associated with gypsum, being one of the sources of this mineral. (See GYPSUM.)

It occurs in some schistose rocks, and in coal and lignite deposits, and is deposited from the sulphuretted waters of certain mineral springs. It is found in Sicily in beds of blue clay lying in a matrix of rock salt, gypsum, and celestine. (See STRONTIUM.) It also exists in primitive rocks, as granite and mica, and abounds in the lava fissures of volcanic craters, as in the *solfatara* near Naples and at Popocatepetl, Mexico. It is a constituent of many minerals, such as iron and copper pyrites, galena or sulphuret of lead, cinnabar or sulphuret of mercury, gray antimony, and realgar or sulphuret of arsenic; also of ternary salts of metals, such as the sulphates of copper and iron, and of strontia, barium, and calcium (celestine, heavy spar, and gypsum); and of more soluble compounds which are constituents of mineral waters, as the sulphates of magnesium and sodium (Epsom and Glauber's salts). It is a constituent of the proteine compounds of animals and vegetables, in the taurine of bile and the cystine of urine, and certain volatile oils, as oil of onions and oil of mustard.—Sulphur is obtained from the natural deposits of free sulphur by melting or by distillation. Rich deposits are simply melted in large cast-iron or earthen caldrons, the gangue and small stones being removed with perforated ladles. Sometimes rude furnaces somewhat like lime kilns are employed for the coarser deposits, in which a portion of the sulphur is burned, while the great mass is drawn off at the bottom. A better method than the latter is that of distillation, as the product is much purer. This is done in large earthen pots or retorts placed in a long furnace. Rude receivers of earthenware or wood are placed outside of the furnace in which the sublimate is condensed. The product obtained by melting is known as rough sulphur, and contains about 3 per cent. of foreign matter, from which it is separated by distillation, in stills having large chambers for condensers, in which it is deposited in the form known as flowers of sulphur; or it may be condensed in the liquid form in smaller and hotter receivers, and cast into cylinders called roll sulphur. Sulphur may also be obtained from iron pyrites by heating it in close vessels, in which case the dioxide parts with one molecule of sulphur and becomes protoxide. It is one of the products of the heating of copper pyrites preliminary to copper smelting. Sulphur is also a by-product of gas manufacture when salts of iron are used to decompose sulphuretted hydrogen. (See GAS, vol. vii., p. 637.) The iron salt, which before using is mixed with lime and exposed to the air to convert it into peroxide, in the gas-purifying process becomes a hydrated sulphide. This is again reconverted into peroxide by exposure to the air, with evolution of sulphur.—*Properties.* Native sulphur occurs either in amorphous masses, or in transparent yellow crystals derived from the octahedron with a rhombic base. Sublimed sulphur of commerce, known as flowers of sulphur, is a yellow gritty powder having a slight peculiar odor, but from its insolubility is nearly tasteless. It is a non-conductor of electricity, and becomes negatively excited on being rubbed by most substances. It has a strong affinity for oxygen, taking fire when heated in the air to 455°, burning with a blue flame and emitting suffocating fumes of sulphurous anhydride. It is therefore classed among highly inflammable substances. It melts at 239°, forming an amber-yellow liquid which is lighter than solid sulphur. It boils at about 836°, forming a deep yellow vapor of sp. gr. 6·617, one volume of which contains three atoms of sulphur. When heated to about 1832° the vapor is only one third as dense as at 900°, and then has the same atomic volume as oxygen. Sulphur has also a very strong affinity for chlorine, bromine, and iodine, forming respectively chlorides, bromides, and iodides of sulphur. It combines readily with most of the metals, forming sulphides or sulphurets, which generally have a constitution corresponding to the oxides of the same metals. Sulphur, like phosphorus, is remarkable for the number of modifications or allotropic conditions which it may assume under different circumstances. (See ALLOTROPISM, and PHOSPHORUS.) These different modifications are divided into two distinct varieties, those in the first variety being soluble and those in the second insoluble in bisulphide of carbon. Berthelot has named the first or soluble variety electro-positive sulphur, because it is separated at the positive electrode of a galvanic battery during the electrolysis of a solution of hydrosulphuric acid, and also because it is in this form that it is separated from sulphides of electro-positive metals. The second variety he named electro-negative sulphur, because it appears at the negative pole of the battery during the decomposition of sulphurous acid, and separates from sulphur compounds with electro-negative elements, as chlorine, bromine, iodine, and oxygen. Soluble sulphur, or that which is soluble in bisulphide of carbon, presents three forms, two crystalline and one amorphous. In the first the crystals are octahedrons with a rhombic base, and all the modifications of both varieties have a tendency finally to assume this form. It is formed when sulphur separates from its solutions at common temperatures. The second crystalline form is that of brownish yellow needles belonging to the oblique prismatic system. It is obtained by melting a mass of sulphur, allowing it to solidify on the surface, piercing the crust, and allowing the fluid portion to run out. On breaking away a part of the crust the long, needle-like crystals will be exposed to view. These two forms are not only very unlike as to their crystallography, but differ widely in their specific gravities and in their melting points, the octahedral crystals having a density of 2·05 and melting at 239° F., while the needles have a density of only 1·98, that of ordinary roll sul-

phur, and melt at 248°. After a time the prismatic crystals will be found to consist of aggregations of minute octahedral crystals. When a saturated solution of sulphur in hot turpentine cools, the first crystals formed will be prismatic, while those which are deposited when the solution is comparatively cool will be octahedrons. Roll sulphur or brimstone is at first prismatic, but after keeping becomes octahedral, and the change of form is attended with the evolution of heat. The amorphous variety of soluble sulphur is precipitated as a greenish white emulsion on adding acids to dilute solutions of alkaline polysulphides. This amorphous sulphur changes after a time into a mass of octahedral crystals. Ordinary sublimed sulphur (flowers of sulphur) belongs to this variety, but always contains small quantities of one of the insoluble modifications. The principal modifications of the insoluble variety of sulphur are: 1, an amorphous modification, obtained as a soft pasty mass, or magma, by decomposing bisulphide of chlorine with water, or by adding dilute hydrochloric acid to a solution of a hyposulphite; 2, a plastic form, obtained by pouring viscid sulphur raised to nearly 500° into cold water. The effect of heat upon sulphur is remarkable. It begins to melt at about 239°, and between 248° and 284° it is yellow, transparent, and limpid. As the temperature rises to 356° it becomes brown, and at last nearly black and opaque and quite viscid. At this point the temperature becomes stationary for a time, although the supply of heat is kept up, in consequence of a molecular change which is going on. Soon the temperature again rises, and when it has reached about 500° the mass becomes more liquid, but retains considerable viscosity. If it is now suddenly cooled by pouring it in a small stream into cold water, a brown tenacious mass is produced, which may be drawn out into elastic threads having a specific gravity of only 1·957. In a few hours it becomes yellow and opaque, and passes into the octahedral form. If the ductile sulphur is heated to 212°, the change is sudden, with a further rise of heat, from condensation, to 230°.—*Compounds.* Sulphur forms with oxygen an interesting series of compounds: two anhydrous oxides, or anhydrides, sulphurous anhydride, $SO_2$, and sulphuric anhydride, $SO_3$; two acids, sulphurous and sulphuric, formed by the union of these anhydrides respectively with water, and a further series of acids which have no corresponding anhydrides. The constitution of all these bodies is remarkably illustrative of the law of multiple proportions. The formulas of the acids are as follows:

| | |
|---|---|
| Hyposulphurous acid | $H_2SO_2$ |
| Sulphurous acid | $= SO_2+H_2O = H_2SO_3$ |
| Sulphuric acid | $= SO_3+H_2O = H_2SO_4$ |
| Thiosulphuric (sometimes called hyposulphuric) acid | $H_2S_2O_3$ |
| Dithionic acid | $H_2S_2O_6$ |
| Trithionic acid | $H_2S_3O_6$ |
| Tetrathionio acid | $H_2S_4O_6$ |
| Pentathionic acid | $H_2S_5O_6$ |

Thiosulphuric acid (Gr. θεῖον, sulphur) is so called because it has the constitution of sulphuric acid with a molecule of oxygen replaced by one of sulphur. The last four acids in the table are called polythionic acids, because they contain varying proportions of sulphur united with constant proportions of the other elements. Sulphurous anhydride, $SO_2$, formerly called sulphurous acid, is the only product when sulphur is burned in dry air or oxygen gas. When the combustion takes place in pure oxygen, it is found that on returning to its former temperature the gaseous product is doubled in weight, but that its volume is unchanged. It is in fact formed by the condensation of one volume of oxygen and half a volume of sulphur vapor into one volume. When required pure, sulphurous acid is usually obtained by the partial reduction of sulphuric acid. This is conveniently effected by boiling strong oil of vitriol with copper turnings or mercury. The reaction is shown in the following equation: $Cu + 2H_2SO_4 = CuSo_4 + 2H_2O + SO_2$. It may also be obtained by passing the vapor of sulphuric acid over red-hot platinum foil or sponge, the product being sulphurous anhydride and oxygen. (See Oxygen, vol. xii., p. 769.) Sulphurous anhydride is a colorless gas, having a density of 2·21. When subjected to a pressure of three atmospheres at common temperatures, or if cooled to 0° F. at the ordinary pressure, it is condensed to a colorless, transparent liquid, which solidifies to a crystalline mass at −105°. The liquid anhydride may be obtained in large quantities by passing the gas from the generator first through a small quantity of water to wash it, then through a tube surrounded by ice to remove moisture, then through a tube containing pieces of calcium chloride to dry it completely, and finally through a worm, or into a receiver immersed in a mixture of salt and ice. It may be preserved in sealed glass tubes, or corked and wired soda bottles. Sulphurous anhydride dissolves in water, forming a solution of sulphurous acid, $H_2SO_3$, which again decomposes by the application of gentle heat into the anhydride and water. Water at 60° absorbs about 45 times its volume of the gas, the resulting liquid having a density of 1·04. By exposure to the air the solution slowly passes into sulphuric acid. By cooling a saturated aqueous solution to 32°, Döpping obtained the pure acid, $H_2SO_3$, in cubical crystals. A crystalline hydrate, $SO_2SH_2O$, according to Pierre, may also be obtained at a low temperature, which melts at 39°, suffering decomposition. Sulphurous acid is a powerful reducing agent, instantly discoloring acid solutions of manganates and chromates, reducing the latter to green oxides of chromium. It reduces the salts of gold, precipitating the metal in the metallic state, and is capable of taking the second molecule of oxygen from almost any metallic binoxide. Brewers often employ a solution of sulphurous acid to wash out their beer

barrels, and in the rural districts sulphur is often burned in old cider barrels to purify them. Sulphurous acid is extensively used in bleaching straw, woollen, and silken goods, and also isinglass and other articles which would be injured by chlorine. (See BLEACHING.) It is a powerful antiseptic, and is now employed to preserve meats. (See PRESERVATION OF FOOD, vol. xiii., p. 824.) For its most important use, see SULPHURIC ACID. Sulphurous acid is dibasic, forming normal, neutral, and double salts. (See SULPHITES.) The binary compounds of sulphur with the metals, or the sulphides, are, when important, mentioned in the articles on the respective metals, or under SULPHIDES. One of the principal uses of sulphur is in making gunpowder. (See GUNPOWDER.)—*Medical Properties and Uses.* Sulphur is termed in therapeutics a laxative, diaphoretic, and alterative. It is supposed to be carried into the circulation by the fatty matters in the alimentary canal. That it is discharged by the skin is shown by the fact that silver worn about those who are taking it becomes blackened with a coating of sulphide. It is used in cutaneous and other diseases, both internally and externally, sometimes artificially prepared, and sometimes as it exists in natural springs. (See MINERAL SPRINGS.) It has been successfully employed in diphtheritic croup, given suspended in water, and in sciatica and chronic articular rheumatism, applied externally upon dry flannel and bandaged to the limb for several days. The officinal preparations embrace confections, plasters, and ointments, and precipitated sulphur or *lac sulphuris.* This latter preparation is made by boiling sulphur with milk of lime, which forms bisulphide of calcium and hyposulphite of lime, from the solutions of both of which the sulphur is precipitated by the action of hydrochloric acid. It has the general properties of ordinary sublimed sulphur, but is in a state of finer division.

**SULPHURETTED HYDROGEN.** See HYDROSULPHURIC ACID.

**SULPHURIC ACID,** the hydrate of sulphuric anhydride, or teroxide of sulphur, $SO_3 + H_2O = H_2SO_4$. It may also be regarded as a salt of hydrogen, this element holding the place of a basyle to the radical sulphion, $SO_4$. (See SALTS, vol. xiv., pp. 582, 583.) The discovery of sulphuric acid is ascribed to Basil Valentine, a monk of Erfurt in Saxony, about 1440. He obtained it by distilling green vitriol or the sulphate of iron, and as the liquid product had an oily appearance when poured out, it was called oil of vitriol. He also obtained it by burning sulphur under a bell glass containing moisture, calling the product *oleum sulphuris per campanum*, or oil of sulphur by the bell. This was the germ of the present process of manufacture, which consists in producing sulphurous acid and carrying it to a higher state of oxidation by nitrous and hyponitrous acids. The old process of distillation from green vitriol is still employed in some parts of Germany, particularly in the neighborhood of Nordhausen in Prussian Saxony, and near Prague in Bohemia. Sulphate of iron, chiefly produced by the oxidation of iron pyrites, first has its water of crystallization expelled, when it is subjected to a high

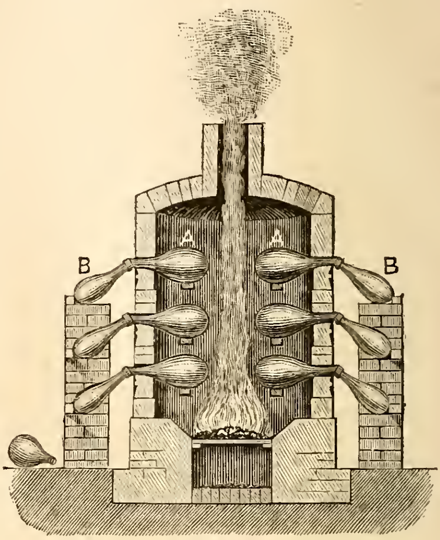


FIG. 1.—Distillation of Nordhausen Acid.

red heat in earthen retorts placed in galleries in a furnace, as shown in fig. 1. As soon as the acid begins to distil over, the necks of the retorts are passed into receivers. The product is a brown oily liquid having a density of about 1·9, and fumes in the air, for which reason it is also called fuming sulphuric acid. Its composition may be expressed by the formula $H_2SO_4,SO_3$. When gently heated it breaks up into sulphuric anhydride, $SO_3$, and sulphuric acid, $H_2SO_4$. If fuming Nordhausen acid is distilled into a receiver cooled by ice, white fumes will solidify on its sides into white silky needles. This product was formerly called anhydrous sulphuric acid. It does not however possess acid properties like the residue in the retort, but requires to be united with water to enable it to combine with bases. It is tough and ductile, and can be moulded in the fingers for a short time if they are dry. It has a specific gravity of 1·946 at 55·4°, fumes in the air, and when thrown into water hisses like red-hot iron, and forms sulphuric acid. It melts at 65° and boils at about 95°, forming a colorless vapor, which is decomposed in highly heated porcelain tubes into two volumes of sulphurous anhydride and oxygen. The common way of preparing sulphuric acid at present, known as the English process, is to oxidize sulphurous acid. It is said to have been introduced by Dr. Roebuck about the middle of the 18th century, but the invention is also

claimed for a calico printer at Rouen, with improvements by Chaptal, such claimants giving credit to Dr. Roebuck only for the invention of the leaden chambers in which the process was carried on. A large and long chamber, divided into sections by partitions which alternately leave open spaces at the top and bottom, has at one end a small furnace in which the flame of sulphur heats a crucible containing a mixture of nitre and oil of vitriol. The chamber is lined with sheet lead, and its floor is covered with a thin stratum of water. Jets of steam are also introduced. The sulphur in burning produces sulphurous anhydride, $SO_2$, which in the presence of moisture becomes sulphurous acid ($SO_2+H_2O=H_2SO_3$), and this again, by the action of $NO_5$, becomes sulphuric acid, $H_2SO_4$, the nitric acid being at the same time reduced to a lower oxide. According to the researches of Weber and Winkler, the following is the rationale of the process: The oxidation of the sulphurous acid to sulphuric acid takes place in the leaden chambers under the influence of the vapor of water, at the expense of the oxygen of the nitric or nitrous acid, which is converted into deutoxide of nitrogen. It is necessary however that the nitrous acid be first absorbed in plenty of water, which takes up the free nitrous acid and decomposes the deutoxide of nitrogen, a process greatly promoted by the presence in the chamber of sulphurous acid purposely introduced. The water, usually in the form of steam (practical experience proving that a certain elevation of temperature is required), acts in this process as in others wherein sulphurous acid effects reduction. By the presence of atmospheric air in the chamber the deutoxide of nitrogen is oxidized into hyponitric or nitrous acid, and this acid again is decomposed by sulphurous acid. A peculiar crystalline substance sometimes forms, having the formula $H_2SO_4+N_2O_3,SO_3$, and formerly thought to play an important part in the transformation; but according to R. Weber this substance only appears when the process is not well managed, and is chiefly due to want of water. The process of forming sulphuric acid may be illustrated on a small scale by means of the apparatus shown in fig. 2. A flask, *b*, furnishes sulphurous anhydride, and the bottle *e* deutoxide of nitrogen, to the large glass balloon *r*, and the flask *w* supplies steam when it is required. Air is occasionally blown into the balloon through the bent tube *t*, the effete products passing out at *o*. If but little vapor of water is present, the white crystalline solid above mentioned makes its appearance upon the sides of the globe; but when sufficient water is present the substance is not deposited, neither is it supposed to be formed as a necessary stage of the process. Gay-Lussac invented what is called a condenser as an attachment to the large leaden chambers, for the purpose of economizing the consumption of nitre, which formerly amounted to from one eighth to one twelfth of the weight of sulphur. The condenser consists of a leaden tower filled with fragments of coke, through which sulphuric acid of 66° Baumé is constantly trickling. Through this condenser the spent gases are passed, and the oxides of nitrogen which they may contain are absorbed. The sulphuric acid which collects at the bottom of the chambers is too dilute for most purposes; it is not found advantageous to allow it to attain a specific gravity of quite 1·6, because at that strength it absorbs too much of the nitrous fumes. It may be used at this strength for the manufacture of salt cake (see SODA), but for other uses it must be further concentrated. This is generally effected by two different stages, the first in leaden pans, the second in platinum or glass retorts. Some makers concentrate to 60° Baumé (sp. gr. 1·71) in leaden pans; others use them only till the acid is raised to 55° Baumé (sp. gr. 1·59). The leaden pans are rectangular, long and wide, supported by iron plates to protect the lead from immediate contact with the flame which is used for evaporation. The pans are generally arranged in steps, the acid being conveyed from the upper to the lower ones by syphons, the density of the acid increasing from one pan to the next lower. When it has attained a density of from 1·65 to 1·72 in the leaden pans, it is known as brown oil of vitriol, and may be used by bleachers, calico printers, dyers, &c.; but to raise it to the strength of commercial oil of vitriol, it is further concentrated in the glass or platinum retorts above mentioned. Glass retorts holding 20 gallons or more are often used, set in an iron pot, the bottom of which is covered with dry sand. The concentration requires from 12 to 16 hours; the vapors which distil over toward the last, carrying some acid with them, are passed into condensers and returned to the lead pans. Platinum retorts are more costly, but are thought by many to be more economical in the end on account of their not being liable to break. Fig. 3 shows a section of a platinum retort. The syphon *x* is worked without a stopcock by the vessel *c*, in the following ingenious manner. When the vessel is lowered

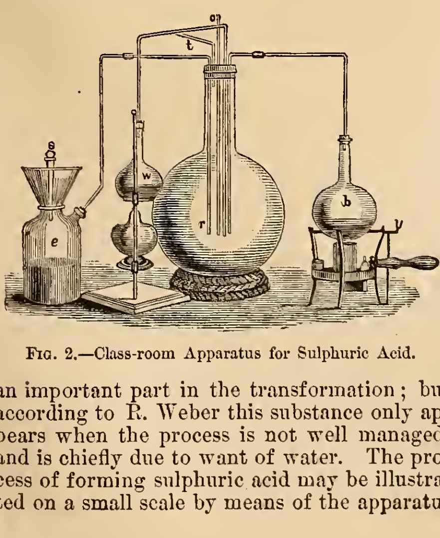

FIG. 2.—Class-room Apparatus for Sulphuric Acid.

with its spout to the gutter *d*, the outer limb of the syphon, which is constantly full, becomes lengthened below *n* (the end of one of the leaden pans), and the acid flows out, fills the movable vessel, and runs out of the spout and through the gutter *d* into the retort B. The

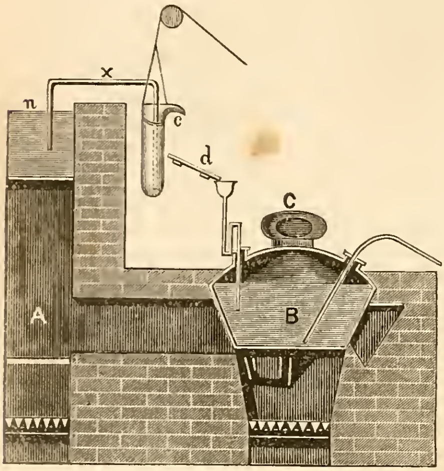

FIG. 3.—Platinum Retort.

head C communicates by means of tubing, not shown in the engraving, with a worm, where the watery vapor and the very weak acid mechanically carried over with it are condensed. The fire under the retort communicates with the flue A, which passes under the leaden pans. The concentrated acid left in the retorts contains a slight excess of water beyond that required for the formula $H_2O,SO^3$ or $H_2SO_4$. This formula gives 18·36 per cent. of the elements of water, while Marignac obtained 19·62 per cent. from the concentrated acid. According to Playfair, if the concentration is conducted at a temperature not exceeding 500° F., the true compound, of sp. gr. 1·844, is obtained; but if heated to ebullition, there is partial decomposition.—*Properties.* The oil of vitriol of commerce is an oily-looking, colorless, and odorless liquid, of sp. gr. 1·842. It chars nearly all organic substances, in consequence of abstracting from them the elements of water, leaving a carbonaceous residue. It mixes with water in all proportions, with condensation of volume of the mixture, and consequent evolution of heat. Its attraction for moisture is so great, that if exposed to the air for a few days in a shallow vessel it frequently doubles its weight; and advantage is taken of this in the laboratory for drying various substances. The boiling point of sulphuric acid is 620·6° F., and it freezes at about −29°, although when frozen it does not melt below 32°. Marignac finds that the true sulphuric acid when heated parts with a small quantity of vapor of the anhydride, and the remaining liquid boils at 640·4°. Sulphuric acid forms two definite hydrates, the monohydrate, $H_2SO_4,H_2O$, and the dihydrate, $H_2SO_4,2H_2O$. The first, of sp. gr. 1·78, crystallizes at 47° in splendid rhombic prisms, of sp. gr. 1·951. From this property it is often called glacial sulphuric acid. It boils at about 400°. The dihydrate may be formed by concentrating a dilute acid *in vacuo* at 212° till it ceases to lose weight. Its sp. gr. is 1·62; boiling point, 370°.—*Uses.* Sulphuric acid is the starting point of nearly all the great chemical manufactures. It is used to procure nitric acid from the nitrates of potassium and sodium, and hydrochloric acid from common salt, at the same time furnishing salt cake, from which the carbonates of soda are obtained. It is therefore used in the preparation of various bleaching compounds. Phosphate of lime in artificial manures is reduced to biphosphate by the action of sulphuric acid. In medicine, diluted with water or spirits of wine and known as *acidum sulphuricum dilutum* and *acidum sulphuricum aromaticum*, it is used as a tonic, refrigerant, and astringent. It is given in typhoid fevers, in convalescence from various fevers, and as an aid to digestion.

**SULPHURIC ETHER.** See ETHER.

**SULPHUROUS ACID.** See SULPHUR.

**SULPICIANS, or Priests of the Society of St. Sulpice,** a congregation of priests in the Roman Catholic church founded in the parish of St. Sulpice, Paris, in 1645, by Jean Jacques Olier de Verneuil, and specially devoted to the training of candidates for the priesthood. In 1642 Olier and two other clergymen formed a community at Vaugirard, and bound themselves to found ecclesiastical seminaries. His companions soon abandoned him, and becoming in the same year rector of the parish of St. Sulpice, he set about realizing his plan there. The act founding the society of St. Sulpice is dated Sept. 6, 1645, and was immediately sanctioned by the proper authorities. The corner stone of the present seminary of St. Sulpice was laid in September, 1649; the edifice was completed and occupied in August, 1651. The society formed two bands, the one devoted to parish work, the other to that of teaching. The Sulpicians were warmly befriended from the beginning by St. Vincent de Paul, and the establishment of Sulpician seminaries in nearly all the dioceses of France soon followed. Thereby the society came to have the chief part in the education of the French clergy down to the revolution of 1789. They were at first favored by Napoleon, but were suppressed by him in 1812 for their attachment to Pius VII.; they were restored by Louis XVIII., and ever afterward directed the most important diocesan seminaries in France.—Olier in 1636 formed a company for colonizing the island of Montreal. They purchased it in 1640, sent out Sieur de Maisonneuve with priests and nuns in 1641, and transferred their proprietorship to the Sulpicians in 1656. In 1657 the Sulpicians De Queylus, Souard, and Galinier took possession of

the island and founded there a missionary establishment; but their claims to exclusive parochial jurisdiction being resisted, De Queylus in 1659 obtained in Rome a bull erecting Montreal into an independent parish, and used the powers thus conferred in spite of Bishop de Laval, till a *lettre de cachet* forcibly removed him in October, 1660. This conflict of jurisdiction broke out anew in 1821, on the erection of the see of Montreal, and has been kept up till the present time, the most eminent Canadian jurists taking sides in the controversy. Both parties appealed to Rome, and a final decision had not been reached in the beginning of 1876. The Sulpicians François de Fénelon, brother of the author of *Télémaque*, and Claude Trouvé, founded in 1668 the first Iroquois mission at the western extremity of Lake Ontario. In July, 1669, a party of Sulpicians under Dollier de Casson first explored Lake Erie and sailed round it and Lake St. Clair. But their missionary labors were soon necessarily limited to the Indian tribes in the immediate neighborhood of Montreal, where they collected the remnants of the Christian Algonquin and Iroquois tribes into two contiguous settlements at the lake of Two Mountains on the Ottawa. In Montreal city, besides the seminary proper attached to the church of Notre Dame as a parochial residence, founded in 1657, they possess the theological seminary, to which students are sent from every part of the United States, the preparatory seminary or "college of Montreal," founded in 1773, and several other succursal churches with their residences.—In April, 1791, at the call of Bishop (afterward Archbishop) Carroll, a band of four Sulpicians and three seminarians, headed by François Charles Nagot (died 1816), sailed for Baltimore, where they formed for a time the clergy of the cathedral. They sent some of their number to teach in Georgetown college, and founded in Baltimore the theological seminary of St. Mary's, with a collegiate or preparatory school. The seminary was raised by Pope Gregory XVI. to the rank of a Catholic university; the collegiate school was removed to near Ellicott City, Howard co., in 1849, and suppressed in 1852.

**SULPICIUS SEVERUS**, a Roman historian, born near Toulouse about A. D. 363, died at Marseilles about 410. He was a lawyer, but on the death of his wife adopted an ascetic life. His father disinherited him; but, encouraged and assisted by his father-in-law, he formed with his own freedmen and a few followers a monastic establishment near Marseilles. He wrote the life of St. Martin of Tours, an abridgment of the Scriptural narrative, which was a favorite text book in the schools of the middle ages, and a continuation to his own time, under the title of "The Chronicle of Sulpicius Severus." His works, which have been often printed, include also "Three Dialogues" and a collection of letters. The last critical edition is that of Halm, forming vol. i. of the Vienna *Corpus* (1866).

**SUMACH**, or **Sumac** (Arab. *summak*), the common name for plants of the genus *rhus* (the ancient Greek and Latin name), of the cashew family or *anacardiaceæ*, which includes, besides the cashew, the mango and other tropical fruits. The sumachs are represented in the United States by about 12 species, which are shrubs or small trees, with alternate, sometimes simple, but generally trifoliolate or odd-pinnate leaves, and small polygamous flowers in terminal or axillary panicles; the sepals and petals are five, and the stamens, also five, are inserted under the margin of a disk which lines the calyx; fruit a small, dry, nut-like drupe. Our species are separable into several well marked sections or subgenera. 1. The sumachs proper, with pinnate leaves, flowers in a terminal crowded panicle, and the globular fruit clothed with acid hairs; the plants not poisonous, and containing an abundance of tannin. The smooth sumach (*rhus glabra*) is the most common, often covering extensive tracts of barren soil; it grows from 2 to 12 ft. high, with leaves a foot or more long, consisting of 11 to 31 lance-oblong, pointed, serrate leaflets, which are whitish beneath; the yellowish green flowers appear in June, and are pleasantly fragrant; the fruit, in dense clusters, is of the richest crimson, with a velvety appearance from the number of small hairs; it has a pleasant acid taste, due to the presence of a great abundance of bimalate of lime; an infusion of the berries is sometimes used to make a cooling drink in fevers, and as a gargle in affections of the throat and mouth. The leaves of this species are among the first which put on autumn colors, and

Smooth Sumach (Rhus glabra).

show fine tints of yellow and scarlet; a variety in which the leaflets are much subdivided, discovered some years ago in Pennsylvania, is in cultivation for the fern-like beauty of its foliage under the name of cut-leaved sumach. The stag's-horn sumach (*R. typhina*) is the

largest of the northern species, sometimes reaching 30 ft., but is usually about 10 ft.; it is readily distinguished from the preceding by the copious soft velvety down which clothes the ends of the branches; the wood and abundant pith are yellowish or orange-colored; the clusters of fruit, at first crimson, turn purple in autumn; they have the same acid properties as the foregoing. The dwarf or mountain sumach (*R. copallina*) is a remarkably neat shrub, seldom more than 6 or 8 ft. high; the branches are downy, but less conspicuously so than in the stag's-horn sumach, and it is readily distinguished from either of the others by its dark shining leaves, the common petiole to which bears a winged margin; the leaves in autumn turn to a rich purple; fruit similar to the preceding. A very dwarf species of this section, *R. pumila*, with branches only about a foot high, is found from North Carolina southward in pine barrens; this has been erroneously described as poisonous. 2. The section *lobadium* includes species in which the flowers are in short ament-like spikes preceding the leaves, fruit flattish, and leaves of three leaflets, not poisonous. The principal species is the fragrant sumach (*R. aromatica*), a straggling bush 4 or 5 ft. high; its range is from Vermont to Florida, and westward to the Rocky mountains, where it has smaller leaves and has been described as a distinct species (*R. trilobata*). The leaves of the eastern form are pleasantly fragrant when bruised, and those of the western have a strong and heavy odor; they with other leaves form the kinnikinick or killikinick, smoked by the Indians as a substitute for tobacco. 3. The section *cotinus* has simple leaves, not poisonous, and flowers in loose panicles. This is represented by the well known Venetian sumach, or smoke tree of the gardens (*R. cotinus*), sometimes

Venetian Sumach (Rhus cotinus). Fruitful and abortive pedicels, reduced and of full size.

called by nurserymen the purple fringe tree; it is a native of southern Europe, and is rarely over 10 or 12 ft. high; in summer it is nearly enveloped in large, feathery, cloud-like masses, which are at first greenish and later tinged with red; this very showy effect is produced by the little pedicels or stalks of the flower cluster, very few of which bear flowers and fruit, while the abortive ones lengthen greatly, branch, and become plumose with long hairs. This plant was known to the ancients, and has long been used in Greece and other countries for tanning and dyeing. A tree closely resembling this, found in the interior of Alabama, and described by Nuttall as a distinct species (*R. cotinoides*), is so little known that it is not yet admitted as really different. 4. The *toxicodendron* group includes two species with white or dun-colored berries in loose panicles and highly poisonous foliage. The

Poison Ivy (Rhus toxicodendron).

poison ivy or poison oak (*R. toxicodendron*) is also in some localities called mercury vine; it has leaves of three leaflets, which are rhombic ovate, and variously notched, lobed, or even entire; its flowers are in loose slender axillary panicles; the smooth fruit is pale brown. This is found nearly all over the country, especially in moist and shady places, and presents two forms, one erect and the other climbing, which were formerly described as distinct species, but run into one another in such a manner that they can hardly be regarded as varieties; it clambers over rocks and fences, and by means of aërial rootlets ascends the trunks of the tallest trees, and adheres with great pertinacity; when wounded it exudes a milky juice, which becomes black upon exposure to the air, and upon fabrics makes a stain indelible by all ordinary solvents; the leaves taken internally promote the secretions of the skin and kidneys. This plant is highly poisonous to many persons. The poison sumach (*R. venenata*), also often called poison dogwood and poison elder, is an exceedingly neat and graceful shrub, 6 to 18 ft. high, found in swamps from Canada to Louisiana; the young shoots are purple, or green clouded

with purple, and marked by orange-colored dots which turn grayish; the leaves have 7 to 13 leaflets, which are dark green, pointed, and entire on the margins; the greenish yellow

Poison Sumach (Rhus venenata).

flowers are in loose axillary panicles, and the greenish white fruit hangs in loose clusters on stems 6 or 8 in. long, and remains after the leaves have fallen; the juice is milky, and dries to a black varnish. This has poisonous characters similar to the preceding, but is much more virulent. The susceptibility to the poison varies greatly in different persons; many can handle the plants without any unpleasant results, while others are seriously affected by touching them, or even passing near them. The poisonous properties of these plants are due to a volatile acid named by its discoverer, Prof. J. M. Maisch, toxicodendric. Its effect is an acute eczematous inflammation of the skin, often accompanied by much swelling. The usual remedies are cooling saline purgatives and an external application of lead water. The coral sumach (*R. metopium*), a native of the West Indies, is found in the southernmost parts of Florida; it is a tree 15 to 20 ft. high, with leaves of three to seven thick leaflets, and loose clusters of scarlet berries the size of peas; this also is poisonous.—The sumach of commerce formerly consisted entirely of the imported leaves of *rhus coriaria* of southern Europe and northern Africa; it greatly resembles in appearance our stag's-horn sumach (*R. typhina*), and like that forms a small tree; it is largely cultivated in Sicily, where the suckers are planted in rows about 4 ft. apart, and the shoots are yearly cut back to within a few inches of the ground, the crop for the next year being furnished by the new stems which push from the stumps; the shoots are dried and threshed, the leaves are finally ground between mill stones and bolted, and the powder is put into sacks of 163 lbs. each for shipment; the product is sometimes adulterated with other leaves, but when pure contains from 30 to 35 per cent. of tannin. Sumach is used for tanning light-colored leathers and in dyeing and calico printing; it yields with different mordants a great variety of tints. Since the civil war the collection and preparation of the leaves of our native sumachs have assumed considerable importance, especially in Virginia, the headquarters of the industry being at Richmond. The plants grow so abundantly in the wild state that cultivation has not been attempted; the smooth, the stag's-horn, and the mountain sumachs are collected indiscriminately, but as the first named is the most abundant, the product consists mainly of that; the gathering begins early in July and continues till frost. The leafy tops of the plants are broken off and carefully dried, the best being that dried in the shade; when dry it is beaten with sticks, and the leaves are taken to the mill to receive the same treatment as that described for Sicilian sumach. American sumach contains from 15 to 20 per cent. or more of tannin.—The Japan wax, or vegetable wax of Japan, is yielded by *rhus succedanea*, being found as a thick white coating of the seed within the capsule. To extract it, the bruised seed vessels are boiled in water and the wax skimmed off as it rises to the top; it has much the appearance of white wax (bleached beeswax), but is rather more opaque; it melts at about 127°, saponifies readily, and formed into candles gives a fine clear light; mixed in proper proportions with paraffine, it makes a candle in appearance closely resembling one of wax.—The lacquer of the Japanese is produced by *R. vernicifera*, a shrub so nearly like our poison sumach in appearance and in poisonous qualities that the two were at one time supposed to be identical. The juice, obtained by wounding the tree, is at first milky, but becomes black on exposure, and is largely used for furniture and various kinds of woodwork. Americans in Japan have become seriously poisoned by coming in contact with newly varnished wares. Dr. Jacob Bigelow many years ago demonstrated that our poison sumach affords a similar product. Other and poisonous species afford lacquer to the

Chinese Galls (Rhus semialata).

natives of China and India.—The singularly shaped Chinese galls are the result of the puncture and deposition of the egg of an insect in the leaf stalks and young shoots of a sumach,

*rhus semialata*, of northern India, China, and Japan; the galls are very irregular in shape, 1 to 2½ in. long, mostly egg-shaped, with various knotty protuberances, and often lobed, velvety with a gray down; they are more brittle shells about $\frac{1}{20}$ in. thick, breaking with a shining fracture, and containing about 70 per cent. of tannin. In 1872, 8,621 cwt. of these galls were imported into Great Britain alone.

**SUMAROKOFF, Alexei Petrovitch**, a Russian dramatist, born in Moscow in November, 1727, died there in October, 1777. He was educated at St. Petersburg, and the empress Elizabeth placed him in the school of cadets. In 1756 he founded the first national theatre at St. Petersburg, and became its director with the rank of brigadier general. Catharine II. made him councillor of state. He modelled his plays after Corneille, Racine, and Voltaire. Among his tragedies are *Khoreff* and *Sinaff i Truvor.* He also wrote prose works, satires, and other poetry. His complete writings (10 vols., 1787) have passed through several editions.

**SUMATRA** (Sans. *Samudra*, the ocean), an island of the Indian archipelago, in the Indo-Malay group, lying directly under the equator, S. W. of the Malay peninsula and parallel to it, between lat. 5° 40′ N. and 5° 55′ S., and lon. 95° 20′ and 106° 5′ E.; bounded N. by the bay of Bengal, N. E. by the strait of Malacca, E. by the China sea, the strait of Banca, and the Java sea, S. by the strait of Sunda, and S. W. by the Indian ocean; extreme length 1,050 m., greatest breadth 250 m.; area, 160,000 sq. m.; pop. estimated at from 3,000,000 to 4,000,000. About three fourths of the island is subject to the Netherlands, a portion directly, and the rest through dependent native rulers. To the first class belong four colonial establishments, which include the adjoining islands: 1. The government officially known as Sumatra's West Coast, comprising the western seaboard from lat. 2° 30′ N. to 1° 55′ S., and including the residencies of Tapanuli and Padang; aggregate area, about 47,000 sq. m.; pop. in 1872, 1,620,979. 2. Bencoolen, on the S. W. coast, described under its own title. 3. Lampong, at the S. extremity of the island; area, 10,000 sq. m.; pop. 112,271. 4. Palembang, on the S. E. coast opposite Banca. (See Palembang.) The principal native state in Sumatra is Acheen, which embraces the northern end of the island from coast to coast, and is wholly independent of the Dutch. (See Acheen.) The territory of the cannibal Bataks extends southward from Acheen, along the interior, to the border of the colonial districts of the W. coast. The largest native countries in the east are Siak, opposite the S. extremity of Malacca, and Jambi, between Siak and the Dutch residency of Palembang.—The physical conformation of Sumatra resembles that of Java in the long volcanic range which extends throughout the island, although the active volcanoes are not nearly so numerous, and probably do not exceed five. The range is near the W. coast, from which it is separated by a strip of lowlands from less than 20 to 30 m. wide, above which the mountains rise abruptly to a height of from 2,500 to 5,000 ft., with many lofty peaks. They form four or five parallel ridges with elevated plateaus between them. There are four summits over 10,000 ft. high, and six others over 5,000 ft. Mt. Berapi, just S. of the equator (12,000 ft.), is the centre of a volcanic district containing numerous hot springs, and continually emits vapor. The altitude of Mt. Ophir (or Passaman peak), at the equator, and Mt. Indrapura, in lat. 1° 30′ S., is estimated at upward of 12,000 ft., and a height of 11,000 ft. is assigned to the Abong-Abong mountain, which rises from the very centre of the unexplored interior of Acheen. The portion of Sumatra which lies eastward of the great linear volcanic range is a vast low and comparatively level forest region, watered by numerous and extensive rivers, and subject to frequent inundation near the coast. The formation of this great plain is alluvial, and comparatively recent in geological time, while the W. coast is believed to be gradually wearing away. According to Wallace, Sumatra was formerly connected with the Malay peninsula, and also with Borneo. In western Sumatra the underlying formation consists of granite and syenite, overspread with mud and coral, sandstone, and lava and other volcanic products. Limestone and marble occur in Padang, and there are extensive coal beds in the island, but of very recent origin. Sumatra has long been noted for its yield of gold, which is still considerable, being derived from the beds of the rivers, particularly the Indragiri, the Jambi, and their tributaries. Iron, copper, tin, sulphur, and petroleum are also found.—The coast is about 2,500 m. in circuit. The island terminates on the northwest in Acheen head and on the northeast in Diamond point. Between these points stretches the N. coast of Acheen, formerly known as the Pedir coast, on which is the town of Passier, believed to be the first place to which the name *Samuthrah* (Sumatra) was applied. The shore is high and bold, and the anchorage is mostly in open roadsteads. The N. E. coast is low, and from the narrowest part of the strait of Malacca southward to the strait of Sunda it is bordered by extensive banks of mud and sand, making navigation intricate and dangerous. The entire W. coast is exposed to a very heavy surf, and more especially that portion which lies S. of the equator. It is indented by several excellent harbors, that of Tapanuli being considered one of the finest in the world. Parallel to it and about 60 m. distant is a chain of islands, between lat. 3° N. and 5° 30′ S., comprising several of considerable size, including Pulo Babi or Hog island (50 m. long), Pulo Nias (70 m.), Sibiru, Sipora, the Poggi islands, and Engano. Most of them are high, well wooded, and thickly inhabited. The chief islands off the E. coast

are Banca and Rupat, the latter in lat. 2° N., extending about 25 m. each way, and separated from Sumatra by a narrow strait, only navigable by small vessels.—The large rivers of Sumatra flow down the eastern watershed, and although there are many rivers on the W. coast, they all have short courses and are very rapid. The principal eastern watercourses are the Rakan, flowing northward from the equator; the Siak, 200 m. long, in the native state of Siak; the Kamper, still further S.; the Indragiri, having a general eastward course not far from the 1st parallel of S. latitude, and said to be 300 m. long; the Jambi, in the country of that name; and the Musi or Palembang, falling into the strait of Banca, the largest river in Sumatra and navigable 200 m. inland. In the lower part of their courses these rivers are very sluggish, and they all have extensive deltas. Among the mountains in the west are several lakes, of which the best known is Sinkara, nearly 1° S. of the equator, at a height of 1,700 ft. above the sea. It is 10 m. long, 3 m. broad, and 1,182 ft. deep. The Manindyu lake, in the same region, occupies the elliptic crater of an extinct volcano, and is 6 m. long by 4 m. in width, with a depth of 2,060 ft.—The climate of Sumatra is warm and moist, the thermometer ranging throughout the year between 76° and 93°. There are about 200 days of rain in the year on the Padang plateau, 2,400 ft. above the ocean. During the N. W. monsoon, which blows from November to January, the weather is excessively rainy; but from June to September, when the S. E. monsoon prevails, the rainfall is limited to showers. Except in the marshy districts, the coasts are moderately healthful. Sumatra is overspread with vast forests, rich in the most valuable products of the tropics. Much of the E. coast is covered with mangrove bushes. Further inland are found palms, and trees of gigantic growth, many of them being more than 100 ft. high. On the W. shore, besides the myrtle and several varieties of fig, all the fruit trees common to the archipelago abound, and most of the mountains are covered to their summits with jungle. In the forests are many valuable timber trees, immense tree ferns, bamboos, rattans, the camphor tree, caoutchouc, and benzoin. The parasitic *Rafflesia* bears a flower with a calyx a yard in diameter. The soil of Sumatra is remarkable for its fertility, and yields large and valuable crops of rice, coffee, pepper, and tobacco, and some cotton. The cocoanut tree, the betelnut, and the sago palm also afford important products. There is a considerable export of coffee to the United States from Padang, where it is grown on the plateau. In Acheen pepper is the chief crop.—The Sumatran fauna corresponds closely with that of Java and Borneo, the other great islands of the Indo-Malay group. Of the quadrumana it comprises 11 species, among them the siamang ape, and the orang-outang, whose sole other habitat is Borneo; it is believed to be confined to the N. W. portion of Sumatra. The tiger, the two-horned rhinoceros, and the elephant (*E. Sumatranus*) are all found on the island. Many elephants were tamed in former times, but no attempt is now made to domesticate them. Other mammals are the musk deer and great Malay deer, the tapir, the flying lemur, the Malayan sun bear, squirrels, and bats. There are many beautiful pheasants, parrots, partridges, woodpeckers, herons, and the large hornbill. Crocodiles and pythons are the most formidable reptiles. The forms of insect life are numerous and varied, including 21 *papilionidæ*, among which is the leaf butterfly. In many parts of the island travelling is rendered uncomfortable by swarms of leeches and mosquitoes. Buffaloes, horses, goats, and Chinese pigs are the common domestic animals.—The inhabitants of Sumatra are of the Malay race, of which the island is supposed to have been the cradle. They are divided into several tribes, who speak languages that are considered as dialects of one common tongue. There are tribes in the interior whose origin is involved in obscurity. The people of the N. part of Sumatra, about Acheen, are taller, stouter, and of darker complexion than the other tribes, and are supposed to have a considerable infusion of Hindoo blood. The Bataks or Battas, who occupy the country immediately S. of these people, are smaller and of lighter complexion, and in some respects a very singular race. (See Batak.) Mohammedanism is the prevailing religion, but it is in a relaxed state, and the people of the interior cannot be said to belong to any particular faith. Polygamy is not common except among the chiefs. The Malays round the coast appear to be collected from different parts of the archipelago, and it is estimated that more than 6,000 Chinese have settled in the Dutch possessions. Among the natives the ordinary dress is a turban and loose trowsers reaching to the knee; the upper part of the body is commonly uncovered in both sexes, but a scarf is sometimes worn about the shoulders. The houses are raised on posts or pillars from 4 to 8 ft. from the ground, and in some parts of the country they are erected in trees. Those of the poorer classes are made of bamboo and thatched with grass, but the houses of the more wealthy are generally framed of wood and the sides enclosed by large sheets of bark. Agriculture is in a very rude state. The only important manufactures are of utensils and cloth for domestic purposes. Iron for native use is now wholly imported. The trade of Sumatra is principally carried on with Java, Madura, Singapore, Malacca, Penang, and British India. The chief exports are pepper, gold dust, camphor, nutmegs, cloves, mace, benzoin, gutta percha, copper, tin, sulphur, and coral. —For administrative purposes the Dutch colonial possessions are divided into districts, each under a controller, who visits the various villages from time to time. The native inhabi-

tants are forbidden to bear firearms. The entire number of Europeans in the country probably does not exceed 2,000. The chief towns are Acheen in the north, Palembang in the southeast, Bencoolen in the southwest, and Padang on the W. coast.—The first historical notice of Sumatra occurs in Arab manuscripts narrating voyages made thither in the 9th century. The island was visited in 1292 by Marco Polo, who described it very accurately under the name of Java the Less. It began to be known to foreigners as Sumatra in the last half of the 14th century. Before the middle of the 15th century it was reached by the Venetian traveller Nicolò di Conti. The Portuguese first arrived there in 1509, visiting the Acheen coast, where they found a powerful king, who effectually opposed their efforts to obtain a footing. The hostilities thus begun between Portugal and Acheen continued with but little intermission till 1641, when the Portuguese lost Malacca. Sumatra was first visited by the Dutch in 1599 and by the English in 1602. The Dutch formed a settlement at Padang in 1649, got possession of some districts in the S. part of the island, and established several factories. In 1795 all their Sumatran territories fell into the hands of the English, who had established a station at Bencoolen in 1685. They were restored in 1815, but Bencoolen was retained till 1824, when all the British possessions in Sumatra were ceded to the Netherlands in exchange for Malacca and small settlements upon the coasts of India. The Dutch have since found means to annex a great extent of territory. At the time of the treaty of 1824, the Dutch government pledged itself not to assail Acheen, but for many years the prevalence of piracy and the ill treatment of foreign vessels on the N. coast have led to much complaint. All objections on the part of Great Britain to the extension of Dutch rule in Sumatra were removed by a treaty made in 1871, and in consequence of repeated violations of faith on the part of the sultan of Acheen, a naval and military expedition was despatched from the Netherlands to the N. coast of Sumatra in 1873. It was repulsed by the Acheenese with heavy loss, and the war has since been carried on with varying success.

**SUMBAWA,** an island of the Indian archipelago, in the Sunda chain, lying between Flores on the east and Lombok on the west, the S. W. point in lat. 9° 2′ S., lon. 116° 42′ E.; length E. and W. about 170 m., extreme breadth 50 m.; estimated area, 6,000 sq. m.; pop. about 80,000. Wallace classifies it zoölogically in the Timor group. A deep bay penetrates the N. coast, and it is separated from Flores by Sapi and Mangerai straits, between which lies the island of Comodo. Sumbawa is divided into six native states, each governed by a rajah who acknowledges the supremacy of the Dutch. They are Tomboro and Sumbawa on the N. coast, Bima on the E. coast, where the Dutch have a resident, and Dompo, Sangar, and Papakat. The island is mountainous, and lies within the volcanic belt of the Indian archipelago, containing Mt. Tomboro, a volcano near the N. coast, 8,940 ft. high, the eruption of which in 1815 caused a subsidence of the surface, and was characterized by tremendous explosions which were heard over an area having a radius of more than 800 m. Nearly 12,000 persons were killed; the ashes fell in Java and Flores to the depth of several inches, and even in Sumatra, 840 m. from the volcano. In Lombok immense damage was done and many lives were lost. In 1836 a less destructive eruption occurred. Gold, sulphur, and saltpetre are found. Sumbawa is not well wooded, but sandal and sapan wood and teak occur to a limited extent. Its horses, among the best in the archipelago, are largely exported. The pearl oyster is found. The manners and language of the natives strongly resemble those of the inhabitants of Celebes. The island has been subject to the Dutch since 1676.

**SUMBUL.** See p. 900.

**SUMMER,** the warm season of the year, including astronomically the time between the vernal and autumnal equinoxes, or from about the 21st of June till about the 22d of September. The calendar summer comprises in the United States the months of June, July, and August; in England, May, June, and July. In the southern hemisphere the summer months are December, January, and February according to the American method of regarding the seasons, or November, December, and January according to the English method. Between the tropics there is no summer properly so called, the hottest times being those when the sun passes to the zenith at noon, which at the equator will correspond to the vernal and autumnal equinoxes, the two dates being on our summer side of the equinoxes for places N. of the equator, and on our winter side in places S. of the equator.—The Indian summer is a period of warm, pleasant weather, which usually occurs every year over the northern portion of the United States after the autumnal storms, and continues often without interruption two or three weeks. It appears to be a more decided season in the interior than near the coast, and in the region of the great lakes is especially noticeable, the waters during its continuance remaining placid, and the atmosphere filled with a peculiar haziness. The Indians regarded it as the gift of their most honored deity, the god of the southwest, who sends the S. W. winds, and to whom they believed their souls to go after their decease.

**SUMMERFIELD, John,** an American clergyman, born in Preston, England, Jan. 31, 1798, died in New York, June 13, 1825. He was educated at a Moravian school, removed to Dublin in 1813, joined the Wesleyan society at the age of 19, and became a preacher. In 1821 he removed to New York, where his eloquence drew crowds to hear him. In 1822 he visited Philadelphia, Baltimore, and Wash-

ington, and in December went to Paris, and then to England. In 1824 he returned to New York, and continued for a time to travel and preach. He was a founder of the American tract society. His biography has been written by John Holland (8vo, New York, 1829), and by William M. Willett (Philadelphia, 1857). His "Sermons and Sketches of Sermons" were published at New York in 1842.

**SUMMER RED BIRD.** See TANAGER.

**SUMMERS,** a central county of West Virginia, bounded S. W. by the Meadow river, and intersected by Gauley river. It has been formed since the census of 1870 from Nicholas co. The surface is greatly diversified, and the valleys are productive. The staples are wheat, corn, oats, hay, and dairy products. Capital, Hinton.

**SUMMERS, Thomas Osmond,** an American clergyman, born near Corfe Castle, Dorsetshire, England, Oct. 11, 1812. He emigrated to the United States in 1830, and became a preacher of the Methodist Episcopal church, at first in Virginia. In 1840 he went to Texas as one of nine ministers to constitute the first conference there. In 1844 he joined the Alabama conference, and as secretary of the convention at Louisville, Ky., assisted in organizing the Methodist Episcopal church, South. By appointment, he assisted in editing the "Southern Christian Advocate" and in compiling a new hymn book. In 1850 the general conference elected him editor of their books and tracts, and of the "Sunday School Visitor," and in 1858 also of the "Quarterly Review." In 1866 he was elected editor of the "Nashville Christian Advocate," and in 1874 professor of systematic theology in the new Vanderbilt university, Nashville, Tenn. His writings include "Commentaries on the Gospels and on the Acts of the Apostles;" "Commentary on the Ritual of the M. E. Church, South;" "A Treatise on Baptism;" "A Treatise on Holiness;" "Sunday School Teacher, or the Catechetical Office;" "Seasons, Months, and Days;" "Talks Pleasant and Profitable;" "The Golden Censer;" "Scripture Catechism" (2 vols., Old and New Testament); "Refutation of Thomas Paine's Theological Writings;" and an enlargement and revision of Watson's "Biblical and Theological Dictionary."

**SUMMIT. I.** A N. E. county of Ohio, drained by the Cuyahoga river and the head streams of the Tuscarawas, and traversed by the Ohio canal and several railroads; area, 400 sq. m.; pop. in 1870, 34,674. It is the most elevated land on the line of the Ohio canal. The surface is uneven and the soil highly fertile. Coal is mined in large quantities. Water power abounds. The chief productions in 1873 were 307,123 bushels of wheat, 633,619 of Indian corn, 386,714 of oats, 98,489 of potatoes, 32,587 tons of hay, 105,639 lbs. of wool, 749,370 of butter, and 1,586,842 of cheese. In 1874 there were 8,223 horses, 23,911 cattle, 28,065 sheep, and 9,594 hogs. In 1870 there were 5 manufactories of agricultural implements, 10 of brick, 23 of carriages and wagons, 11 of cheese, 16 of cooperage, 1 of cutlery and edge tools, 1 of anchors and chains, 8 of iron castings, 9 of tanned and 6 of curried leather, 7 of machinery, 3 of paper, 26 of stone and earthen ware, 3 of woollen goods, 10 flour mills, and 15 saw mills. Capital, Akron. **II.** A N. W. county of Colorado, bordering on Utah, and watered by the Grand, White, and Bear rivers; area, about 8,500 sq. m.; pop. in 1870, 258. This county formerly occupied the whole N. W. corner of the territory W. of the Rocky mountains, but in 1874 Grand co., with an area of about 11,000 sq. m., was formed from the N. portion. The E. includes a portion of the Middle park, and is crossed by the Rocky mountains. The W. portion is densely timbered with pine and spruce, and there are immense beds of coal. Gold, copper, lead, iron, and zinc are found. On the Grand and Blue rivers and their tributaries are good grazing lands; little is known of the agricultural capabilities of the county. The population is chiefly in the S. E. corner, on the head waters of the Blue river, and is almost exclusively engaged in gold placer mining. Capital, Breckinridge. **III.** A N. E. county of Utah, bordering on Wyoming, and containing the head waters of Bear and Weber rivers; area, 1,250 sq. m.; pop. in 1870, 2,512. It is crossed by the Union Pacific railroad. The surface is mountainous. Coal, gold, silver, and lead are found. The chief productions in 1870 were 18,955 bushels of wheat, 2,028 of oats, 1,352 of barley, 12,149 of potatoes, 13,540 lbs. of butter, and 2,569 tons of hay. The value of live stock was $65,353. Capital, Coalville.

**SUMNER. I.** A N. central county of Mississippi, formed in 1874 from Choctaw, Montgomery, and Oktibbeha counties; area, 408 sq. m.; pop. about 8,000. It is drained by the Big Black river. The surface is somewhat undulating and the soil productive. The chief crops are Indian corn, sweet potatoes, and cotton. Capital, Mt. Tabor. **II.** A N. county of Tennessee, bordering on Kentucky, bounded S. by the Cumberland river and drained by affluents of Big Barren river; area, about 500 sq. m.; pop. in 1870, 23,711, of whom 7,777 were colored. The surface is undulating and the soil fertile. The Louisville, Nashville, and Great Southern railroad passes through it. The chief productions in 1870 were 163,114 bushels of wheat, 1,155,914 of Indian corn, 233,837 of oats, 35,253 of Irish and 25,074 of sweet potatoes, 4,921 tons of hay, 909,568 lbs. of tobacco, 38,860 of wool, 224,295 of butter, 15,668 of honey, and 38,563 gallons of sorghum molasses. There were 7,582 horses, 3,078 mules and asses, 5,378 milch cows, 9,500 other cattle, 20,421 sheep, and 37,304 swine. Capital, Gallatin. **III.** A S. county of Kansas, bordering on Indian territory, and intersected in the northeast by the Arkansas river; area, 1,152 sq. m.; pop. in 1870, 22; in 1875, 4,925. It consists of fertile prairies. Capital, Sumner.

**SUMNER, Charles,** an American statesman, born in Boston, Mass., Jan. 6, 1811, died in Washington, D. C., March 11, 1874. His father, who died in 1839, was a graduate of Harvard college, a lawyer, and for 14 years high sheriff of the county of Suffolk. The son received his early education at the Boston Latin school, and graduated at Harvard college in 1830. He was appointed reporter of the circuit court of the United States, in which capacity he published three volumes known as "Sumner's Reports," containing decisions of Judge Story. He also at the same time edited the "American Jurist," a quarterly law journal of high reputation. During the first three winters after his admission to the bar, while Judge Story was absent in Washington, Mr. Sumner was appointed lecturer to the law students, and part of the time he had sole charge of the school. His favorite topics were those relating to constitutional law and the law of nations. He visited Europe in 1837, travelled in Italy, Germany, and France, and resided for nearly a year in England. He carried to England a letter of introduction from Judge Story, in which he was described as "a young lawyer giving promise of the most eminent distinction in his profession, with truly extraordinary attainments, literary and judicial; and a gentleman of the highest purity and propriety of character." He was received with unusual distinction in the highest circles, was introduced by eminent statesmen on the floor of the houses of parliament, and invited by the chief judges to sit with them in Westminster hall. He returned to Boston in 1840, and in 1844-'6 published an elaborate edition with annotations of "Vesey's Reports" in 20 vols. Though voting with the whig party, he took no active part in politics till 1845, when on the 4th of July he pronounced before the municipal authorities of Boston an oration on "The True Grandeur of Nations," in which, prompted by the menacing aspect of affairs between the United States and Mexico, he denounced the war system as the ordeal by battle still unwisely continued by international law as the arbiter of justice between nations, and insisted that this system ought to give way to peaceful arbitration for the adjudication of international questions. His oration attracted unusual attention, led to much controversy, and was widely circulated both in America and Europe. It was followed by a rapid succession of public addresses on kindred themes, which were also widely circulated. Mr. Sumner earnestly engaged in the opposition to the annexation of Texas on the ground of slavery. In 1846 he made an address to the whig state convention of Massachusetts on "The Anti-Slavery Duties of the Whig Party," and shortly afterward published a letter of rebuke to Mr. Robert C. Winthrop, who then represented Boston in congress, for his vote in favor of the war with Mexico. These steps led eventually to Mr. Sumner's separation from the whig party and association with the freesoilers, to whose candidates, Van Buren and Adams, he lent efficient support in the presidential contest of 1848. After the withdrawal of Mr. Webster from the senate of the United States by his entrance into the cabinet of Mr. Fillmore in 1850, Mr. Sumner was nominated for the vacancy by a coalition of freesoilers and democrats in the Massachusetts legislature, and was elected on April 24, 1851, after a most earnest and protracted contest. He took his seat on Dec. 1, 1851, and retained it by successive reëlections till his death. His first important speech was upon the fugitive slave act, against which he argued that congress had no power under the constitution to legislate for the rendition of fugitive slaves; and that if it had, the act in many essential particulars conflicted with the constitution, and was also cruel and tyrannical. In this speech Mr. Sumner laid down as a guide for political action the formula to which he ever afterward adhered, that "freedom is national and slavery sectional." In the debate on the repeal of the Missouri compromise and on the contest in Kansas, Mr. Sumner took a very prominent part. His last speech upon this topic, which was printed under the title of "The Crime against Kansas," occupied two days in its delivery, May 19 and 20, 1856. Some passages in it greatly incensed the members of congress from South Carolina, one of whom, Preston S. Brooks, on May 22 assaulted Mr. Sumner while he was writing at his desk in the senate chamber, and with a gutta percha cane struck him on the head till he fell to the floor insensible. (See Brooks, Preston S.) The injury thus received proved very serious, and was followed by a severe and long disability, from which his recovery was not complete till three or four years later. His term of office as senator expired March 4, 1857, and in the preceding January the legislature of Massachusetts reëlected him by a unanimous vote in the senate, while in the house of representatives, consisting of several hundred members, he received all but seven votes. Under the advice of physicians he went to Europe for the benefit of his health in March, 1857, and returned in the autumn to resume his seat in the senate. His health being still impaired, he went abroad again in May, 1858, remaining till the autumn of 1859, and submitted to a course of extraordinarily severe medical treatment in Paris. His next serious effort was an elaborate speech in the senate, denouncing the influence of slavery on character, society, and civilization, which was printed under the title of "The Barbarism of Slavery." In the presidential contest of 1860 he made several speeches in behalf of Abraham Lincoln and Hannibal Hamlin. In the senate and in popular addresses during the civil war he earnestly opposed all concession to or compromise with slavery, and early proposed emancipation as the speedi-

est mode of bringing the war to a close. He based his arguments not only on moral and historical, but on constitutional grounds, and always claimed that his positions were in strict accordance with the constitution of the United States. In March, 1861, when the republican party obtained the control of the senate, Mr. Sumner was made chairman of the committee on foreign relations. On Jan. 9, 1862, he delivered an elaborate speech arguing that the seizure of Messrs. Mason and Slidell on board the steamer Trent was unjustifiable on the principles of international law which had always been maintained by the United States. This speech had great influence in reconciling the public to the surrender of the confederate envoys. Later in the war he made powerful speeches on "Our Foreign Relations" (1863), and on "The Case of the Florida" (1864), and in 1865 he pronounced a eulogy on President Lincoln. A speech upon our claims on England, April 13, 1869, caused great excitement and indignation in Great Britain, where it was erroneously supposed to threaten war and regarded as an attempt to excite popular feeling against that country by exaggerating the "consequential damages" she had incurred in recognizing the belligerency of the seceding states and in allowing the confederate cruisers to sail from her ports. In the same year his opposition to the Santo Domingo treaty, against which he delivered a speech in the senate, brought him into collision with the administration of President Grant, and led to his removal in March, 1870, from the chairmanship of the committee on foreign relations, and ultimately to his separation from the republican party and his support of Horace Greeley, the liberal republican and democratic candidate for president in 1872. In the spring of that year he had delivered in the senate an animated speech against the renomination of President Grant, which did not have the weight he expected with the republican convention that met shortly afterward. On Sept. 11 a convention of democrats and liberal republicans, held at Worcester, Mass., nominated him for governor of the state; but he had already gone to Europe for medical advice, and when the news of his nomination reached him in England he declined it. He returned from Europe late in 1872, and on taking his seat in the senate reintroduced two measures which he had unsuccessfully proposed before. One was the civil rights bill, the other a resolution providing that the names of the battles won over fellow citizens in the civil war should be removed from the regimental colors of the army and from the army register. This last resolution was strongly denounced, and led to a vote of censure on him by the legislature of Massachusetts in 1873, which was rescinded in 1874, shortly before his death. He died of angina pectoris, after an illness of a few hours. Mr. Sumner's addresses were first collected under the title of "Orations and Speeches" (2 vols. 12mo, Boston, 1850), to which was added "Recent Speeches and Addresses" (12mo, Boston, 1856). During the last years of his life he prepared a final and complete collection entitled "The Works of Charles Sumner" (12 vols., Boston, 1871-'5). Two or three more volumes are to appear, under the charge of his executors, of whom the chief is Prof. Longfellow.—See "A Memorial of Charles Sumner," published by order of the legislature of Massachusetts (Boston, 1874), and "Life and Public Services of Charles Sumner," by C. Edwards Lester (New York, 1874).

**SUMNER, John Bird,** an English clergyman, born at Kenilworth, Warwickshire, in 1780, died in London, Sept. 6, 1862. He graduated at Cambridge, and in 1820 became canon of Durham, in 1828 bishop of Chester, and in 1848 archbishop of Canterbury. He was a leader of the evangelical school in the church of England, and while he was primate of England occurred the controversy about the work entitled "Essays and Reviews," and also the revival of the synodical power of the convocations. He published an essay on "Apostolical Preaching" (London, 1815); "The Records of Creation" (2 vols., 1816), which won the second Burnet prize of £400; "Evidences of Christianity" (1824); and a volume of selections entitled "Practical Reflections" (1859).

**SUMTER,** the name of four counties in the United States. **I.** An E. county of South Carolina, bounded W. by the Wateree river, and drained by Black river and its affluents; area, about 900 sq. m.; pop. in 1875, 31,480, of whom 23,086 were colored. The surface is generally undulating and the soil fertile, and there are extensive forests of pine. It is intersected by the Wilmington, Columbia, and Augusta railroad and its branch. The chief productions in 1870 were 189,039 bushels of Indian corn, 36,113 of sweet potatoes, 7,212 bales of cotton, 245,325 lbs. of rice, and 2,282 tons of hay. There were 905 horses, 1,126 mules and asses, 1,699 milch cows, 2,630 other cattle, 1,075 sheep, and 658 swine; 6 manufactories of carriages and wagons, 4 of tar and turpentine, and 5 saw mills. Capital, Sumter Court House. **II.** A S. W. county of Georgia, bounded E. by Flint river; area, about 600 sq. m.; pop. in 1870, 16,559, of whom 10,639 were colored. The surface is level and the soil fertile. It is traversed by the Southwestern railroad. The chief productions in 1870 were 280,379 bushels of Indian corn, 22,085 of oats, 11,516 of peas and beans, 40,924 of sweet potatoes, 12,823 bales of cotton, 61,031 lbs. of butter, and 15,310 gallons of molasses. There were 634 horses, 1,796 mules and asses, 1,768 milch cows, 3,878 other cattle, 832 sheep, and 12,624 swine. Capital, Americus. **III.** A central county of Florida, bounded W. by the Withlacoochee river; area, 1,370 sq. m.; pop. in 1870, 2,952, of whom 980 were colored. The surface is generally level and swampy, and there are several small lakes.

The chief productions in 1870 were 67,278 bushels of Indian corn, 112,620 of sweet potatoes, 8,800 lbs. of rice, 501 bales of cotton, and 13,650 gallons of molasses. There were 14,995 cattle and 5,480 swine. Capital, Leesburg. **IV.** A W. county of Alabama, bordering on Mississippi, bounded E. by the Tombigbee and intersected by the Noxubee river; area, about 800 sq. m.; pop. in 1870, 24,109, of whom 18,907 were colored. The surface is uneven and the soil fertile. It has water communication by the Tombigbee river, and is intersected by the Alabama and Chattanooga railroad and a branch of the Mobile and Ohio. The chief productions in 1870 were 334,110 bushels of wheat, 14,941 of sweet potatoes, 2,513 lbs. of wool, and 11,646 bales of cotton. There were 1,242 horses, 1,957 mules and asses, 2,097 milch cows, 988 working oxen, 3,644 other cattle, 2,249 sheep, and 8,024 swine. Capital, Livingston.

**SUMTER, Fort,** a work built upon an artificial island near the entrance of the harbor of Charleston, S. C., which it was designed to protect. It stands about 2¾ m. from Castle Pinckney, the fort near the point of the peninsula upon which Charleston is built, and about half that distance from Fort Moultrie on Sullivan's island. It was intended to mount 140 heavy guns, in three tiers; but at the close of 1860 the fort was still incomplete, few of the guns being mounted. The United States garrison, numbering 109 men, of whom only 63 were combatants, under Major Robert Anderson, occupied Fort Moultrie. On the night of Dec. 26 Major Anderson, learning that the secessionists had made preparations to capture Fort Moultrie and seize the other fortifications near Charleston, transferred his force to Fort Sumter. Here he was able to mount only 52 of the lighter guns. About the same time commissioners were sent by the state authorities to demand from the government of the United States the surrender of all the forts in South Carolina. President Buchanan refused, and Fort Sumter was virtually in a state of siege. Early in January, 1861, an unsuccessful attempt was made to throw in supplies, by means of an expedition from New York in the steamer Star of the West. On April 11 Gen. Beauregard, who had been placed in command of the forces raised by the confederate government, and had constructed powerful batteries on every point commanding Fort Sumter, demanded the immediate surrender of the fort. Major Anderson refused, but said that if he was not reënforced by the 15th he would evacuate the fort; to which Beauregard responded that he would open fire at about half past 4 on the morning of April 12. Fire was accordingly opened, and in a few hours the works were seriously damaged. The bombardment was fiercely continued, but no one was hurt. The provisions and ammunition being nearly exhausted, the evacuation of the fort was agreed upon on the afternoon of the 13th, and on the 14th Major Anderson marched out with flying colors. The confederates strengthened the fort and put in a strong garrison, and until near the close of the war it formed the main defence of Charleston. In April, 1863, it was unsuccessfully bombarded by a monitor fleet under Admiral Du Pont. Still later it was subjected to a heavy fire from batteries erected on Morris island, and reduced almost to a mass of shapeless ruins; but every direct attempt to take it failed, and it fell into Union hands only when Charleston was finally abandoned by the confederates in February, 1865. (See CHARLESTON.) On April 14, 1865, just four years after the surrender, the Union flag, the same which had been lowered in 1861, was again formally raised over the dilapidated walls of Fort Sumter.

**SUMTER, Thomas,** an American revolutionary general, born in Virginia in 1734, died near Camden, S. C., June 1, 1832. He was a volunteer in the French and Indian war, was present at Braddock's defeat, and in March, 1776, became lieutenant colonel of the second regiment of South Carolina riflemen. After the capture of Charleston by the British in 1780, he took refuge in the swamps of the Santee, and, with the rank of brigadier general, became one of the most active and able partisan leaders of the south. On July 12 he defeated a British detachment on the Catawba, but on Aug. 18 was surprised and routed at Fishing creek by Tarleton. He collected another corps, and on Nov. 12 defeated Col. Wemyss, who had attacked his camp in Chester district near Broad river. A few days later Tarleton attempted to surprise him while encamped at Blackstocks on the Tiger river, but was compelled to retreat with severe loss. Sumter was severely wounded in this encounter; but in March, 1781, he raised three new regiments, and, in concert with Marion, Pickens, and others, harassed the enemy's scattered posts in the low country. In January, 1781, congress passed a resolution of thanks to him and his men. He was a member of congress from South Carolina in 1789–'93, and United States senator in 1801–'9; and in 1809 he was appointed minister to Brazil, where he remained two years. He was the last surviving general of the revolution.

**SUN,** the central ruling body of the planetary system, and the great source of light and heat. The visible orb of the sun, as distinguished from the complex structure of which that orb is but a part, is a globe about 853,000 m. in diameter. So far as observation extends, this globe is spherical in shape, no difference having been detected in the polar and equatorial diameters. In fact, no single set of measurements, however carefully made, could lead to the conclusion that there is any compression in the solar orb, since the equality of the diameters results not from a single set of measures, but from comparisons between many thousands of observations made at Greenwich, Paris, Washington, and other leading observa-

tories. The volume of the sun exceeds the earth's nearly 1,253,000 times. His mean density is almost exactly equal to one fourth of the earth's, so that his mass exceeds hers about 316,000 times. Gravity at the visible boundary of the solar globe exceeds gravity at the earth's surface about 27·1 times; and a body dropped from rest near the sun's surface would fall through 436 ft. in the first second, and have acquired a velocity of 872 ft. a second, or about 10 m. a minute. The sun's mass exceeds the combined mass of all the planets about 750 times. His mean distance from the earth has been estimated at about 91,430,000 m.; though we may expect that the results obtained during the late transit of Venus (December, 1874) and to be obtained during the coming transit (December, 1882) will lead to some correction of this estimate. It already appears probable that the sun's estimated mean distance must be increased to about 92,000,000 m. The greatest and least distances of the sun from the earth (assuming his mean distance to be 91,430,000 m.) are respectively 92,963,000 and 89,897,000 m.; and his apparent diameter varies from 31′ 31·8″ to 32′ 36·4″ as he passes from his greatest to his least distance.—The sun has an apparent motion among the stars from west to east along the great circle called the ecliptic (see ECLIPTIC), making a complete circuit of the heavens in 365 days, 6 hours, 9 minutes, and 9·6 seconds, though the passage from vernal equinox to vernal equinox (first point of Aries) occupies only 365d. 5h. 48m. 48·6s., because of the precession of the equinoxes. (See PRECESSION.) These two periods are called respectively the sidereal year and the tropical year. There is one other astronomical year (besides the civil, Julian, and lunar years) known as the anomalistic year, being the interval separating successive passages of the perigee of the solar path, viewed geometrically; its length amounts to 365d. 6h. 13m. 49·3s. The apparent motion of the sun is not uniform in the ecliptic, owing to the eccentricity of the earth's orbit; it is greatest about Dec. 31 to Jan. 1, when he moves through 1° 1′ 9·9″ in 24h., and least about June 30–July 1, when he only moves through 0° 57′ 11·5″ in 24h. The sun has also three real motions: 1, an axial rotation, the nature of which will presently be described; 2, a motion about the centre of gravity of the whole solar system, but in consequence of the great superiority of his mass over that of all the other bodies this centre of inertia is always within the sun's volume; 3, a progressive motion in space toward the direction of the constellation Hercules, the rate of which has been estimated at 150,000,000 m. per annum, but on evidence exceedingly questionable. The fact of solar motion toward Hercules is as nearly certain as possible, but the rate of this motion is not known. Recent researches suggest that it is far greater than the rate just mentioned, great though that rate may appear.—Examined with a telescope, the sun's surface, which appears very nearly uniform to the naked eye, is seen to be brightest near the centre, and to grow progressively darker toward the circumference. It is also marked by various irregularities, spots, faculæ, mottling, besides other appearances requiring greater telescopic power for their detection. The spots on the sun were independently discovered by Galileo, Fabricius, Scheiner, and Harriot. It was soon perceived that they move in such a way as to indicate that they are real surface markings, not bodies passing between the earth and the sun, and that therefore the sun's rotation can be measured by observing them. It was found that the sun rotates in a period of about 25⅓ days; and as the spots do not at all times pass on straight lines across the sun's face, but sometimes on a course slightly bowed upward and at others on a course slightly bowed downward, it was seen that the sun's axis of rotation is not quite upright as referred to the plane of the ecliptic, but slightly inclined. The following elements of the sun's rotation belong to the astronomy of recent times, having been deduced from results obtained by Carrington and Spörer, reduced to the year 1869:

| ELEMENTS. | Carrington. | Spörer. |
|---|---|---|
| Longitude of node of solar equator.... | 73° 57′ | 74° 87′ |
| Inclination of solar equator........... | 7 15 | 6 57 |
| Mean diurnal rotation.................. | 14 18 | 14 27 |
| Mean rotation period................... | 25·38d. | 25·234d. |

It will be perceived that a mean rotation is indicated. Carrington's observations have shown that spots in different solar latitudes travel at different rates, varying in fact from a daily rotation through about $12\frac{2}{3}°$ in lat. 50° (nearly the highest in which spots have been observed) to a daily rotation through nearly $14\frac{1}{2}°$ at the solar equator (where, however, spots are very rarely seen). Carrington gives the following formula for the rotation in different solar latitudes: daily rotation $= 14° 25' - (2° 45') \sin.^{\frac{7}{4}}$ lat.; but this formula is purely empirical. The curious point about this variation in the rate of turning is that, taking two parts of the visible solar surface in the same longitude, but one in lat. 45° (say), the other on the equator, the latter will advance further and further in longitude from the former, gaining daily about two degrees, so that in the course of about 180 days it will have gained a complete revolution. That is to say, the sun's equator makes about two revolutions more per annum than the regions in 45° north and south solar latitude. The spots on the sun have usually a dark central region called the *umbra*, within which is a still darker part, called the *nucleus*, while around this there is a fringe of fainter shade than the umbra, called the *penumbra*. Although the umbra and nucleus appear dark, however, it is not to be supposed that they are really dark; in fact, Prof. Langley of Pittsburgh has succeeded in examining the light from the nucleus alone,

and he finds that though the nucleus looks perfectly black by contrast with the general surface, it shines in reality with a light unbearably brilliant when viewed alone, while his thermal measurements show that the heat from the nucleus is even greater proportionately than the light, and not very greatly below the heat of the surrounding surface. The boundary between the umbra and the penumbra is in general well defined; and commonly the inner part of the penumbra nearest to the umbra is brighter than the exterior portion. Many spots are of enormous size, so as to be visible with the naked eye. Sir W. Herschel saw one in 1779 which had a diameter exceeding 50,000 m., and many far larger than this have since been seen. The spots are not scattered over the whole surface of the sun, but are for the most part confined to two belts between lat. 5° and 30° on either side of the solar equator. An equatorial zone 6° wide is almost entirely free from spots. Owing to this peculiarity of arrangement, Sir J. Herschel suggested the existence of motions in the solar atmosphere corresponding to our trade winds; but the circumstances of the solar orb and atmosphere differ so entirely from those of our earth and air, that such comparisons are unsafe. Dr. Wilson of Glasgow was the first to show that the umbra of a spot is below the level of the penumbra. He observed that a spot, visible in 1769, changed in shape as it traversed the solar disk, precisely as it would if the spot had been a depression below the general surface of the sun. The penumbra was markedly wider on the side nearest the edge of the solar disk than on the other side, whereas the reverse should have been the case if the spot had been a surface marking. Sir W. Herschel in 1777 began a series of solar observations which before long confirmed Wilson's views. He was led to explain the spots by the theory that the sun's globe is surrounded by two layers of clouds, suspended in an atmosphere at different elevations. He supposed the upper cloud stratum to be self-luminous, and to be the source of the solar light, or the true photosphere (to use a convenient term invented by Schröter). The lower layer he regarded as opaque, and as owing whatever light it appears to possess to the reflection of light received from the upper layer. He supposed that when an opening is formed in the outer layer we see merely a penumbral spot; but that when the inner layer also is displaced we see the true surface of the sun, which he supposed to be solid, and not necessarily so heated as to be unfit for habitation. Modern researches show this part at least of Herschel's theory to be wholly untenable, everything tending to prove that the whole mass of the sun to its innermost core is intensely heated. The recognition of a nucleus within the umbra would seem to indicate that a third cloud layer exists within the second or internal layer of Herschel's theory. But the observations of Prof. Langley show that most probably all the features of the solar photosphere yet observed are phenomena of cloud envelopes, since he has been able to recognize cloud forms at one level floating over cloud forms at a lower level, while even in the (relatively) darkest depths of the nucleus clouds are still to be perceived, though so deep down that their outlines can be barely discerned. The study of the solar spectrum (see SPECTRUM ANALYSIS), while revealing much respecting the constitution and physical condition of the solar orb, has thrown some light also on the nature of sun spots. Mr. Huggins, for instance, has found that several of the absorption bands belonging to the solar spectrum are wider in the spectrum of a spot, a circumstance indicative of increased absorption so far as the vapors corresponding to such lines are concerned. Spots are more numerous in some years than in others, and occasionally no spots are visible for many successive days. Schwabe of Dessau began to study this peculiarity in 1826, and after many years recognized a remarkable periodicity in the frequency of sun spots. They are found gradually to increase in number during a certain period, and then to decrease until at length there are no spots; then they increase again, and so on. According to Schwabe's earlier investigations, the cycle lasts 10⅓ years; but Wolf of Zürich has found by examining earlier observations that the true average period is about 11·11 years. (See MAGNETISM, TERRESTRIAL.) Various minor cycles have been suspected, besides a long cycle of about 56 years. Wolf in 1859 presented a formula by which the frequency of spots is connected with the motions of the four bodies, Venus, the earth, Jupiter, and Saturn. Prof. Loomis of Yale college has since advocated a theory (suggested by the present writer in 1865, in "Saturn and its System," p. 168, note) that the long cycle of 56 years is related to the successive conjunctions of Saturn and Jupiter. But the association is as yet very far from being demonstrated, to say the least.—Besides the spots, the telescope reveals minute dark dots or pores mottling the surface, which have been lately found to be the intervals separating numberless cloud-like forms, apparently minute, but in reality from 200 to 1,000 m. in diameter, the brilliancy of which so greatly exceeds that of the intervening spaces that they must be recognized as the principal radiators of the solar light and heat. These are found to be in constant fluctuation, and Sir J. Herschel compares their appearance to the slow subsidence of some flocculent chemical precipitates in a transparent fluid when viewed perpendicularly from above. Near the great spots or groups of spots there are often seen streaks more luminous than the neighboring surface, called *faculæ*. They are oftenest seen toward the borders of the disk. Mr. Dawes saw, on Oct. 22, 1859, in a large mass of faculæ, one bright streak forming the

very edge of the sun, and projecting irregularly beyond the circular contour, reminding him of a ridge of low hills often seen at the enlightened limb of the moon. M. Chacornac, a most diligent French investigator, observed on one occasion a sudden transformation of the luminous part of the photosphere into dark parts; luminous bridges were seen crossing the spots, and then gradually becoming dark. As these luminous bridges darkened, they at the same time plunged into the deeper parts, and became covered with other luminous bridges which formed above them.—The phenomena witnessed during total solar eclipses are next to be considered. The red prominences were first seen during the solar eclipse of July 8, 1842. In the eclipse of July 28, 1851, it was shown that they belong to the sun, since the advancing moon visibly concealed those on one side and disclosed those on the other side. During the eclipse of June 18, 1860, Secchi and De la Rue photographed the prominences at two stations in Spain, and thenceforth the solar nature of these appendages was admitted by all. As some of them were seen to extend fully 3′ from the edge of the sun on that occasion, it became manifest that they are objects of enormous dimensions, since 3′ at the sun's distance corresponds to an extension of about 80,000 m. In the Indian eclipse of August, 1868, the prominences were examined with the spectroscope by Col. Tennant, Capt. Herschel, and Messrs. Janssen and Rayet. The spectrum was found to consist of bright lines, showing that the colored prominences are masses of glowing gas, the bright lines of hydrogen were recognized, and an orange-yellow line was ascribed (mistakenly, however) to sodium. But on the following day Janssen applied a new method of research, the principle of which had been indicated earlier by Huggins ("Report of Council of Astronomical Society," "Monthly Notices," February, 1868). Since prismatic dispersion reduces the brightness of the solar spectrum, but only throws the lines of a gaseous spectrum further apart, it follows that by directing a tele-spectroscope toward the place of a prominence, the light from the air which usually obliterates the prominence light can be so reduced by sufficient dispersion that the prominence lines may be rendered visible. Janssen found this to be the case, and by noting the indications thus afforded he was able to determine the presence and even the shape of prominences at various parts of the sun's edge. Two months later, but before the news of Janssen's success had reached England, Mr. Lockyer obtained a similar result. Before long Huggins, who had been the first to enunciate the principle of the method, showed how by opening the slit of the spectroscope the whole of a prominence could be seen at once. Since then the prominences have been successfully studied by Zöllner, Respighi, Secchi, and others. Prof. Young of Dartmouth college has been particularly successful in applying this method of research.—Even before the prominences were discovered, it was known that a border of red light surrounds the solar disk; it had been seen on the eastern side at the beginning of total eclipse, and on the western side at the end. In 1860 this envelope was very clearly seen, and even photographed. It has been designated as the sierra, because of its serrated appearance; but recently the name chromosphere (for chromatosphere) has been given to it. The observations of prominences and sierra as summarized by Secchi indicate the following results: "The sierra presents four aspects: 1, smooth, with defined outline; 2, smooth, but no defined outline; 3, fringed with filaments; and 4, irregularly fringed with small flames. The prominences may be divided into three orders, heaps, jets, and plumes. The heaped prominences need no special description. The jets are those to which alone the following description by Respighi (erroneously given as generally applicable to all prominences) can be applied: 'They originate generally in rectilinear jets either vertical or oblique, very bright and very well defined. They rise to a great height, often to a height of at least 80,000 m., and occasionally to more than twice that; then bending back, fall again upon the sun like the jets of our fountains. Then they spread into figures resembling gigantic trees more or less rich in branches.' Their luminosity," proceeds Secchi, "is intense, insomuch that they can be seen through the light clouds into which the sierra breaks up. Their spectrum indicates the presence of many elements besides hydrogen. When they have reached a certain height they cease to grow, and become transformed into exceedingly bright masses, which eventually separate into fleecy clouds. The jet prominences last but a short time, rarely an hour, frequently but a few minutes, and they are only to be seen in the neighborhood of the spots. Wherever there are jet prominences there also are faculæ. The plume prominences are distinguished from the jets in not being characterized by any signs of an eruptive origin. They often extend to an enormous height; they last longer than the jets, though subject to rapid changes of figure; and lastly they are distributed indifferently over the sun's surface. It would seem that in jets a part of the photosphere is lifted up, whereas in the case of plumes only the sierra is disturbed." (It is here of importance to remark that these eruptive prominences, particularly associated with spots, are of late becoming recognized as chiefly due to metallic vapors, in distinction from the "plume" forms, which are largely composed of hydrogen.) This account would be incomplete without a description of the remarkable solar explosion actually witnessed by Prof. Young on Sept. 7, 1871. Fig. 1 represents a cloud prominence he had been observing on the eastern limb of the sun. It was about 100,000 m. long by 54,000 m. high. He was called

away at 12h. 30m., and on returning at 12h. 55m. "found that the whole thing had been lit-

Fig. 1.—Prominence as it appeared at half-past 12 o'clock, Sept. 7, 1871.

erally blown to shreds by some inconceivable up-rush from beneath." Fig. 2 represents the appearance when the up-rushing hydrogen had attained its greatest height, exceeding 200,000 m. "The whole phenomenon," he says, "suggested most forcibly the idea of an explosion under the great prominence, acting mainly upward, but also in all directions outward, and then after an interval followed by a corresponding in-rush." A strange circumstance remains to be mentioned: "The same afternoon a portion of the sierra on the

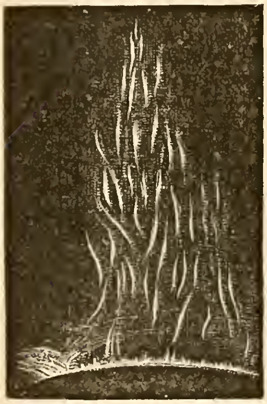

Fig. 2.—As the above appeared half an hour later.

opposite limb of the sun was for several hours in a state of unusual brilliance and excitement, and showed in the spectroscope more than 120 bright lines whose position was determined and catalogued—all that I had ever seen before and some 15 or 20 besides." Before passing from the prominences it may be well to indicate the laws of their numerical distribution, as determined by Secchi and others. This is shown in fig. 3. On the left side the results of Carrington's observation of 1,414 spots between 1853 and 1861 are indicated, and on the right the result of Secchi's observations of 2,767 protuberances in 1871, the number of spots or prominences being of course shown by the length of the radial lines. The dotted line on the right-hand side represents in the same manner the distribution of the larger prominences, viz., those exceeding 1′ or 27,000 m. in height.—During a total eclipse there appears around the black body of the moon a halo or glory of light, bright, close to the place of the concealed sun, but gradually fading away outward, until its light is lost in the general tint of the sky. In this glory of light, which is called the solar *corona*, radiations are also sometimes seen, and under favorable atmospheric conditions complicated series of streaks can be seen extending to a considerable distance outward from the prominence region. Various theories were advanced in former times to explain the corona. According to one theory, it is a phenomenon caused by the solar light falling on our own atmosphere; another theory ascribed it to a lunar atmosphere. In the opinion of Leverrier and Foucault (among others), the corona is an example of the interference of light (see Light), the phenomenon being analogous to the colored fringes seen on a screen in a darkened room when a solar beam is admitted through a chink. To this theory Airy raised the objection that if, in order to make the analogy perfect, the eye is placed in the position of the screen, no colored fringes are seen. It is shown that the corona is partly polarized, and hence partly consists of reflected light. It has been further proved that the plane of polarization passes through the sun and the observer. This was regarded by Airy as pointing to the existence of an atmospheric medium capable of reflecting light, and extending from the earth to the moon. But in more recent times astronomers began to perceive that no other theory can be admitted than that which regards the corona as a true solar appendage. (Of course, it must be admitted that a portion of the light around the eclipsed sun comes from our own atmosphere, which must necessarily be illuminated by the true corona

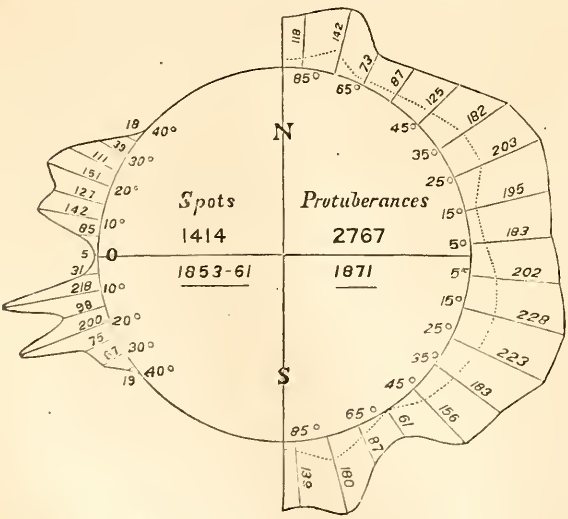

Fig. 3.—Relative Frequency of Protuberances and Sun Spots.

during eclipse, precisely as it is illuminated by the sun when there is no eclipse; but it will readily be understood that this portion of reflected light is very small in amount.) During the solar eclipse of August, 1869, Profs. Young and Harkness discovered that certainly one bright line exists in the spectrum of the corona, and two other lines were suspected. European astronomers expressed doubt as to the accuracy of this observation; but it was confirmed during the Mediterranean eclipse of December, 1870, when Young thus summed up his own and other observations: "There is surrounding the sun, beyond any further reasonable doubt, a mass of self-luminous gaseous matter, whose spectrum is characterized by the green line 1,474 Kirchhoff. The precise extent of this it is hardly possible to consider as determined, but it must be many times the thickness of the red hydrogen portion of the sierra, perhaps on an average 8′ or 10′, with occasional horns of twice that height. It is not at all unlikely that it may even turn out to have no upper limit, but to extend from the sun indefinitely into space." During the same eclipse, Brothers of Manchester and Willard of Philadelphia (the latter acting under the directions of Prof. Winlock of the Harvard observatory) photographed the corona successfully from two distant stations, Willard being near Jerez in Spain, Brothers near Syracuse in Sicily. The views thus obtained agreed so closely (save in circumstances depending on photographic conditions) as to leave no doubt that the corona is a solar phenomenon. Doubts were still expressed, and it was not until the solar eclipse of December, 1871, that these were finally removed. On that occasion the spectroscopic and photographic results were alike decisive. Janssen with the spectroscope not only recognized the bright lines before seen and others less bright, but also a faint solar spectrum, which, since our atmosphere during total eclipse is certainly not illuminated by sunlight, must have been reflected by matter in the solar corona, such as vaporous clouds, meteor flights, or the like. Mr. Davis, a photographer sent out at Lord Lindsay's expense, obtained five excellent photographs of the corona, all agreeing perfectly *inter se*, excepting in extent. This proved certainly that the features of the corona do not change as they would if the phenomenon depended on the passage of light rays athwart lunar inequalities, to fall upon scattered matter at a less distance than the moon. Again Col. Tennant obtained six photographs, similarly accordant *inter se*, and also agreeing perfectly with Mr. Davis's at Dodabetta, a station far removed from Davis's, Baicull. Since, also, Dodabetta is near the highest peak of the Neilgherries, about 9,000 ft. above the sea level, while Baicull is close to the seashore, it will be manifest that if the features of the corona depended on the illumination of our own atmosphere, the pictures of Tennant's series would have differed altogether from those of Davis's series. Thus, independently of the spectroscopic evidence, the photographs proved that the corona is a solar appendage, at least as far as those features shown in the two series extend. But they extend from the sun in places to a distance exceeding his own diameter, and amounting in fact to more than a million miles. There is reason to believe that the true solar corona extends much further, and that in reality the zodiacal light (see Zodiacal Light) forms the outer part of the solar corona; so that if the light of the sun could be for a time obliterated without rendering his appendages invisible, we should see the corona merging gradually into the faint glow of the zodiacal light. Mr. Arthur W. Wright of Yale college has succeeded in showing that this light is not emitted from incandescent gas, but reflected from particles or small bodies, and hence derived from the sun.—Another important discovery made during total solar eclipses relates to a solar atmosphere underlying even the sierra. Secchi had observed in 1869 that close to the sun's limb the solar spectrum becomes continuous; this he considered to be due to the existence of a relatively very shallow atmosphere, consisting of the vapors which cause the dark lines of the solar spectrum. For if the brightness of the lines of these vapors corresponds very closely to the brightness of the ordinary solar spectrum for the parts near to the sun's edge, the dark lines of the latter spectrum would be cancelled, and so a continuous spectrum would be produced. For another reason, the present writer had adopted the theory that the atmosphere producing the absorption lines of the solar spectrum must be shallow, compared at least with the dimensions of the sun's globe; for he showed that a shallow and not a deep atmosphere is to be inferred from the darkening of the solar disk near its edge. The opinion thus advanced on theoretical grounds was shown to be correct by the observations of Prof. Young during the total eclipse of December, 1870; for, "directing his analyzing spectroscope to the part of the sun's limb which was to disappear last, he found that at the instant when totality commenced the solar spectrum was suddenly replaced by a spectrum consisting of a thousand soft bright lines." In other words, the vapors which by their absorptive action produce the dark lines of the ordinary solar spectrum were for the moment shining with their own light, and thus produced a spectrum of bright lines. This spectrum continued visible for a few seconds only, showing that the complex atmosphere producing it cannot be more than two or three hundred miles in depth. The observation was successfully renewed during the eclipse of December, 1871, and again during the annular eclipse of June, 1872.—How to account for the supply of the prodigious amount of heat constantly radiated from the solar surface has offered a boundless field of hypothesis. One conjecture

has been that the sun is now giving off the heat imparted to it at its creation, and that it is gradually cooling down; another ascribed it to combustion, and a third to currents of electricity. Newton and Buffon conjectured that comets might be the aliment of the sun, and of late years a somewhat similar theory (first broached by Mr. Waterston in 1853) has been in vogue, viz., that a stream of meteoric matter constantly pouring into the sun from the regions of space supplies its heat, by the conversion into it of the arrested motion. As the sun may indeed derive a small amount of heat from this cause, it deserves more attention than previous conjectures. But conjecture and hypothesis may be said to have given place to views which claim a higher title, as it is now becoming generally recognized, in accordance with modern physical theories of heat, that in the gravitation of the sun's mass toward its centre, and in its consequent condensation, sufficient heat must be evolved to supply the present radiation, enormous as this undoubtedly is. It appears to be susceptible of full demonstration that a contraction of the sun's volume of a given definite amount, which is yet so slight as to be invisible to the most powerful telescope, is competent to furnish a heat supply equal to all that can have been emitted during historical periods. According to this theory then (which is due largely to the development by Helmholtz of Mayer's great generalization), the sun's mass remains unaltered, and its temperature nearly constant, while its size is slowly diminishing as it contracts; so slowly, however, that the supply may be reckoned on through periods almost infinite as measured by the known past of our race, and which are in any case to be counted by millions of years. It would appear from early measurements of Secchi that the different portions of the solar disk do not radiate heat in uniform degrees, and his tables show that the equatorial regions are slightly hotter than the polar. It has been explained that the rapid decrease of brightness toward the edge of the sun obliges us to admit the existence of a shallow atmosphere around it. Prof. Langley has recently published tables from more extended measurements, showing the rate of absorption both of heat and light, the latter being greater than the former. As he does not now find the difference between the equatorial and polar heat observed by Secchi in 1852, the latter concludes from a comparison of his own observations with Langley's, that great changes occur in the distribution of the heat on the sun's surface. Prof. Langley has further shown that this atmosphere absorbs one half of the sun's total radiation, and he considers that its function in the solar emission is of great importance to us. A slight alteration in the thickness of this obscuring envelope would induce changes on the earth greater than those known to have occurred in its climate in past geologic epochs, which may themselves not impossibly have been due to this hitherto unrecognized cause. M. Fizeau has found that the chemical rays are similarly reduced in amount toward the edge of the solar disk, a fact which is also abundantly shown by the darkening near the edge of photographic sun pictures, like those by Rutherfurd and De la Rue.—To sum up briefly the received hypotheses of the physical constitution of the sun: Of its internal structure we know nothing, but we can infer from the low density of the solar globe as a whole that no considerable portion is solid or liquid. The regions we examine appear to consist of cloud layers at several levels floating in a complex atmosphere, in which probably most of the elements are known to us, and certainly many of them exist in the form of vapor. Outside this complex atmosphere extend envelopes of simpler constitution, though into them occasionally arise the vapors which ordinarily lie lower down. The sierra, for instance, consists in the main of glowing hydrogen gas, and that gas, whatever it may be, which produces the line near the orange-yellow sodium lines. The prominence region may be regarded as simply the extension of the sierra. The inner corona is still simpler than the sierra so far as its gaseous constitution is concerned; but here meteoric and cometic matter appears, extending to the outer corona and to great distances beyond even the visible limits of the zodiacal. Returning to the photosphere, we find it subject to continual fluctuations, both from local causes of agitation and from the subjacent vapor acting by its elasticity to burst through it; the faculæ, which are found to be above the general level of the photosphere, are taken to be heapings up of the luminous matter like the crested surges of the sea. All the strata are subject to great movements, which sometimes have the character of uniform progression analogous to our trade winds, and sometimes are violent and resemble in their effects our tornadoes and whirlwinds. Eruptive action appears to operate from time to time with exceeding violence, but whether the enormous velocities of outrush are due to true explosive action (which would compel us to believe that the sun is enclosed by a liquid shell, so as to resemble a gigantic bubble), or to the uprising of lighter vapors from enormous depths, as heated currents rise in our own atmosphere, is not as yet certainly known. (See p. 901.)

**SUN BIRD**, the name commonly given to the *promeropidæ*, a family of tenuirostral birds, with a long, slender, and usually curved bill, the nostrils placed at the base and covered with a scale, wings of moderate size, and short tarsi covered with broad scales. They inhabit the tropical regions of both hemispheres; the subfamily *promeropinæ*, including by far the most species, is confined to the old world, and the *cœrebinæ* to the new. The true sun birds belong to the former, and have a long, slender, curled, and sharp bill, sometimes finely serrated on the margins; the tail is long, the central

feathers often exceeding the rest. They are found in the islands of the Pacific and Indian oceans, and on the continents of Africa and Asia; they are the humming birds of the old

Fiery-tailed Sun Bird (Nectarinia ignicauda).

world, having similar habits and the same brilliant colors, but are larger. The genus *nectarinia* (Illig.) contains more than 100 species, mostly African. The nest, of an elegant form, is usually suspended from the end of a twig, with an opening at the side; the eggs are two to four. The *cœrebinæ* or guitguits have a shorter, broader, and nearly straight bill, and long pointed wings; they are found in tropical South America and the West Indies; the plumage is very beautiful. The nest is protected by a long funnel or by two compartments against insects, birds, serpents, and lizards.

**SUNBURY,** a borough and the capital of Northumberland co., Pennsylvania, on the E. bank of the Susquehanna river, 42 m. N. of Harrisburg, and 114 m. N. W. of Philadelphia; pop. in 1870, 3,131. It has a daily and three weekly newspapers, and several manufactories and machine shops. It is connected by rail with Philadelphia and the Shamokin mining region, and about 200,000 tons of coal are shipped annually.

**SUNBURY,** a S. central county of New Brunswick, Canada, intersected by the St. John river; area, 1,203 sq. m.; pop. in 1871, 6,824, of whom 2,839 were of English, 2,655 of Irish, and 552 of Scotch origin or descent. The surface is nearly level; the soil is fertile and heavily wooded. The European and North American railway and Fredericton branch traverse the county. Capital, Oromocto.

**SUNDA ISLANDS,** a former designation of those islands of the Indian archipelago which surround the Java sea. They were divided into the greater and the lesser Sunda islands, the former including Sumatra, Borneo, Celebes, and Java, and the latter the chain of islands which extends from the E. extremity of Java to Papua, exclusive of the Moluccas.

**SUNDA STRAIT,** an arm of the sea between the islands of Sumatra and Java, which leads from the Indian ocean to the Java sea. The length of the channel upon the Sumatra side, from Flat point, in lat. 5° 59′ S., to Hog point, is about 85 m.; and upon the opposite coast, from Java head, lat. 7° 5′ S., to Bantam point, about 100 m. The breadth of the strait where it joins the Indian ocean is about 70 m., and at the end next the Java sea about 20 m.

**SUNDAY** (Sax. *Sunnan dæg*), the first day of the week, identical with the Roman *dies Solis* (day of the sun). The keeping of this as a sacred day, in memory of Christ's resurrection and of the descent of the Holy Ghost, dates from the beginning of Christianity. It is probable that the first Jewish Christians kept this day holy, while conforming also to their legal sabbath. It was called the Lord's day in all the churches; but it was also popularly designated as Sunday as soon as the gentile element began to prevail. According to De' Rossi, the first monumental inscription calling it the Lord's day is of the year 403. Its first official recognition is in an edict of Constantine in 321, ordering that all work should cease in the cities "on the venerable Sunday," but permitting necessary husbandry to be attended to. The Theodosian code prescribed that "on the Sunday, rightfully designated by our ancestors as the Lord's day, all lawsuits and public business shall cease." (See LORD'S DAY.)

**SUNDAY SCHOOLS.** The earliest recorded Sunday schools were the schools of catechumens, organized, according to Tertullian, in A. D. 180, though less formal instruction of Christian children and novitiates prevailed earlier. The schools of the catechumens flourished till the 6th century. In 1527 Luther established Sunday schools in Wittenberg for the instruction of children who could not attend the day schools. In 1560 Knox inaugurated them in Scotland. In 1580 Archbishop Borromeo of Milan established a system of Sunday schools throughout his diocese, and about the same time there were similar schools in France and the Netherlands. In the 17th century the clergy statedly catechised the children in some parishes of England; and Joseph Alleine, author of the "Alarm," opened a Sunday school in 1668. There was a Sunday school in Roxbury, Mass., in 1674, and one in Plymouth, Mass., in 1680. About 1740 Ludwig Häcker established a school in Ephratah, Lancaster co., Pa., which continued until the building was taken for a hospital during the revolution. Modern Sunday schools, however, were originated by Robert Raikes, who in 1781 gathered poor children from the streets in Gloucester, England, and employed female teachers at a shilling a day for their instruction. The children were taught from 10 A. M. to 12; then, after an hour's recess, read a lesson and went to church. After church they repeated the catechism till after 5, and were then charged to go home at once and quietly. Raikes published an account of his work in the "Gloucester Journal" in 1783, which was republished in the "Gentleman's Magazine," and schools upon his plan were soon estab-

lished in the principal towns of England. Scotland had similar schools as early as 1782, and they were established in Ireland in 1785. The London Sunday school society was organized in 1785, and in 16 years it spent £4,000. In 1786 it was thought that there were 250,000 children in Sunday schools in Great Britain. Bishop Asbury established one in Hanover co., Va., in 1786, and Bishop White one in Philadelphia in 1791. In 1790 the Methodist Episcopal conference at Charleston, S. C., resolved to establish schools for whites and blacks. Katy Ferguson, a poor negro woman, is said to have established one in New York in 1793. Samuel Slater opened a Sunday school for his operatives in Pawtucket, R. I., in 1797; and Mrs. Isabella Graham and her daughter, Mrs. Divie Bethune, who had seen the English schools, opened one in a private house in New York in 1801. The important change from paid to volunteer teachers is said to have been adopted by the Methodists at Bolton, England, about 1786. The "Gratis Sunday School Society" was established in Scotland in 1797, and voluntary teaching was general in England in 1800. In 1803 the London Sunday school union was formed, to foster voluntary teaching. Soon the churches began to assume charge of Sunday schools, in the United States about 1809; and the instruction then became more exclusively religious. Schools were opened in the Protestant churches of all denominations in Great Britain and the United States, later among the Roman Catholics, and more recently among the Quakers. Since 1848 special attention has been given to mission schools for the vagrant children of large cities. In 1875 there were 140 Protestant mission schools in New York. As now organized, a Sunday school has a superintendent with various assistants and a number of teachers, each of whom has a class of scholars. The classes are of different grades, but generally study the same Scripture lesson, their study being separate, but all the classes uniting in worship. The session generally continues an hour or an hour and a half. Schools upon this plan have been introduced by English and American missionaries in all lands; but the system has been adopted in the national churches of continental Europe only within the last 20 years. The following table gives the fullest statistics accessible for 1874:

| COUNTRIES. | Begun in | Schools. | Teachers. | Scholars. |
|---|---|---|---|---|
| France | 1854 | 990 | ...... | 41,520 |
| Belgium | 1856 | 34 | 95 | 1,120 |
| Norway and Sweden | 1859 | ...... | ...... | ....... |
| Germany | 1863 | 1,218 | 4,643 | 81,785 |
| Netherlands | 1863 | 520 | 2,111 | 58,000 |
| Italy | 1863 | 58 | 110 | 8,186 |
| Cisleithan Austria | 1872 | 6 | 30 | 300 |
| Hungary | 1872 | 6 | 30 | 350 |
| Switzerland | .... | 600 | 2,096 | 46,370 |
| Spain | .... | 20 | 95 | 1,000 |
| Greece | .... | 8 | 18 | 339 |
| Great Britain and Ireland (estimated) | .... | ...... | 310,000 | 3,050,000 |
| Canada | .... | 4,401 | 35,745 | 271,881 |
| United States | .... | 69,871 | 753,060 | 5,790,683 |

Among the most important societies formed for the promotion of Sunday schools are the following:

| SOCIETIES. | Begun in | Expended for missionary work in 1874. |
|---|---|---|
| London Sunday school union | 1803 | £4,059 |
| American Sunday school union | 1824 | $90,079 |
| Methodist Episcopal Sunday school union | 1827 | $15,781 |

These societies also publish hymn books, books and papers explaining the Bible lessons, and books for the lending libraries, with which most schools are furnished. Sunday school publications are now issued by regular business houses, as well as by church boards and tract societies. (See Tract and Publication Societies.) Conventions of Sunday school teachers have been held in the United States since 1832. A world's convention met in London in 1862. A German national convention was held in Hamburg in 1874. In 1875 there were in the United States 21 state conventions, and a national and international convention. Since 1866 a uniform series of Bible lessons has been widely used in the United States, and since 1872 has been adopted in Europe and in the missionary schools of Asia and Africa. Comments on these uniform lessons have been prepared by distinguished clergymen, translated into many languages, and issued in pamphlets and papers for teachers, and in "lesson leaves" for scholars, in many millions of copies.

**SUNDERBUNDS**, a marshy tract of British India, in Bengal, stretching across the lower part of the delta of the Ganges, between the bay of Bengal and the inhabited parts of the delta, from the river Hoogly to the island of Rabnabad, 158 m., with a breadth of about 75 m.; area, over 7,000 sq. m.; pop. very small. The soil is alluvial, and the whole district is cut up into innumerable wooded islands by rivers and creeks, many of them navigable for vessels of considerable size. The woods swarm with tigers, the waters with crocodiles, and other tropical animals abound. Salt is manufactured from the sea water to a sufficient extent to supply the demand of the lower provinces of Bengal. The Sunderbunds are included within the district of the 24 Pergunnahs.

**SUNDERLAND**, a town and parliamentary borough of Durham, England, at the mouth of the river Wear in the North sea, 12 m. N. E. of the city of Durham and 240 m. N. by W. of London; pop. of the town in 1871, 98,335. The Wear passes through the borough, and is crossed by an iron bridge, high enough for large sailing vessels to pass, which connects Monk Wearmouth with the S. side of the river. The harbor is formed by the mouth of the river, and is protected by piers. The docks on the S. side of the river have an independent entrance to the sea. Ship building amounts in seasons of ordinary prosperity to more than

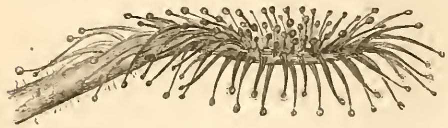
70,000 tons. The entrances in 1873 were 8,091 British vessels, tonnage 1,705,925, and 1,257 foreign vessels, tonnage 268,511; clearances, 8,140 British vessels, tonnage 1,828,094, and 1,299 foreign vessels, tonnage 296,602. The value of exports was £1,615,190. The chief manufactures consist of earthenware and glass, and all kinds of articles required for fitting out vessels. Window glass and glass bottles are very largely manufactured.

**SUNDERLAND. I. Robert Spencer,** second earl of, an English statesman, born in Paris about 1641, died at Althorp, Sept. 28, 1702. After serving as ambassador to Spain and France, he became in 1679 secretary of state. In 1681 he went out of office, but was recalled in 1682, and exercised a controlling influence during the remainder of the reign of Charles II. Under James II. he remained secretary, and was also made president of the council. In 1687 he became a Roman Catholic; but he carried on a secret intrigue with the prince of Orange, and in October, 1688, was dismissed by James. On the arrival of the prince of Orange, Sunderland went to Rotterdam, where he was thrown into prison, but was released by order of William. He then went to Amsterdam, turned Protestant again, and after residing about two years at Utrecht returned to England, although excepted in the act of indemnity. On April 19, 1697, William appointed him lord chamberlain and one of the lords justices; but on Dec. 25 he resigned. **II. Charles Spencer,** third earl of, an English minister, son of the preceding, born in 1674, died April 19, 1722. Professing republican principles, he entered the house of commons in 1695 as member for Tiverton, and continued in the next three parliaments. In 1705 he was sent to Vienna as envoy extraordinary and plenipotentiary, and in 1707 became secretary of state, but was dismissed in 1710. He was generally regarded as the head of the whig party, and on the accession of George I. he was made lord lieutenant of Ireland, in 1715 lord privy seal, and in April, 1717, secretary of state. The house of commons implicated him in the criminal transactions of the South sea scheme; but he was acquitted by a vote of 233 to 172, though with loss of his office. He spent his remaining days in intrigues to effect the downfall of Walpole. By his marriage with the second daughter of the great duke he became progenitor of the present house of Marlborough, their son succeeding as second duke.

**SUNDEW,** the common name of plants of the genus *drosera* (Gr. δροσερός, dewy), which gives its name to the *droseraceæ*, a small order of remarkable plants, one of which, the Venus's fly-trap, is described under Dionæa. There are about 100 species of *drosera*, distributed all over the world, except in some of the Pacific islands; they are perennials, and either stemless, with a rosette of leaves rising from the rhizome, or have stems with alternate leaves; with a few rare exceptions, the leaves bear numerous bristles or hairs, each of which exudes a drop of clear glutinous fluid; this exudation of the hairs, which glistens like dew drops, is recognized in the common and botanical names. Six species are found within the limits of the United States; they are all stemless, with the leaves circinate in the bud (*i. e.*, rolled up from the apex downward), all in a tuft at the base, from the centre of which rises a naked scape bearing the flowers at the top in a one-sided raceme, the undeveloped apex of which droops, leaving the open flower apparently the highest. The white or rose-colored flowers, which open only in sunshine, have in our species their parts mostly in fives, the calyx and corolla withering and remaining in fruit; the globular ovary has three or five styles, so deeply cleft as to appear like six or ten, and ripening into a one-celled, three-valved capsule containing numerous seeds, with a pitted surface. All are found in bogs or wet sands, some very rare and others widely distributed. The most common is the round-leaved sundew (*D. rotundifolia*), which extends from Canada to Florida; its leaves, 1 to 2 in. long, and spreading upon the ground, have an orbicular blade narrowing abruptly into a petiole; the scapes, 6 in. or more high, bear white flowers with their parts sometimes in sixes. The long-leaved (*D. longifolia*), less frequent, but with a similar range, often grows in the water, when its caudex is several inches long; the leaves, more or less erect, have an oblong blade which tapers gradually into the petiole, and are from 1½ to 4 in. long; scape and flowers similar to the preceding. Both of these species are also natives of Europe, the first named extending from northern Spain to the arctic regions and throughout Russian Asia. The short-leaved (*D. brevifolia*) has wedge-shaped leaves only ½ in. long, and white flowers on a scape 3 in. or more high; this and *D. capillaris*, formerly regarded as a long-leaved variety of it, are found only from Florida to North Carolina. The slender sundew (*D. linearis*) is our most local species, being found along Lake Superior and in a few other localities further west; its narrowly linear leaves are 4 to 6 in. long, the blade barely ⅛ in. wide; the scape, at first shorter than the leaves, but at length longer, has white flowers. The thread-leaved sundew (*D. filifolia*) occurs

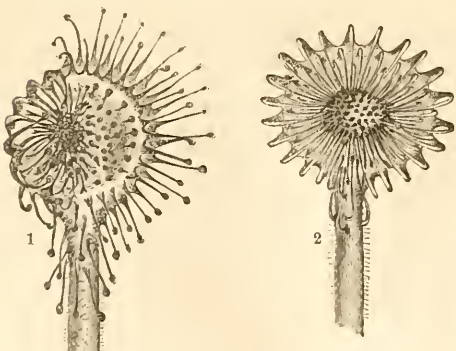
Round-leaved Sundew (Drosera rotundifolia).

in wet sand along the coast, from Plymouth, Mass., to Florida; it has a bulb-like base or corm, from which rise the singular thread-like leaves, from 6 to 12, and sometimes 18 in. long, in which there is no distinction between blade and petiole, having the upper surface



Leaf of Round-leaved Sundew, viewed laterally. (Magnified four times.)

somewhat convex; the scapes, which are a little longer than the leaves, bear handsome rose-purple flowers more than half an inch across. —It was long known in a general way that numerous small insects were caught by coming in contact with these viscid glands, and about 1860 it was discovered that this was not accidental, but that the leaves were especially adapted to the work, and that though their motions are much slower than those of the related *dionæa*, they are none the less effective, and the droseras now rank among the plants which catch and digest insects for their own nourishment. Darwin, in his recent work on "Insectivorous Plants" (1875), gives in great detail the investigations of himself and others upon droseras and a few other genera, but two thirds of the work is devoted to *drosera rotundifolia* alone. The upper surface of the leaf is thickly studded with the glandular hairs already mentioned, to which Darwin gives the name of tentacles; the average number of these on 31 leaves was found to be 192; those on the central part of the leaf are short and erect, with green pedicels; toward



Round-leaved Sundew, seen from above. 1. Tentacles partly inflected. 2. Tentacles entirely inflected.

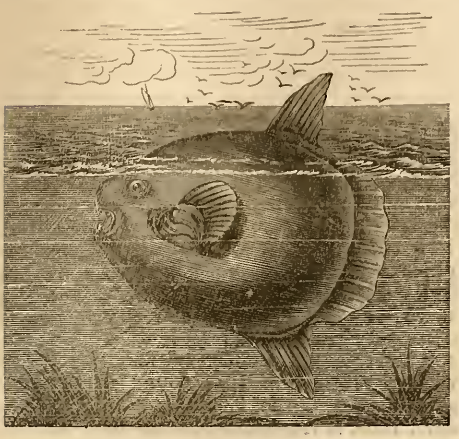
the margin they are larger, inclined outward, and have purple pedicels; those upon the extreme margin project on the same plane with the leaf, and are commonly reflexed, while a few which spring from the top of the petiole are the largest of all, some being ¼ in. long; each tentacle consists of a straight, hair-like pedicel or stalk, consisting of several rows of elongated cells filled with a purple fluid; the gland at the apex is mostly oval and complex, and secretes a colorless and extremely viscid matter, which may be drawn out into long threads. If a small object, organic or inorganic, be placed on the centre of the leaf, the tentacles nearest it begin to bend toward it; this impulse is transmitted to those further off, until all, including the marginal ones, are closely inflected over the object, a process requiring from one to four or five hours. In case an insect alights upon or touches one of these glands, it is held by the secretion, and in its struggles comes in contact with other glands, which hold it until the tentacles can fold over it one by one and completely imprison it. The insects thus caught are actually digested, and the nutritive material absorbed to contribute to the growth of the plant; it is found that the secretion from these glands or

Thread-leaved Sundew (Drosera filiformis).

tentacles has a digestive power closely resembling that of the gastric juice of animals, acting even upon cartilage and the fibrous substance of bone. Experiments with several other species of *drosera* show that, though the leaves vary greatly in shape and appearance from those of *D. rotundifolia*, they differ but little in their functions. Some of the curious results obtained by Mrs. Treat with our thread-leaved sundew are given in the article Insectivorous Plants.

**SUN FISH,** the common name of the fishes of the diodon family and genus *orthagoriscus* (Schn.). The skeleton is soft and only partially ossified; the body short and round, compressed laterally; the skin rough, covered with mucus, but without spines; jaws undivided in the middle, forming a cutting edge; mouth small, the teeth adapted for bruising sea weeds and soft-bodied animals; the body is truncated posteriorly, looking as if it had

been cut off at the dorsal and anal fins and then furnished with a short broad caudal; there are no ventrals, no air bladder, and no abdominal sac capable of distention; the dor-



Common Sun Fish (Orthagoriscus mola).

sal and anal fins are more or less united to the caudal; the stomach is small, and immediately receives the biliary canal. The common sun fish (*O. mola*, Schn.) is almost circular, and the dorsal and anal project posteriorly, with the caudal between; on each side, near the centre, is a small pectoral, and in front of it the gill opening; the gills are arranged in comb-like fringes; it is also called moon fish and head fish. It grows 4 or 5 ft. in length and 3 or 4 ft. in depth, with a weight of several hundred pounds; the flesh is tough and remarkably elastic, owing to the great amount of yellow elastic fibre, intricately interlaced, almost to the exclusion of white fibre and true muscle; the liver is very fat, and its oil is used for lubricating purposes on board ship, and for sprains and bruises among fishermen. It is grayish above and whitish below, with a silvery lustre when alive, and phosphorescent at night. According to Mr. Putnam, in his paper read before the American association for the advancement of science in 1870, the young differ little from the adults in shape, and do not resemble *molacanthus*, as Lütken and Steenstrup have said. It is sluggish in its motions, and is often seen asleep at the surface of the water. In some seasons it is common in summer in Massachusetts and New York bays, and feeds partly if not principally on medusæ. There is probably no fish more infested by parasites, internally and externally.—The name sun fish is also commonly given to many medusæ (see JELLY FISH), and in this country to the bream (see BREAM).

**SUNFLOWER,** the common name of plants of the genus *helianthus*, a word of the same meaning. The genus belongs to the composite family, and consists of about 50 species, most of which are North American; they are coarse annual and perennial herbs, with rough stems and foliage, and some species bear tubers; the opposite or alternate leaves have three nerves; the solitary or corymbose heads are margined by conspicuous neutral ray flowers; the involucre imbricated; the persistent chaff of the receptacle embracing the four-sided akenes (popularly seeds), which bear at the top two chaffy and very deciduous scales, with sometimes two or more intermediate ones. In the common sunflower (*H. annuus*), from tropical America, the flat receptacle is 6 in. or more across, margined by conspicuous yellow ray flowers, while the central portion, or disk, is crowded with brownish tubular ones. The idea that the sunflower is so called because it always presents its face to the sun is erroneous; the name is more likely to be due to the resemblance of the flower head to the old pictorial representations of the sun as a disk surrounded by flaming rays. Few plants are so exhaustive of potash, the constituent in which most soils are deficient, as the sunflower, and its cultivation, sometimes recommended for various uses, would soon render fertile soils unproductive; for this reason it cannot become a profitable crop. It is raised in small quantities occasionally for the seeds (akenes), which make an acceptable variety in the food of poultry, and they are in repute among horsemen as a remedy for heaves, a quart being given daily with the food. Though the seeds yield about 40 per cent. of an oil useful for burning, for soaps, and other purposes, equally good oil may be obtained from plants which do not so exhaust the soil. The abundant pith has been used by French surgeons as a moxa. A so-called double variety, in which the tubular florets of the disk are developed in the same

Garden Sunflower (Helianthus multiflorus).

form as those of the ray, is much more showy than the common kind.—The best garden sunflower is the many-flowered (*H. multiflorus*), a perennial, of doubtful nativity, growing 4 to

6 ft. high, and producing late in summer an abundance of flowers, which in the double form have a close resemblance to the flowers of the dahlia. *H. argophyllus* of Texas, with hoary white foliage, and *H. orgyralis* of the far west, with narrow gracefully recurved leaves, are both sometimes cultivated for the peculiarities of their foliage. Numerous species, of interest to the botanist only, are to be found in all parts of the country, especially on the western prairies. The species cultivated for its edible tubers as Jerusalem artichoke (*H. tuberosus*) is described under ARTICHOKE.

**SUNFLOWER**, a N. W. county of Mississippi, intersected by the Sunflower river; area, 720 sq. m.; pop. in 1870, 5,015, of whom 3,243 were colored. Since the census a portion has been set off to form Leflore co. The surface is level and swampy, and the soil highly fertile. The chief productions in 1870 were 155,672 bushels of Indian corn, 21,091 of sweet potatoes, and 7,028 bales of cotton. There were 839 horses, 849 mules and asses, 1,728 milch cows, 3,497 other cattle, 184 sheep, and 7,828 swine. Capital, Johnsonville.

**SUNGARIA**, or **Dzungaria**. See TURKISTAN.

**SUNNA** (Arabic, custom or rule), a collection of oral traditions of the sayings and practices of Mohammed and his wives, companions, and immediate successors. The believers in them are called Sunnis. They are considered the orthodox Mohammedans, and comprise the four sects of Hanifites, Malekites, Shafeites, and Hanbalites, named after their founders, all of whom recognize the Sunna as of a value second only to that of the Koran, which the Shiahs deny. (See SHIAHS.) The Sunna is also known under the name *Hadis*, "Tradition." While the Shiahs constitute at present the majority of the Persian and Hindoo Mohammedans, the Sunnis, and among them especially the Malekites and Shafeites, are dominant in the Ottoman empire, Arabia, Turkistan, and Africa.

**SUNSTROKE** (Lat. *solis ictus;* Fr. *coup de soleil;* Ger. *Sonnenstich;* also called insolation, heat apoplexy, heat asphyxia, and solar asphyxia), an affection which suddenly attacks persons exposed to the continuous hot rays of the sun or other sources of heat. The symptoms vary considerably, according to the extent and nature of the injury. The patient is usually attacked in the midst of his employment, although sometimes he is not seized till in the night, especially if occupying heated and badly ventilated quarters. There is loss of consciousness, and generally stertorous breathing and convulsions, and in the worst cases there is extreme prostration of the vital powers, and the voluntary muscles are motionless from the paralyzed condition of the nervous system, the greatly impeded functions of respiration and circulation being the only signs of life. The attack usually comes on in the afternoon, partly because this is the hottest part of the day, and also because the subject has generally been laboring for many hours, and his vital powers are more or less exhausted. The attack may be immediately preceded by premonitory symptoms, such as pain and a feeling of fulness in the head and oppression at the pit of the stomach, sometimes attended with nausea and vomiting, and a feeling of weakness in the lower extremities, vertigo, and dimness of vision. In 60 cases reported to the New York hospital by Dr. H. S. Swift ("New York Journal of Medicine," 1854), surrounding objects appeared of a uniform color, generally blue or purple, but sometimes red, and at others green. In light cases the insensibility may be momentary, but in severe cases the patient rapidly becomes asphyxiated or comatose. The pupils are sometimes dilated and sometimes contracted, and there may be dilatation and contraction at different stages in the same case. There is considerable and often very great increase in the temperature of the body. In cases observed at Bellevue hospital, New York, in July, 1868, it frequently rose to 109·5° F., and in one instance to 110·5°; and still higher temperatures are recorded. When it reaches 107° recovery is scarcely to be expected, although it took place in the one instance at Bellevue where it reached 110·5°. Vomiting during the unconscious period, and involuntary evacuation of the bowels, are very grave symptoms. Although in many cases, as has been observed, the symptoms vary with the extent of the lesions, in the more pronounced cases they are rather uniform, the patient being completely without sensation or motion, except that of respiration, which is stertorous, though less than in true apoplexy. The eyes are fixed and turned upward with a glassy appearance; the pupils are greatly contracted, and the conjunctivæ are congested. Sometimes the whole system of voluntary muscles will be convulsed, and more rarely the patients appear to be in a state analogous to somnambulism; but the more fatal cases are often entirely free from motion of the voluntary muscles. In reports of cases occurring in the British army in India, by Mr. Longmore, in which he designated foul air of badly ventilated quarters as an active cause, the pathological conditions found after death were markedly more those of asphyxia than of congestive apoplexy, there being excessive engorgement of the lungs, while the cerebral congestion was decidedly less. The blood remains uncoagulated after death, showing a loss of life in its organic constituents. Thus, the post-mortem appearances accord with the symptoms, illustrating, as Mr. Barclay has pointed out, the four different ways in which death may take place, and furnish a key to the rational treatment of the different cases. 1. The intense heat of the sun's rays, pouring down upon the head, combined with great bodily exertion, may produce a state similar to that of nervous concussion from accident, and death may take place more or less sud-

denly by syncope. 2. When death does not quickly ensue, paralysis of the respiratory nerves may induce pulmonary congestion, terminating in asphyxia. 3. The cerebral may be much greater than the pulmonary congestion, and death may take place by coma. 4. Partial recovery may supervene, and the patient die in two or three days afterward, with serous effusion within the cranial cavity. Rather more than half the cases of sunstroke are fatal, death sometimes occurring in a few minutes, but oftener in a few hours, the average perhaps being from three to four, the patient remaining in a comatose state till the end of life.—The treatment has been a matter of much discussion, and for cases having marked apoplectic or comatose symptoms it is so still. Some contend that bloodletting may be advantageously employed, while others strongly oppose it in all cases, maintaining that there is always a degree of vital depression which forbids it. This is the position generally held by the surgeons of the English army in India. The principal remedies relied upon in nearly all countries are stimulation to the surface, especially along the spine, by sinapisms or blisters and electricity, and the administration of stimulant and purgative enemata containing alcoholic spirits; the bathing of the surface of the body with tepid or warm water containing ammonia or carbonate of soda; and the application of the cold douche to the spine and of cold to the head. The hair should be cut short, and in the worst cases blisters may be applied to the nape of the neck and along the spine. When the breathing is very difficult and the bronchial tubes are clogged with mucus, the patient should be often turned upon the side and face. Beneficial effects have sometimes been found from the inhalation of chloroform, but the use of this requires great caution. Promptness and decision are necessary, and the services of a physician should be procured as quickly as possible; but cold to the head, sinapisms, and stimulating enemata may be employed before his arrival.

**SUPERCARGO**, a person who accompanies a cargo shipped to a foreign port, and is intrusted with the sale of it there, either as specially directed or to the best advantage, and with the investment of its proceeds in a proper cargo for the home or other market. As the supercargo's authority properly concerns the cargo, it is ordinarily dormant during the voyage, and is called into exercise by arrival at the foreign port; and though for the sake of the cargo and a market the supercargo may sometimes have the authority to determine the destination of the ship, yet he has none to interfere in the navigation of her, or in any respect to usurp the office and functions of the master. The powers and duties of a supercargo are not very specifically regulated by law or usage, but are determined in every instance by the express instructions of the shipper where such instructions are given, as they usually are. The supercargo is simply an agent, and is limited like other agents to the authority vested in him by his principal. Yet, by construction of the law, new authority is conferred upon the supercargo by the existence and force of necessity; and it has been expressly held that if by any sudden emergency it becomes impossible for the supercargo to comply with the precise tenor of his instructions, or if a literal execution of them would defeat the objects of the shipper and amount to a sacrifice of his interests, it then becomes the duty of the supercargo to do the best he can for the shipper; and his acts done *bona fide* and with a reasonable discretion, in such an exigency, are binding upon the latter. A supercargo, like a master or foreign factor, generally buys and sells in his own name, and his acts in a foreign port, even after the death of the owner of the cargo, and while that event was unknown to him, are binding upon all parties.

**SUPERIOR, Lake,** the uppermost of the great border lakes of the United States and Canada, and the largest body of fresh water on the globe. It is included between lat. 46° 30′ and 49° N., and lon. 84° 50′ and 92° 10′ W.; greatest length from E. to W. 360 m.; greatest breadth, across its central portion, 140 m.; area, 32,000 sq. m. Its length of coast is about 1,500 m., its mean depth about 1,000 ft., and the level of its surface above the sea about 630 ft. The boundary line between Canada and the United States passes from Lake Huron up the St. Mary's river, the outlet of Lake Superior, through the centre of the lower half of this lake, to the mouth of Pigeon river on the N. shore, between Isle Royale and the Canadian coast. This island was allowed to fall on the American side of the boundary in compensation for one of the islands at the mouth of the St. Mary's river. The S. coast of the lake from the outlet to Montreal river belongs to the upper peninsula of Michigan. From this river to the river St. Louis the coast belongs to Wisconsin, and thence round to Pigeon river to Minnesota. Toward each extremity the lake contracts in width, and at the lower end terminates in a bay which falls into the outlet, the St. Mary's river, at the two opposite headlands of Gros Cap on the north and Point Iroquois on the south. Thence to the mouth of the St. Mary's at Lake Huron is about 60 m. Numerous streams flow into Lake Superior, but none of large size. High lands in general lie near the coast, the long slopes from which are directed away from the lake and the short slopes toward it. The rapid fall prevents the navigation even by canoes of most of these streams, but provides excellent water power, which is almost everywhere available. The principal rivers are the St. Louis, which enters at the head of the lake; on the N. shore, the Pigeon, Kaministiquia, Black Sturgeon, Nipigon (the outlet of Nipigon lake), Pic, and Michipicoten; and

on the S. shore, the Tequamenon, Sturgeon, Ontonagon, Montreal, and Bad. The coast of the lake is for the most part rocky, and on the N. side is much indented by deep bays surrounded with high rocky cliffs, back of which the country soon rises in bleak and dreary mountains. Numerous islands are scattered about this portion of the coast, many rising precipitously to great heights directly up from the deep water. Some present castellated walls of basalt, and some rise in granitic peaks to various elevations up to 1,300 ft. above the lake. Nowhere upon the inland waters of North America is the scenery so bold and grand as on the N. shore of Lake Superior. The irregularities of the coast with the general depth of water here afford numerous good harbors, which however in this unfrequented region are as yet of little service, while on the opposite coast such places of refuge are much wanted. The determination of the coast lines by the wearing action of the waters upon rocks of different degrees of hardness is remarkably exemplified everywhere along the shores of Lake Superior, particularly in the precipitous walls of red sandstone on the S. coast, famous in all the earlier accounts of the lake as the "Pictured Rocks." They stand opposite the greatest width of the lake and exposed to the greatest force of the heavy storms from the north. The effect of the waves upon them is not only seen in their irregular shapes, but the sand derived from their disintegration is swept down the coast below and raised by the winds into long lines of sandy cliffs. At the place called the Grand Sable these are from 100 to 300 ft. high, and the region around consists of hills of drifting sand. The principal bays are Thunder, Black, and Nipigon on the north, Tequamenon at the outlet, Keweenaw on the south, and Fond du Lac at the head. The largest islands are Isle Royale and Michipicoten. The most important places on the shores of the lake are Marquette, Mich., and Duluth, Minn. There are many varieties of excellent fish, the most valuable being white fish, sturgeon, and trout.—For the mineral productions of the Lake Superior region, see Copper Mines, vol. v., p. 323; Iron Ores, vol. ix., p. 407; Michigan, vol. xi., p. 497; Ontario, vol. xii., p. 635; and Silver, vol. xv., p. 57.

**SURAJAH DOWLAH.** See Clive, and India, vol. ix., p. 210.

**SURAT,** a walled town of British India, in the northern division of Bombay, in a collectorate of the same name (pop. in 1872, 554,000), on the left bank of the river Taptee, 20 m. from its mouth in the gulf of Cambay, and 150 m. N. of Bombay; pop. about 70,000. It contains an English church, several handsome mosques and temples, numerous Hindoo and other schools, and the Banian hospital, founded and richly endowed by the Jains for the treatment and cure of diseased animals. The city is an organized municipality, with a revenue of nearly £50,000.—Surat is of great antiquity, and is mentioned in the ancient Sanskrit poem, the *Ramayana.* When the Mohammedans ruled Hindostan it was their chief port of embarkation on their pilgrimage to Mecca. The Portuguese sacked Surat in 1530. In 1613 the English obtained commercial privileges from the emperor Jehanghir, and established a factory here which became their chief station on the W. coast of India, and remained so till 1686, when it was removed to Bombay. In 1796 the population was estimated at 600,000, and it had then greatly declined in consequence of the loss of its trade. In 1800 the administration of the government was permanently assumed by the British.

**SURETY,** in law, a person who binds himself to fulfil, either wholly or in part, the engagement of the principal obligor. For those cases in which the surety expressly assumes the obligation technically known as a guaranty, see Guaranty. When two parties join in making a purchase, or in giving a promissory note, each is in law equally liable to the party with whom the contract was made; but as between themselves, it is always competent for one to show that the transaction was wholly for the benefit and at the request of his co-obligor, and that he became bound as surety merely for his associate. If in such case the surety in face be compelled (as, according to the tenor of his obligation, he obviously may be) to pay the whole, equity declares that he is entitled to complete reimbursement from the principal, and that, in order to secure this reimbursement, the surety is entitled to the benefit of all the security which either the rules of law or the express acts of the parties have given to the obligee or creditor; and if, by any negligence or other acts, the obligee defeat these rights of the surety, he forfeits his right of action against him. If the creditor or obligee is fairly informed of the relation of principal and surety existing between the parties, he is bound to take care that no act of his shall destroy or lessen the surety's right of indemnity from the principal debtor. If therefore he declare that he will look solely to the principal for payment, so that the surety is induced to omit taking security from the latter; or if he tell the surety that the debt has been paid so that he relinquish to the principal his security; the surety will be in both cases discharged from his obligation to the obligee. But the mere inaction of the creditor to pursue his remedies against the principal will not discharge the surety, nor will positive indulgence to the principal have this effect; but if the delay be granted in pursuance of any binding agreement with the principal, so that the surety cannot pay the debt and then proceed at once for indemnity against the principal, the creditor's act releases the surety. And as the surety is entitled to the benefit of all securities given by the principal, he is discharged if the creditor's inaction or negligence have rendered these securities valueless. In short, though the

creditor is not bound, so far as the surety is concerned, to pursue the ordinary legal remedies against the principal, yet he is bound, in respect to all remedies given him by way of pledge or security or by other act of the parties, to hold or pursue them diligently in behalf of the surety; and if he relinquish any such remedy without the knowledge or against the will of the surety, he shall lose his claim against the latter to the extent of the right surrendered. Question has often been made whether the creditor would not lose his right against the surety if the principal should become insolvent after a request by the surety (which was disregarded) that proceedings be immediately taken for collection; but it has generally been held that he did not, and that the remedy of the surety was to pay the debt and then proceed to collect of the principal.

**SURF BIRD** (*aphriza virgata*, Gray), a wading bird of the plover family, and subfamily *cinclinæ* or turnstones. The bill is about as long as the head, with vaulted obtuse tip and compressed sides; wings long and pointed, with the first quill the longest; tail moderate and even; tarsi as long as middle toe, robust, with small irregular scales; toes long, free at the base, sides of anterior ones margined, and hind one elevated, slender, and partly resting on the ground. It is about 10 in. long, with the wing 7 in.; dark brown above, lighter on the wing coverts, with white spots and stripes on the head and neck; upper tail coverts and basal half of tail white, the latter terminated with brownish black; under parts white, tinged with ashy in front, each feather having a brownish black crescent. It is found on the Pacific coast of North and South America, and in the Hawaiian islands, and is migratory.

**SURGEON,** a bird of the stork family. See JACANA.

**SURGERY,** or **Chirurgery** (Gr. χείρ, the hand, and ἔργον, labor), that department of the art of healing which appertains to the diagnosis, prognosis, and treatment of the class of diseases which require manual or instrumental measures for their cure. The sphere of surgery is more limited and at the same time more accurately defined than that of medicine. Surgery divides tissues or parts improperly united, and unites those which have been divided when they should remain in union; separates whatever has become dangerous or inconvenient to the patient; removes foreign bodies, or parts of the body which from disease or loss of vitality have become foreign, whenever they exert a hurtful influence on the animal economy; restores to their cavity or replaces in their normal position portions of the body which have become displaced; checks the loss of blood from wounded or divided blood vessels; reduces inflammations, or removes the purulent or phlegmonous matter which may have been deposited by them; repairs and corrects deformities and distortions; and effects the replacement of lost tissues. Its means of accomplishing these results are the hand, lint, bandages, and apparatus of various kinds, cutting, crushing, and probing instruments, catheters, bougies, sounds, forceps, specula, &c., and the various forms of cauteries, direct and indirect, liquid and solid.—The earliest surgeons of whom there is any record were the Egyptian priests. According to Herodotus, we owe to them the use of the moxa and the adaptation of artificial limbs. Among the ancient Hebrews there is but little evidence of surgical skill, and that little was confined to the priests. In Greece, surgery is as ancient as the mythic period of its history. Chiron the centaur, born in Thessaly, and skilful in the application of soothing herbs to wounds and bruises, is the legendary father of Greek surgery. But Æsculapius, the son of Apollo, said by some to have been the pupil of Chiron, though others call him his predecessor and superior, won the highest fame in that early time for surgical skill. He is said to have been deified on account of his wonderful success about 50 years before the Trojan war. Temples were reared for his worship, which became the repositories of surgical knowledge, at Epidaurus, Rhodes, Cnidus, Cos, and Pergamus. Homer has immortalized his two sons, Podalirius and Machaon, the companions of Agamemnon in the Trojan war, where they rendered essential service in healing the wounds of the Grecian heroes. The Asclepiades, or reputed descendants of Æsculapius, retained the monopoly of surgery as well as medicine in their family. They had established in this period three schools of medicine, at Rhodes, Cnidus, and Cos. Pythagoras, in the 6th century B. C., established at Crotona a new school of medicine, in which his peculiar philosophy was probably applied to the art of healing; among its early pupils was Democedes, eminent as a surgeon, who when taken captive by the Persians reduced the dislocated ankle of Darius, and removed or in some way cured the cancerous breast of his queen Atossa, after the Egyptian physicians had failed. The want of anatomical knowledge, no dissections being allowed, was a fatal bar to any considerable progress in surgery. Hippocrates (about 400 B. C.) more than any of his predecessors advanced surgical treatment; he reduced dislocations and adjusted fractures, used the trephine, applied the forceps in accouchement, made incisions into the kidney for the removal of calculi, performed amputations, and perforated the cavity of the ribs in empyema and hydrothorax. Interdicted from human dissection, he practised the dissection of the ape tribe as nearest to man in anatomical structure, and thus obtained much knowledge. For a century after the death of Hippocrates we meet few names of note in surgery. The founding of the Alexandrian school under Ptolemy Soter about 300 B. C. was another important epoch in the advance of the art. Herophilus and Erasistratus, the

two great leaders of the medical school of that university, if it may be so called, were eminent both as physicians and surgeons; with them commenced the practice of human dissections. The extirpation of the spleen, and the application of remedies direct to scirrhosities and tumors of that viscus and of the liver, were among the bold operations of Erasistratus. To him also belongs the invention and application of the catheter in cases of retention of urine. The pupils of these eminent surgeons invented bandages of peculiar forms, and introduced the tourniquet and contrivances for reducing dislocations of the femur. One of them, Ammonius, employed an instrument for lithontriptic purposes, anticipating Civiale's process.—Rome in the first 700 years of its history produced no surgeon of note. Celsus, who flourished about the beginning of the Christian era, was the greatest of the surgeons of ancient Rome, and his observations on injuries of the head, on cataract, on the ligature of wounded arteries, hernia, lithotomy, fractures and dislocations, amputations, and carbuncle, show considerable knowledge. Aretæus, the first to use the cantharides blister, Heliodorus, Rufus the Ephesian, all of whom flourished between A. D. 50 and 120, and after them Antyllus, added to the surgical knowledge of the time new views of the treatment of injuries of the head, the resort to arteriotomy instead of venesection in sudden emergencies of inflammatory action, bronchotomy in some acute diseases of the throat, the radical cure of hydrocele by free incision of the parts, and a more thorough investigation of diseases of the kidneys and bladder. Galen devoted more attention to medicine than surgery, but his observations on hernia, on luxation of the femur backward, and on the application of the trephine to the sternum in empyema, are of importance. In the early period of Christianity surgery languished; the early Christians opposed dissection as strongly as the pagans, and by attributing the power of healing wounds to martyrs and their relics discouraged all efforts at improvement in surgical science. The first eminent name among the surgeons of the dark ages is Aëtius (500 to 550), whose surgical writings are numerous and valuable. He practised scarification of the extremities in anasarca, operated for aneurism, endeavored to dissolve urinary calculi by internal remedies, discussed hernia with great ability, and wrote on encysted tumors, injuries to nerves and tendons, diseases of the eyes, &c. Alexander of Tralles, a younger contemporary of Aëtius, wrote treatises, now lost, on diseases of the eye and on fractures, which were highly commended for their originality by some of his successors. Paulus Ægineta, in the 7th century, was a surgeon of eminence and considerable originality. His sixth book has been considered by many as the best body of surgical knowledge prior to the revival of letters. He recommended topical in preference to general bleeding, as more effective in reducing local inflammation; resorted to copious venesection to accelerate the painful descent of calculi through the ureters; opened internal abscesses with caustics; defined the points for performing paracentesis in ascites; made his incision in lithotomy on one side of the raphe instead of the centre as Celsus had recommended; practised both laryngotomy and tracheotomy, the latter as a means of carrying on respiration during occlusion of the larynx; treated of fractures of the patella; and was the originator of the obstetric operation of embryotomy.—The Arabian physicians, who rose into distinction as those of the West declined in reputation, did little for surgery. Rhazes (about 900) described for the first time *spina ventosa* and *spina bifida*, cauterized the wounds from the bites of rabid animals, opposed the use of the knife in cancer except when limited and when the whole tumor could be removed, and gave a clear and satisfactory description of the treatment of hernia. Avicenna (died about 1036) introduced the flexible catheter. Albucasis (died about 1106) introduced an instrument for the cure of *fistula lachrymalis*, invented the probang, and in wounds of the intestine practised union of the divided parts by suture with success.—In Catholic Europe medical practice and what of surgery remained was mostly in the hands of the clergy until, by the edict of the council of Tours in 1163, they were interdicted from all surgical practice. The Jews were at this period and for a century or two later in high repute as physicians, but they seem to have had a dislike to surgery. Guy de Chauliac, a priest, compiled from the Greek and Arabian authors the earliest work of modern times on surgery, but with very little judgment of what was worth retaining. For two centuries and more surgery was mainly in the hands of the illiterate barber surgeons. The revival of surgical science dates from the appearance of Vesalius (died 1564) as a teacher of anatomy in Italy, followed soon after by Fallopius and Eustachius. Surgery was then for the first time put upon a sound and scientific basis, that of careful dissection, and Ambroise Paré, a French army surgeon who had educated himself in anatomical science, was the first of its great lights. He was surgeon successively to four kings of France, and was attached to the French armies as surgeon-general down to 1569. To him we owe the revival and improvement of the practice of tying the arteries after operations or wounds, instead of cauterizing them with hot iron or boiling oil. The pupils of Paré added little lustre to their master's name; but in Italy at the close of the 16th century Fabricius ab Acquapendente flourished at Padua, and his *Opera Chirurgica*, the first really valuable treatise on surgery of modern times, passed through 17 editions. He was the preceptor of Harvey. Wiseman, sergeant surgeon to Charles II., was the first eminent sur-

gical writer and practitioner in England. His recommendation of immediate amputation in military practice, when the preservation of the limb was impossible, has been followed from that time to the present. He left eight treatises on surgery, which are not without value even at the present day. The flap operation in amputation is claimed for James Young, an English surgeon contemporary with Wiseman, and also for two French surgeons, Verduin and Sabaurin, of the same period. In Germany during this century, Hildanus, Scultetus, Purmann, and Heister were the principal surgical writers and practitioners. In Italy the principal names of note toward the close of the 16th and in the 17th century were Taliacotius, the originator of the restorative surgery in Europe; Cæsar Magatus, who greatly simplified the treatment of wounds; and M. A. Severinus, who banished the salves and plasters which in Italy had usurped the place of operations. The 18th century witnessed a still greater advance in the science. In England, Percival Pott, well known for his investigation of that form of caries of the vertebra known by his name (see SPINAL DISEASES), and the most judicious writer of modern times on fractures, amputations, injuries of the head, and diseases of the spine; John and William Hunter, the former the greatest master of the principles of surgery in the profession; Cheselden and Douglas, both famous as lithotomists; and the two Monros, father and son, are among the great names of the surgical profession. In France flourished La Peyronie, at whose instance Louis XV. in 1731 founded the academy of surgery; Jean Louis Petit, the greatest French surgeon of the 18th century; Ledran, Garangeot, and the illustrious Desault, the originator of clinical surgical instruction and the inventor of numerous admirable apparatuses for the treatment of fracture. Among the celebrated surgeons of other European countries were Molinelli, Morgagni, Scarpa, Bertrandi, and Moscati in Italy; Deventer, Albinus, and Camper in Holland; and Platner, Röderer, Rambilla, Theden, and Richter in Germany. During the 18th century the ligature of aneurismal arteries of large size, the treatment of hernia and *fistula in ano*, the cure of *fistula lachrymalis*, and the skilful management of dangerous and difficult parturitions, were the most important branches of surgery in which there was a material advance from the preceding century; the proper construction of instruments also received great attention. The 19th century has, however, done more for the improvement of this science than all the centuries which have preceded it. In England, Abernethy, Sir Astley Cooper, Liston, and others of the highest reputation have passed away, and others hardly less eminent remain; in France, Dupuytren, Roux, Lisfranc, and Larrey have had no superiors either before or after them. The following may with propriety be particularized as among the improvements of the age in surgery: the introduction of anæsthesia; resection of the bones at the joints; the preservation of the periosteum and consequent development of new bone; partial amputations of the foot, as instanced in the operation of Lisfranc for the removal of the metatarsus, and of Chopart, Symes, Malgaigne, and Pirigoff for disarticulation of tarsal bones; the amputations at the thigh and shoulder joints; the ligature of arteries within the trunk and immediately at their departure from it; the resection and removal of portions or even the whole of the upper or lower jaw; the operations for cleft or deficient *velum palati* or palatine vault; the opening by longitudinal section of the air passages at different points to avoid asphyxia; the resection and extirpation of the uterus, of the ovaries, and of the lower portion of the rectum; the introduction of the silver suture, especially in operations on the viscera, as for recto-vaginal and vesico-vaginal fistulæ; the adoption of the immovable apparatus for fractures; the processes for remedying disunited fracture; the substitution of milder means for the trephine in all except the most serious cases; the improved treatment of ulcers and abscesses; the cure of the most formidable aneurisms by the ligature of the carotid, subclavian, axillary, humeral, and external and internal iliacs; the treatment of varicose veins; the successful treatment of calculus by lithotrity, in consequence of the great improvements made in the processes and instruments; the diagnosis and treatment of tumors, whether encysted, fatty, vascular, or malignant; the cure of strabismus, and the generally improved treatment in diseases of the eye, including the invention of the ophthalmoscope by Helmholtz in 1851, and the reformation of ophthalmic medicine and surgery carried on by Von Graefe, Donders, Bowman, Toynbee, Wilde, Von Tröltsch, Politzer, and others; the restorative processes, by which the nose, lip, and other parts are reformed from adjacent tissues; the treatment of harelip and of club-foot; and the notable advance consequent upon the conservative treatment of gunshot and other wounds of the brain.—As from the nature of their duties suits for malpractice are more often brought against surgeons than against physicians, it will be appropriate here to speak of their legal obligations, though the same laws apply to practitioners in any of the branches of medicine. In undertaking the treatment of a patient, the surgeon enters into a legal obligation and assumes legal liabilities, which, though seldom expressly defined, are yet, in the apprehension of the law, fixed and certain. The law holds that he contracts for the possession of that reasonable degree of learning, skill, and experience which the members of his profession ordinarily possess. Those also who, like oculists, aurists, or dentists, claim to be particularly conversant with and skilful in the treatment of the diseases of single organs, must be held

to a peculiar responsibility. The same is true of surgeons of great pretensions in large cities as compared with those residing in remote and thinly settled districts. In undertaking a case, the surgeon also contracts that he will apply the skill which he possesses, whatever be its degree, with reasonable and ordinary diligence and care. Extraordinary care is no more implied than extraordinary skill; nor is the practitioner supposed to guarantee a cure, though he may if he chooses contract to effect a cure, and then he must answer for a failure. The practitioner's skill in any case will ordinarily be required to embrace those phases and phenomena which usually characterize the dominant disease; and any mischance which connects itself immediately with these will involve the question of skill. His diligence and care will be exercised in watching for and guarding against the accidental influences which, if overlooked, may delay or even prevent the restoration of the patient. If he have brought ordinary skill and care to the treatment of his case, the surgeon is not responsible for want of success nor for mistakes in cases of real doubt and uncertainty. The surgeon's liability in cases of malpractice is ordinarily only a civil one, and the injury he does can usually be compensated by damages. But, in cases where death has followed the treatment, and it has seemed to be the direct consequence of the treatment, there have been, not unfrequently, charges of criminal malpractice preferred against the medical practitioner. To constitute a crime, there must be a malicious or criminal intent. This intent may exist in an actual design, or the law will infer it from gross rashness or want of circumspection.—Where no statutory prohibition intervenes, all regular and irregular practitioners are to be placed on the same footing. Leaving out of consideration cases of express malice, which would hardly be included under the designation of malpractice, our topic is reduced to those cases in which the charge is founded upon gross ignorance, gross negligence, or gross rashness. With particular reference to the charge of manslaughter, the law, especially in England, is that "if one, whether a medical man or not, profess to deal with the life or health of another, he is bound to use competent skill and sufficient attention; and if he cause the death of the other through a gross want of either of these, he will be guilty of manslaughter;" or as an eminent American authority, Mr. Bishop, states the law: "The carelessness in a medical man which, if death follow, will render him liable for manslaughter, is gross carelessness, or, as it is more strongly expressed, the grossest ignorance or most criminal inattention."

**SURICATE,** a carnivorous mammal of South Africa, coming near the ichneumons. It is the *ryzæna (suricata) capensis* (Ill.), and is sometimes called zenick. It is about a foot long, with a tail of 6 or 8 in., and about 6 in. high; it is nocturnal, dwelling in burrows which it excavates with its stout claws; the color is grayish brown, tinged with yellow, with obscure dark bands across the back. It is docile

Suricate (Ryzæna capensis).

and intelligent, and is often domesticated for the destruction of vermin.

**SURINAM, or Dutch Guiana.** See GUIANA.

**SURINAM,** a river of Dutch Guiana, which rises in the mountains on the S. frontier, flows through the centre of the colony, and falls into the Atlantic about 10 m. below Paramaribo after a course of about 300 m. It has several tributaries, and is navigable for large vessels about 30 m. from its mouth.

**SURREY,** a S. E. county of England, bordering on Middlesex (from which it is separated by the Thames), Kent, Sussex, Hampshire, and Berkshire; area, 748 sq. m.; pop. in 1871, 1,090,270. That part of the county which lies on the Thames, with much of the land on the borders, is exceedingly fertile. Parts of the shire are famed for the beauty of their scenery. The principal streams are the Wey, Mole, and Wandle, which fall into the Thames. There are extensive market gardens and flower farms, where besides flowers medicinal herbs are raised in large quantities. Numerous canals and railroads intersect the county. Silk, woollen goods, hosiery, paper, earthenware, leather, and ale are manufactured. Besides Southwark, Lambeth, and other portions of London, the most important places are the three county towns, Guildford, Croydon, and Kingston, and Epsom, Reigate, Farnham, and Godalming.

**SURREY, Henry Howard,** earl of, an English poet, born about 1516, beheaded on Tower hill, London, Jan. 21, 1547. He was the eldest son of Thomas Howard, third duke of Norfolk, and passed his youth at the court of Henry VIII. In 1532 he married the daughter of the earl of Oxford, and went to France with the duke of Richmond. He assisted in the trial of Anne Boleyn in 1536, served in France in 1540, and was imprisoned for some wild irregularities in 1543. In 1544 he commanded in France, and earned the rank of field marshal. After the taking of Boulogne he became its governor, and continued the

war with advantage until January, 1546, when he met with a reverse. A panic among his troops caused a failure to intercept a convoy of provisions near St. Étienne, and his rival, the earl of Hertford, afterward the protector Somerset, induced the king to recall him to England. Surrey's comments on this action offended Henry, who imprisoned him for a short time in the tower. The Hertford faction lost no opportunity to excite the fears of the king, and on Dec. 12, 1546, Surrey with his father was again arrested on a charge of treason, for having quartered the royal arms with his own. Surrey in an eloquent defence proved conclusively his right to assume the royal arms; yet he was condemned and executed about a week before the death of the king. His works consist of sonnets, amatory verses, elegies, paraphrases from the Scriptures, and translations of the second and fourth books of the Æneid, and afford the first instance of the use of the sonnet and of blank verse in English poetry. The first edition of his sonnets was published by Richard Tottel in 1557. Editions of his works, with those of Sir Thomas Wyatt, and biographies, have been published by George Frederick Nott, D. D. (2 vols. 4to, 1815–'16; new ed., 1871), Sir Harris Nicolas (1831), Prof. Child (Boston, 1854), and the Rev. R. Gilfillan (Edinburgh, 1856).

**SURROGATE.** See PROBATE.

**SURRY.** **I.** A S. E. county of Virginia, bounded N. E. by James river and S. W. by Blackwater river; area, 340 sq. m.; pop. in 1870, 5,585, of whom 3,192 were colored. The surface is moderately hilly and the soil fertile. The chief productions in 1870 were 85,995 bushels of Indian corn, 44,666 of peas and beans, 15,773 of Irish and 3,381 of sweet potatoes, and 1,104 lbs. of wool. There were 452 horses, 724 milch cows, 1,113 other cattle, 1,032 sheep, and 4,073 swine. Capital, Surry Court House. **II.** A N. W. county of North Carolina, bordering on Virginia, bounded S. by the Yadkin and drained by Ararat and Fisher rivers; area, about 500 sq. m.; pop. in 1870, 11,252, of whom 1,560 were colored. The surface is in part mountainous and generally hilly. Ararat or Pilot mountain in the southeast is the highest peak in this region. The chief productions in 1870 were 26,701 bushels of wheat, 18,029 of rye, 190,171 of Indian corn, 39,321 of oats, 14,707 of Irish and 15,368 of sweet potatoes, 254,286 lbs. of tobacco, 12,690 of wool, 81,238 of butter, 5,183 of flax, 68,658 of honey, and 9,681 gallons of sorghum molasses. There were 1,129 horses, 2,178 milch cows, 3,989 other cattle, 6,414 sheep, and 11,634 swine; 3 manufactories of cotton goods, 5 of chewing tobacco, and 4 flour mills. Capital, Dobson.

**SURVEYING** (Fr. *survoir*, to overlook), the art of measuring portions of the surface of the earth, either for the purpose of calculating the contents of areas, of laying out tracts of required extent, of establishing roads, or of preparing maps. The ancient science of geometry grew out of the practice of surveying, and now embodies the mathematical principles upon which the work is conducted. This science was cultivated by the Egyptians at a very early period, and many of the old Greek writers ascribe its origin to changes which annually took place from the inundation of the Nile, and to the consequent necessity of adjusting the claims of each person respecting the limits of lands. The progress of the art of surveying to its higher application in determining the figure of the earth has been traced in the article EARTH; and the operations in trigonometrical surveys upon a grand scale are described under COAST SURVEY.—The systems of surveying may be classed according to its special objects; as land surveying, for determining the contents of areas, or dividing tracts into lots of smaller dimensions; topographical surveying, which includes the measurement of horizontal lines and angles, and the variations of level, so that the superficial inequalities may be graphically represented; hydrographical or maritime surveying, the object of which is the determination of the positions of channels, shoals, rocks, and the shore line; and mining surveying, for fixing the positions of the underground works in mines, so that these can be correctly mapped. Surveys extending over large territories involve the consideration of the curvature of the earth and the use of spherical trigonometry, and are called geodetic in contradistinction from ordinary surveying over more limited areas, which may with sufficient accuracy be conducted without reference to the figure of the earth, and which may be termed plane surveying. (See GEODESY.) These systems all involve the same principles of measuring lines and angles between definite points upon the area included in the survey, and reproducing these upon paper, reduced to a convenient scale. Calculating the content of the area is commonly the conclusion of the work of land surveying. Tracts of any shape or size may be accurately surveyed, if tolerably level and clear, with no other instrument than the surveyor's chain (see GUNTER, EDMUND); and for this may be substituted a measuring tape, a measured rope, or leather driving reins. This is done by measuring all the sides of the tract, and then diagonals from one corner to another, so selected as to divide the tract into triangles as nearly equilateral as possible. The number of diagonals will be two less than the number of sides. In using the chain it is to be kept as nearly horizontal as possible, or if the measurement is made on a slope the variation from the horizontal is to be determined and duly allowed. In case the corners are not visible from each other, intermediate points may be adopted and used for the terminations of lines from corners, the object being in every case to divide the tract into triangles of which the sides are all measured. Proof lines measured

from a corner of each triangle to the opposite side serve to rectify the other measures of the triangle, and if perpendicular to the side afford a convenient means of calculating upon the ground the area of the triangle. Perpendiculars to any line are readily laid out with a chain, as carpenters and masons draw right angles by what they call the 6, 8, and 10 rule, the popular application of the principle of the square of the hypothenuse being equal to the sum of the squares of the two other sides. The method is to measure from the point where the perpendicular meets the line, either along this line or along the perpendicular, a distance equal to six units of any kind, and then upon the other of these lines a distance of eight units. The two lines are perpendicular to each other when the two termini are just ten units apart. Convenient distances for this measurement might be 3, 4, and 5 rods or chains, or any similar multiples of these numbers, as 21, 28, and 35. Other trigonometrical methods readily suggest themselves. A number of convenient instruments of simple form, known as the surveyor's cross, are in use for setting out perpendiculars by lines of sight, crossing each other at right angles; and a temporary substitute for them is easily made by sticking a pin in each corner of a square piece of board, and sighting across these in the direction of the line and at right angles to it. Angles in the field are determined by a chain, by measuring a "tie line" from a measured point on one side to another measured point on the other side. By this means the boundaries of a tract may be determined when it cannot be conveniently measured off in triangles. A great variety of expedients are adopted for overcoming natural obstacles and determining the extent and shape of inaccessible objects, systems of triangles being in such cases formed outside of and around such objects. Crooked lines are determined by means of perpendicular offsets measured from different points along a straight line run as nearly coincident to the crooked line as may be. In all the methods of surveying, the measurements, together with various incidental observations, are recorded, after some established system, in what are called field notes, and from these the results of the survey are afterward plotted to a convenient scale.—A more common system of surveying is that in which instruments for taking angles are employed in connection with the chain. A graduated horizontal circle, with a straight edge called an alidade turning upon its central point, which may be conveniently sighted along, furnishes the means of ascertaining the angular distance of two lines, the instrument being set at their intersection, and the alidade pointed in the direction of one and then of the other. This involves the principle of the engineer's transit, or of the theodolite. (See Theodolite.) With these instruments angles can be determined with great accuracy, especially when the observations are repeated by reversing the instrument and taking the mean, each including the reading of both verniers. With the transit and the chain for measuring distances, a tract of almost any dimensions is accurately surveyed by measuring the angles at its corners, and the correctness of the work is proved when the sum of all the interior angles is found equal to the product of two right angles, or 180°, by the number of sides of the tract less two; or if the instrument be used by the method called traversing, or "surveying by the back angle" (which consists in noting the angle which each successive line makes, not with the preceding line, but with the first line observed, which is hence called the meridian of the survey), then the reading, on getting round to the last station, and looking back to the first line, should be 360°, or 0°. A compass and chain may be employed in filling up the interior details of a large survey with the transit; and the compass may be used for determining the magnetic bearing of one of the lines, unless this be astronomically ascertained by observations of the north star or of the shadows before and after noon. The compass is the instrument in most common use in ordinary surveying. The magnetic needle, wherever the instrument is set, establishes the meridian line, and from this, the sights of the instrument being turned to any other line, the angle of divergence is read on the graduated circle around the compass box. This instrument has been described under its own name; also the more perfect instrument, in which its inaccuracies are obviated, under the head of Compass, Solar.—The details of surveys are variously modified according to the extent of the area, character of the ground, &c. With the transit or compass, the boundary lines may be all followed out, the angles they make with each other determined, and their lengths measured by the chain; the points of crossing of roads, brooks, fences, &c., measured, and the bearings of these objects taken; and increased accuracy may be given to the work by running diagonal or proof lines, as in chain surveying. Additional checks are furnished by taking at each station the bearings of some marked objects, which when the work is plotted should severally fall at the points of intersection of the lines directed toward these objects from the several stations. Sometimes a tract may be surveyed from a measured base line, either a line within or without it, or one of the boundary lines, by placing the compass successively at each end of this line and taking the bearings of each corner; or without a compass the work may be very conveniently performed with approximate correctness by the plane table method, provided no angles are taken less than 30° nor larger than 150°. A drawing board covered with paper is set up at one end of a measured base line, and a ruler furnished with upright sights at each end, exactly over the drawing edge, is set with this

edge against a fine needle stuck up in the board, and is then directed successively toward the corners of the tract to be surveyed and any other prominent objects, toward which from the needle lines are to be drawn on the paper. One of these lines should also be in the direction of the measured line. The instrument is then taken to the other end of the measured line, the needle is removed along the last line named on the board a distance corresponding, according to the scale adopted, to that of the measured line on the ground, and the board is so placed as to make the line toward the former station correct. The ruler is then again pointed to the same objects, and lines are drawn toward each from the new position of the needle. Their intersections with the former lines designate the places of these objects on the plane. The plane table is used in various other ways, as by moving it from one corner to the next, and placing it at each so that the last line drawn coincides with that in the ground. From any central point also radiating lines may be measured to the corners, and the distances measured and marked off according to the proper scale.—Rivers, brooks, and roads are surveyed by measuring a succession of lines following their general course, and taking offsets from the sides of the line. Streets are followed in a similar manner. Distances are sometimes measured upon roads, where expedition is more important than extreme accuracy, by various substitutes for the chain, some of which, as the odometer and pedometer, have been noticed under the former head. One may soon accustom himself to pace in straight lines, and with steps of uniform lengths, the most exact method being to regulate the natural step, rather than to try to attain one of any determinate length. The usual average step of a man is that of the English military pace, 2½ ft. The French geographical engineers accustom themselves to take regular steps of $\frac{8}{10}$ of a metre, or 2 ft. 7½ in.—The field work being completed, the figure of the tract surveyed is reproduced upon a diminished scale by what is termed plotting; and from this plot the contents are ascertained by a series of mathematical calculations applied successively to the several divisions, or by the method of calculation of latitudes and departures, for which a table of natural sines is required, unless "traverse tables" giving the latitude and departure for any bearing, as furnished in some books on surveying, are at hand. An approximate estimate of the number of acres included in the survey is sometimes made by drawing the plan upon sheet lead of uniform thickness, or upon Bristol board or heavy paper, cutting out the piece on the boundary lines, and weighing it in a delicate balance. The weight may then be compared with that of a similar piece that exactly comprises a definite number of acres, laid out upon the same scale.—The extensive territories of the United States are surveyed upon a peculiar system, planned with reference to the division of the lands into squares of uniform size, so arranged that any tract of 160 acres, or a "quarter section," may have its distinct designation and be readily found upon the map or recognized upon the ground by the marks left by the surveyors. Each great survey is based upon a meridian line run due N. and S. by astronomical measurements the whole extent of the survey in these directions; and upon a "standard parallel" or base line running E. and W., similarly established with great accuracy. Parallels to these lines are run every 6 m., usually with the solar compass corrected by frequent celestial observations; and thus, as nearly as the figure of the earth admits, the surface is divided into squares of 6 m. N. and S. and the same E. and W., each one containing 36 sq. m. or sections, into which the territory is further divided by meridians and parallels run at every mile; while the half mile being marked on these lines by setting what is called a quarter post, the points are established for the subdivision into quarter sections. The squares of 36 sq. m. are termed townships, often contracted to "towns;" and each line of them E. and W. is numbered either N. or S. from the base line, and each line of them N. and S. is termed a range and is numbered E. or W. from the meridian. The N. and S. lines bordering the townships are known as range lines, and the E. and W. as township lines. Each survey is designated by the meridian on which it is based, and of these principal meridians there are 6 designated by numbers and 18 by special names. The following table, compiled from information furnished from the general land office in August, 1875, gives the designation of the meridians, their longitude W. from Greenwich, and the N. latitude or other description of the principal base lines:

| DESIGNATION OF PRINCIPAL MERIDIAN. | Longitude W. fr'm Greenwich. | Principal base lines, N. lat. |
|---|---|---|
| First, boundary bet. Ohio and Indiana.. | 84° 51′ | ........................ |
| Second, through Indiana ............ | 86° 28′ | ........................ |
| Third, through Illinois | 89° 10′ 30″ | ........................ |
| Fourth, N. from mouth of Illinois river .... | 90° 29′ 56″ | 38° 58′ 12″ |
| Fifth, N. from mouth of Arkansas river.. | 90° 58′ | Mouth of St. Francis R. |
| Sixth ............... | 97° 22′ | 40° |
| Michigan............. | 84° 19′ 9″ | 7 m. N. of Detroit. |
| Tallahassee.......... | 84° 18′ | Tallahassee, Fla. |
| St. Stephen.......... | 88° 2′ | 31° |
| Huntsville........... | 86° 31′ | N. boundary of Alabama. |
| Choctaw ............ | 89° 10′ 30″ | 29 m. S. of Jackson, Miss. |
| Washington......... | 91° 5′ | 31° |
| St. Helena, S. from base ............ | 90° 11′ | 31° |
| Louisiana........... | 92° 20′ | 31° |
| New Mexico......... | 106° 52′ 9″ | 34° 19′ |
| Great Salt Lake ..... | 111° 53′ 47″ | 40° 46′ 4″ |
| Boisé............... | 116° 20′ | 43° 26′ |
| Mt. Diablo .......... | 121° 54′ | 37° 53′ |
| San Bernardino...... | 116° 56′ | 34° 6′ |
| Humboldt........... | 124° 11′ | 40° 25′ 30″ |
| Willamette.......... | 122° 44′ | 45° 30′ |
| Montana ........... | 111° 38′ | 45° 46′ 27″ |
| Gila and Salt river.... | 112° 15′ 46″ | 33° 22′ 57″ |
| Indian.............. | 97° 15′ 56″ | 34° 31′ |

The 36 sections of each township are numbered in order, beginning with the N. E. corner and thence proceeding along the N. side of the township to section 6 in the N. W. corner; section 7 begins the next line of sections S., the numbers running E. to 12, and then beginning the third line with 13 and running W. to 18, and so on, bringing No. 36 in the S. E. corner of the township. The quarter sections are designated by their position as N. E., N. W., S. E., and S. W. Fractional sections of irregular shapes are admitted on the borders of lakes, rivers, &c. With these explanations any tract may be readily pointed out upon the government maps from its abbreviated description, or any locality in the wildest territory may be correctly defined; thus the S. W. qr. sect. 13, T. 66 N., R. 34 W., meridian Michigan, is traced directly to an old mining location near the N. E. extremity of Isle Royale, Lake Superior. The law which established this system, while it required that the N. and S. lines should be true meridians, also required that the townships should be six miles square. To satisfy both of these conditions is physically impossible, for the figure of the earth causes the meridians to converge toward the pole, thus making the N. line of each township shorter than its S. line; an inequality which becomes more and more marked the higher the latitude of the surveys. Provision is consequently made for correcting the errors thus caused, by establishing what are called correction lines, which are parallels bounding a line of townships on the north when lying N. of the principal base, or the S. line of townships when lying S. of the principal base, from which the surveys as they are continued are laid out anew, the range lines again starting at correct distances from the principal meridian. In Michigan these correction lines are repeated at the end of every tenth township, but in Oregon they have been repeated with every fifth township. The instructions to the surveyors have been that each range of townships should be made as much over 6 m. in width on each base and correction line as it will fall short of the same width where it closes on to the next correction line N.; and it is further provided that in all cases where the exterior lines of the townships shall exceed or shall not extend 6 m., the excess or deficiency shall be specially noted and added to or deducted from the western or northern sections or half sections in such township, according as the error may be in running the lines from E. to W. or from S. to N. In order to throw the excesses or deficiencies on the N. and on the W. sides of the township, it is necessary to survey the section lines from S. to N. on a true meridian, leaving the result in the N. line of the township to be governed by the convexity of the earth and the convergency of the meridians. Navigable rivers, lakes, and islands are "meandered" or surveyed by the compass and chain along the banks.—The instruments employed on these surveys, besides the solar compass, are a surveying chain 33 ft. long of 50 links, and another of smaller wire as a standard to be used for correcting the former, as often at least as every other day; also 11 tally pins made of steel, telescope, targets, tape measure, and tools for marking the lines upon trees or stones. In surveying through woods, trees intercepted by the line are marked with two chops or notches, one on each side; these are called sight or line trees. Other trees near by not touched by the line are blazed on two sides, quartering toward the line; but if at some distance from the line, the two blazes should be near together, on the side facing the line. These are generally found to be permanent marks, not only recognizable for many years, but carrying with them their own age by the rings of growth around the blaze, which may at any subsequent time be cut out and counted as years; and the same are recognized in courts of law as evidence of the date of the survey. They cannot be obliterated by cutting down the trees or otherwise without leaving evidence of the act. Corners are marked upon trees if found at the right spots, or else upon posts set in the ground, and sometimes a monument of stones is used for a township corner and a single stone for section corners; mounds of earth are made where there are no stones nor timber. At the corners the four adjacent sections are designated by distinct marks cut into a tree, one in each section. These trees facing the corner are plainly marked with the letters B. T. (bearing tree) cut into the wood. Notches cut upon the corner posts or trees indicate the number of miles to the outlines of the township, or, if on the boundaries of the township, to the township corners.—A useful text book is the "Treatise on Land Surveying" of W. M. Gillespie (new ed., New York, 1875).

**SURVILLE, Marguerite Éléonore Clotilde de Vallon-Chalys de,** a French lady of the 15th century, the reputed authoress of remarkable posthumous poems first collected in 1803 by Vanderbourg. They have been ascribed to her descendant, the marquis Joseph Étienne de Surville, a royalist executed in 1798, and with less probability to the publisher Vanderbourg himself. The poems are in the style of the 15th century, and refer to Clotilde's husband Bérenger de Surville, who fell during the defence of Orleans against the English. Other parts of them are believed to apply to the persecutions endured by Louis XVI. The publication has given rise to a long controversy, but even those who, like Villemain and Sainte-Beuve, question its genuineness, unite in praising the genius of the work.

**SUS,** a territory of Morocco, comprising the Atlantic coast of that country between the Atlas mountains and the river Asaka or Nun, and extending E. to the country called Draa; area, about 11,500 sq. m.; pop. estimated at 750,000. It is mostly mountainous, the climate

is healthful, and the soil generally good. The principal productions are the cereals and legumes, and the date, olive, argan, fig, almond, and grape. The mountains are rich in minerals, particularly copper and lead, and there are numerous mines which were anciently worked. The inhabitants, who are Shelloohs or Berbers and Arabs, are more austere and more warlike than others of the Moroccans, and use neither tobacco, liquors, nor coffee. They possess but few cattle or sheep. Tarudant, the chief city, a walled town with five gates, is in the valley of the river Sus, 44 m. from the coast. The N. part of Sus, above the river Gaz, is ruled by the governor of Tarudant under the authority of Morocco. Tazeroualt, S. of the Gaz, is governed by a nominally independent sovereign, and the remainder is under independent sheiks.

**SUSA** (Gr. *τά Σοῦσα*, the city of lilies), an ancient city of Persia, the Shushan (Heb., lily) of the Scriptures, the capital of the province of Susiana, and one of the residences of the court. It was between the Choaspes (the modern Kerkha) and the Coprates (Abzal, an affluent of the Karun), enjoyed a fine climate, and was one of the largest cities of the Persian empire. Strabo says it was 120 stadia in circumference, and surrounded with a wall of burnt brick. According to Pliny, it was founded by Darius Hystaspis, though others make Tithonus, the father of Memnon, its founder. It was for a long period the chief treasury of the Persian empire. In 325 B. C., when visited by Alexander, it possessed immense wealth, and from its plunder he gave largesses to his soldiers and presents of great value to his generals on the occasion of his marriage with Barsine and Parysatis. There has been considerable controversy as to the site of the ancient city, but the discovery by Sir. W. F. Williams and Mr. W. K. Loftus of a gigantic tumulus and cuneiform and Greek inscriptions at the modern Sus, E. of the Kerkha, establish that as the locality of Susa, over Shuster, which was formerly suggested as a probable site.

**SUSIANA** (also *Susis* and *Cissia*), an ancient province or region of Persia, of great extent, mountainous in the northeast, but mostly a plain, lying between the Zagros mountains and the Tigris, bounded N. by Media and S. by the Persian gulf. It nearly corresponded to the modern province of Khuzistan. It was drained by the Pasitigris (supposed to be the lower Karun), the Eulæus (the upper Karun), the Choaspes (Kerkha), the Coprates (Abzal), the Hedypnus (Jerrahi), and the Oroatis (Tab). Its earliest inhabitants were the Elymæi, probably the Elamites of Scripture, a portion of whom still occupied it in the time of Strabo; the other tribes mentioned as settled in the province are the Susii, who were agriculturists and had their villages on the plain, and the Cissii, Cossæi, Uxii, and Messabatæ, all predatory mountaineers. (See ELYMAIS, and KHUZISTAN.)

**SUSO, Heinrich**, a German ascetic writer, also known as Brother Amandus, but whose real name was Von Berg, born in Ueberlingen, on Lake Constance, about 1300, died in Ulm, Jan. 25, 1365. He was educated in a Dominican convent at Constance, and at Cologne under the mystic Eckhart. After his mother's death he adopted her family name in his 18th year, and led a life of penance at the Constance convent till 1340, when he became an itinerant preacher of great influence, especially among women. His anniversary is celebrated by the Dominicans on March 2. Görres, who translated his autobiography, regarded him as among the most fascinating writers of his class, and his *Horologium Sapientiæ Æternæ* (1480) ranked in the middle ages next to the "Imitation of Christ." His works, which were written in Latin, have been often reprinted and translated into several languages (modern German by Diepenbrock, Ratisbon, 1829 and 1838). A new edition of his *Briefe*, by Prega, appeared in 1867.

**SUSQUEHANNA**, a river of New York, Pennsylvania, and Maryland, having its source in Otsego lake, Otsego co., N. Y. It flows generally S. W. to the Pennsylvania line in Broome co., receiving the Unadilla and several smaller tributaries; near the Pennsylvania boundary it flows around the base of a spur of the Alleghanies to Binghamton, forming what is called the "Great Bend;" after receiving the Chenango at Binghamton, its course is W. by S. till it again reaches the Pennsylvania line, where it takes a S. E. direction to Pittston, Luzerne co., receiving the Tioga and numerous small tributaries in its course; at Pittston it turns sharply S. W., passes Wilkesbarre, and receives near Sunbury the large affluent known as the West branch of the Susquehanna, which is more than 200 m. long, rising above Clearfield, and passing that town, Lock Haven, and Williamsport; then turning southward, it receives the Juniata 14 m. above Harrisburg, and flowing thence S. E. enters the Chesapeake bay at Havre de Grace. Its length is a little more than 400 m. from Otsego lake to the bay, and from the junction of the two branches 153 m. The river is generally shallow, and its course much broken by rapids; in the spring, during flood, rafts and strong boats float down from Binghamton, but at other times it is not navigable. Immense quantities of timber are transported upon it. Canals have been constructed along its banks, on the main stream for 125 m., and on the West branch for 124 m. Its waters abound with fish. The lower waters of the Susquehanna are famous for a great abundance of ducks and other wild fowl.

**SUSQUEHANNA**, a N. E. county of Pennsylvania, bordering on New York, and drained by tributaries of the Susquehanna river, a portion of which lies in the N. part of the county; area, 800 sq. m.; pop. in 1870, 37,523. The surface is very hilly, and the soil fertile and

well adapted to grazing. Timber is abundant, and the export trade in pine lumber is very extensive. It is traversed by several railroads. The chief productions in 1870 were 40,522 bushes of wheat, 31,117 of rye, 311,218 of Indian corn, 628,061 of oats, 177,864 of buckwheat, 341,717 of potatoes, 98,459 tons of hay, 108,584 lbs. of wool, 2,580,649 of butter, and 35,560 of honey. There were 8,282 horses, 24,533 milch cows, 20,023 other cattle, 35,700 sheep, and 8,806 swine; 3 manufactories of agricultural implements, 32 of carriages and wagons, 10 of furniture, 4 of iron castings, 18 tanneries, 6 flour mills, 52 saw mills, and 5 woollen mills. Capital, Montrose.

**SUSQUEHANNAS.** See CONESTOGAS.

**SUSSEX. I.** A N. county of New Jersey, bordering on New York and Pennsylvania, bounded N. W. by the Delaware river, and drained by the Flatkill, Paulinskill, Wallkill, and Pequest; area, 600 sq. m.; pop. in 1870, 23,168. The Blue mountains traverse the W. and the Hamburg and Wawayanda mountains the E. part, and the remainder of the surface is very hilly; the soil is very fertile. The Hopatcong lake is in the S. E. part, and supplies the summit level of the Morris canal; and there are several other small lakes. The Sussex railroad passes through it. Franklinite, iron ore, red oxide of zinc, and other minerals are found. The chief productions in 1870 were 64,532 bushels of wheat, 105,306 of rye, 422,776 of Indian corn, 268,477 of oats, 72,870 of buckwheat, 81,006 of potatoes, 40,335 tons of hay, 11,959 lbs. of wool, and 1,455,788 of butter. There were 4,230 horses, 17,376 milch cows, 5,338 other cattle, 3,976 sheep, and 14,414 swine; 8 manufactories of cheese, 1 of pig iron, 3 of castings, 5 of tanned and 5 of curried leather, 18 flour and 7 saw mills, and 6 distilleries. Capital, Newton. **II.** A S. county of Delaware, bordering on Maryland, Delaware bay, and the Atlantic, and drained by affluents of the Nanticoke and Pocomoke rivers and other streams; area, about 1,000 sq. m.; pop. in 1870, 31,696, of whom 5,438 were colored. The surface is almost level, and the soil fertile. It is intersected by the Delaware division of the Philadelphia, Wilmington, and Baltimore railroad, and the Junction and Breakwater railroad. The chief productions in 1870 were 69,239 bushels of wheat, 1,122,693 of Indian corn, 55,779 of oats, 87,300 of Irish and 53,390 of sweet potatoes, 3,161 tons of hay, 25,566 lbs. of tobacco, 185,005 of butter, 23,517 of honey, and 32,347 gallons of sorghum molasses. There were 4,074 horses, 1,265 mules and asses, 6,127 milch cows, 4,250 working oxen, 6,968 other cattle, 12,213 sheep, and 18,409 swine; 1 woollen mill, 5 flour mills, and 20 saw mills. Capital, Georgetown. **III.** A S. E. county of Virginia, bounded N. E. by Blackwater river and intersected by the Nottoway; area, 400 sq. m.; pop. in 1870, 7,885, of whom 4,923 were colored. The surface is hilly and the soil fertile. It is intersected by the Atlantic, Mississippi, and Ohio, and the Richmond, Fredericksburg, and Potomac railroads. The chief productions in 1870 were 118,305 bushels of Indian corn, 21,357 of oats, 7,223 of Irish and 9,818 of sweet potatoes, 16,110 lbs. of tobacco, 1,833 of wool, and 21,528 of butter. There were 546 horses, 876 milch cows, 1,682 other cattle, 1,352 sheep, and 5,731 swine. Capital, Sussex Court House.

**SUSSEX,** a S. E. county of England, bordering on Surrey, Kent, the English channel, and Hampshire; area, 1,464 sq. m.; pop. in 1871, 417,407. The coast line is not much broken, the most remarkable projection being Beachy Head, 564 ft. above the sea. A range of chalk hills, called the North Downs, crosses the N. E. part of the county; and the South Downs, with an average height of 500 ft. and from 4 to 6 m. broad, run through its entire length nearly parallel to the coast. The principal rivers are the Arun, Adur, and Ouse. The county is purely agricultural, and wheat and hops are the chief products. The downs are principally used for pasturage, and are famous for their mutton. Sussex is remarkably rich in antiquities. It is divided into East and West Sussex, and has two county towns, Chichester and Lewes; the other towns of greatest importance are Brighton, Hastings, New Shoreham, Rye, Arundel, and Newhaven.

**SUTHERLAND,** a N. county of Scotland, bordering on the Pentland frith, Caithness, the North sea, Ross-shire, and the Minch; area, 1,886 sq. m.; pop. in 1871, 24,317. Several small islands which lie off the N. and W. coasts are included in the county. On these sides the coasts are generally high and bold, and are indented by numerous arms of the sea; but that on the east is flat with a low sandy beach. The interior is mountainous, the highest summit being 3,280 ft. above the sea. The rivers are all small with short courses, but there are numerous lakes. The principal crops are oats, barley, and potatoes. Sheep farming is extensively carried on. Game, including deer, is abundant. Dornoch, the capital, is the only town. Great improvements were made by the dukes of Sutherland, proprietors of most of the county, aided by parliament.

**SUTHERLAND, George Granville Leveson Gower,** duke of, born Jan. 9, 1758, died July 19, 1833. He was a son of the marquis of Stafford, belonging to a family of historic distinction since the 14th century. He early entered the house of commons, and was ambassador in Paris from 1790 to 1799. In 1799 he was raised to the peerage as Baron Gower. In 1803 he inherited the vast estates of his uncle the duke of Bridgewater and of his father, which added to the Gower domain made him one of the richest men in the world. He extended his uncle's great picture gallery, and promoted the fine arts. He was created a duke Jan. 28, 1833. The Bridgewater estates passed to his second son Francis, afterward earl of Ellesmere, and the other property to the elder son,

George Granville Sutherland Leveson Gower (1786–1861), the second duke. The wife of the latter, Harriet Elizabeth Georgiana (born May 21, 1806, died Oct. 27, 1868), a daughter of the earl of Carlisle, and the queen's mistress of the robes for nearly 20 years, was celebrated for her beauty and accomplishments, and promoted anti-slavery and other philanthropical movements. The present and third duke is Sir George Granville William Sutherland Leveson Gower, born Dec. 19, 1828.

**SUTLEJ,** the most easterly of the five rivers of the Punjaub, in British India. It rises in Thibet N. of the Himalaya mountains, about lat. 31° N., lon. 82° E., flowing N. W. out of Lake Manasarowar, and in the early part of its course is joined by numerous tributaries. After a course of about 200 m. it turns W., and in about lat. 31° 10′, lon. 75° 4′, 550 m. from its source, it unites with the Beas, and the river thence flows S. W. and is called the Ghara until its junction with the Chenaub, 300 m. below, when the united stream takes the name of Punjnud, and joins the Indus after a course of about 50 m., in lat. 28° 58′, lon. 70° 23′. The upper Sutlej is supposed to be the Hesudrus and the lower the Hyphasis of the ancients. In the upper part of its course the Sutlej is an impetuous torrent, and the scenery magnificent. In the Punjaub plain it is from 7 to 30 ft. deep, and from 250 to 500 and 700 yards wide.

**SUTTEE** (Sans. *sati*, from *sat*, pure), properly, a chaste and virtuous wife, but commonly used to designate the self-immolation of a widow by burning herself with the dead body of her husband. The practice has existed for many centuries, not only in India but in other Asiatic countries. Diodorus Siculus gives an instance which occurred in the army of Eumenes more than 300 years B. C., and in India it is certainly of great antiquity, though the period of its origin is unknown. It was more prevalent there than elsewhere, from the belief encouraged by the Brahmans, and professedly derived from their most sacred books, that it conferred the highest merit not only on the widow herself, but on her dead husband. It was asserted by the Brahmanical writers that every woman who thus burned herself should remain in a region of joy with her husband 35,000,000 years, while otherwise she would have no place in paradise. The prevalence of the practice is to be attributed to belief in this view, rather than to any other influence. A careful study of the Vedas and the Institutes of Manu has shown, however, that these works not only do not command suttee, but impliedly prohibit the practice. Certain passages of the Vedas supposed to relate to it have been the subject of animated controversy among Anglo-Indian scholars. The practice prevailed long after the East India company came into power. The Mohammedan emperor Akbar prohibited it in the 16th century, but without much effect. In the first quarter of the present century several unavailing attempts to repress it were made by the company, and in the 12 years between 1815 and 1826 there were 7,154 cases of suttee officially reported in Bengal alone. In 1829 Lord William Bentinck, governor general, enacted a law declaring all aid, assistance, or participation in any act of suttee to be murder, and punishable as such. This measure created much excitement at first in Bengal, the Brahmans denouncing it with great violence as an interference with their religion, and even sending an agent to England with a large sum of money to procure its repeal; but it was rigidly adhered to, and the excitement soon subsided. In 1847, during Lord Hardinge's administration, the prohibitory edict was extended to the native states in subsidiary alliance with the government of India, and the practice is believed now to be extinct.—The mode of performing suttee was much the same throughout India, varying only according to the rank of the parties or the customs of each province. The widow, seating herself by the side of her husband's body, had the sides of her feet painted red, and then bathed herself and dressed in her finest clothes. Meantime a drum was beaten through the adjacent villages. A large company having assembled, a hole was dug in the ground, and a bed formed of green boughs, on which was reared the funeral pile of dry fagots, hemp, clarified butter, and other combustibles. The widow then gave her ornaments to her friends, painted her forehead, tied red cotton round her wrists, put two new combs in her hair, and, when the body of her husband was placed upon the pile, walked around it seven times, scattering parched rice and cowries, and finally ascended the pile, to which she was secured with ropes. The eldest son or the head man of the village usually lighted the pile. In Orissa the pyre was below the level of the ground, and the widow threw herself down upon it. The practice of suttee never prevailed S. of the Kistnah.

**SUTTER,** a central county of California, comprising the delta between the Sacramento and Feather rivers; area, 576 sq. m.; pop. in 1870, 5,030, of whom 208 were Chinese. It consists chiefly of rich bottom lands, almost the only inequality of surface being the Sutter buttes, an isolated group of three peaks in the north. There is little timber. The chief productions in 1870 were 673,749 bushels of wheat, 26,513 of Indian corn, 452,911 of barley, 14,630 gallons of wine, 126,657 lbs. of wool, 117,875 of butter, and 14,100 tons of hay. There were 4,754 horses, 3,623 milch cows, 4,476 other cattle, 35,078 sheep, and 10,690 swine. Capital, Yuba City.

**SUTTER, John Augustus** (originally SUTER), an American pioneer, born at Kandern, Baden, Feb. 15, 1803. He graduated at Bern, Switzerland, as a military officer, and in 1834 emigrated to America, where he became known as a Swiss. At Santa Fé he carried on for

some time a profitable trade with Indians and trappers, whose accounts of California prompted him in 1838 to cross the Rocky mountains; he went to Fort Vancouver and to the Sandwich islands, and thence to Alaska and along the coast of the Pacific, and on July 2, 1839, was stranded in the bay of Yerba Buena (now San Francisco). Penetrating into the interior amid great difficulties, he founded in the same year the earliest white settlement on the site of Sacramento, received a considerable grant of land, and in 1841 built a fort, calling it New Helvetia, which was afterward the first settlement reached by overland emigrants to California. The Mexican authorities appointed him governor of the northern frontier country; and subsequently under the American authorities he was justice of the peace (*alcalde*) and Indian agent. He acquired great influence and wealth, but was ruined in 1848, when gold was first discovered (February) on his property near Coloma, El Dorado co. His laborers deserted him, and his lands were overrun by the gold diggers. He never recovered them, though repeatedly advancing his claims, and has not received any indemnity excepting an annual allowance of $3,000 from the state of California. Since 1873 he has resided at Litiz, Lancaster co., Pa.

**SUTTON, Amos**, an English missionary, born at Sevenoaks, Kent, in 1798, died in Cuttack, India, Aug. 17, 1854. He was ordained as a missionary at Derby in 1824, and sent to Orissa, India, where he labored 30 years, visiting England and America once. He translated the Scriptures into Oriya, compiled an Oriya dictionary, grammar, and lesson book, wrote tracts, and translated many English works. In English he published "The Family Chaplain" (2 vols., Calcutta, 1831–'2), "Narrative of the Mission to Orissa," "Orissa and its Evangelization" (Derby, Eng., and Boston, 1850), "Hymn Book for Mission Congregations," and "Guide to the Saviour."

**SUVAROFF**, properly **Suvoroff, Alexei Vasilievitch**, count, and Prince Italiski, a Russian soldier, born Nov. 24, 1729, died in St. Petersburg, May 17, 1800. He entered the army at a very early age, served in the seven years' war, and commanded with success in Poland against the confederates of Bar (1768–'72), and subsequently against the Turks, the khan of the Crimea, and the Nogai Tartars, obtaining the rank of general-in-chief in 1783. In the campaign of 1787 against the Turks he raised the siege of Kinburn and was wounded, achieved another victory at Fokshani (July 21, 1789) together with the Austrians, and on Sept. 22 routed the main Turkish army on the banks of the Rimnik, for which he received the title of count, and the surname Rimnikski. After repeated repulses he stormed Ismail in 1790, losing 20,000 men, massacred the Turkish garrison of 30,000 troops, and nearly reduced the town to ashes. He was next governor of Yekaterinoslav, Taurida, and the conquered territories on the Dniester. In 1794 he defeated Kosciuszko jointly with Fersen (Oct. 10), and carried Praga, a suburb of Warsaw, by assault (Nov. 3), deluging it with blood. The news of this event he communicated to the empress in the following despatch: "Hurrah! Praga! Suvaroff;" and in reply the empress promoted him in these words: "Bravo! field marshal! Catharine." The caprice of Paul I. drove him from the service in September, 1798; but he was soon reinstated at the request of the emperor Francis of Germany, and in 1799 placed at the head of the united Austrian and Russian armies in Italy. He achieved many brilliant victories over the French, at Cassano, on the Trebbia, and at Novi, for which he was made Prince Italiski. He crossed the Alps to join Korsakoff, at the moment when Masséna's decisive victory over the latter at Zürich (Sept. 25, 1799) entirely changed the military situation, and he was recalled to Russia with the rank of generalissimo. An ovation prepared for him at St. Petersburg was countermanded by a caprice of the czar, and this undeserved mortification gave the death-blow to Suvaroff's shattered health. His autobiography has been published under the title of *Vie de Souvoroff tracée par lui-même, ou collection de ses lettres et de ses écrits*, edited by Glinka (2 vols., Moscow, 1819). One of the best biographies of him is by Polevoi (German ed., Mitau, 1853).

**SUWALKI. I.** A W. government of Poland, bordering on Lomza, Prussia, and the Lithuanian governments of Kovno, Wilna, and Grodno; area, 4,846 sq. m.; pop. in 1870, 524,489. It is level, well wooded, and drained by the Niemen, which constitutes its E. and N. frontier. The principal towns are Suwalki, Augustowo, and Kalvarya. **II.** A town, capital of the government, 150 m. N. E. of Warsaw; pop. in 1867, 16,896, including about 6,000 Jews. It was founded by King Sigismund Augustus, and has been much improved. It contains many brandy distilleries, and the trade is active, especially in horses and cattle during the periodical fairs.

**SUWANNEE**, or **Suwanee**, a N. county of Florida, bounded N., W., and S. W. by the Suwannee river; area, 790 sq. m.; pop. in 1870, 3,556, of whom 1,435 were colored. The surface is undulating, and the soil tolerably fertile. There are two or three small lakes and several swamps. The county is traversed by the Jackson, Pensacola, and Mobile railroad, and its branch from Live Oak to Lawton, Ga. The chief productions in 1870 were 50,934 bushels of Indian corn, 19,404 of oats, 17,670 of sweet potatoes, 10,741 of peas and beans, 511 bales of cotton, 61 hogsheads of sugar, and 17,427 gallons of molasses. There were 1,875 milch cows, 2,156 other cattle, 369 sheep, and 3,946 swine. Capital, Houston.

**SVEABORG**, the principal fortress of Finland, Russia, on the gulf of Finland, in the province and 3 m. S. E. of the town of Helsingfors, the

approaches to which it defends, and under its municipal authority; pop. about 4,000. It is built upon seven granitic islands forming an ellipse, all of them strongly fortified, and connected either by causeways or bridges of boats. The principal fort is on Vargö island, on the south, and comprises a strong castle and barracks, and magazines excavated in the rock. The total number of cannon is 2,000, but it generally mounts 800; and the usual garrison of the fortress varies from 6,000 to 8,000 men, though the casemates have accommodations for 12,000. The harbor within, to which there is but one entrance, has room for 70 ships of the line. The fortress was erected between 1749 and 1758 by Count Ehrenswerd, field marshal of Sweden (who is buried within it), as a defence against Russia. In 1808 it was besieged by the Russians, and after two months the Swedish commandant and admiral Cronstedt, though amply supplied with the means of defence, capitulated (April 7). Left in the possession of the conquerors by the peace of Sept. 17, 1809, it was called the "Gibraltar of the North," and has since been regarded as the strongest fortress of Russia on the Baltic. In August, 1855, it was severely but unsuccessfully bombarded by the allied fleet.

**SVERTCHKOFF, Nikolai,** a Russian artist, born in St. Petersburg in 1818. He spent several years in Paris, and in 1852 became a member of the academy of St. Petersburg, and in 1855 a professor there. He excels in painting horses, costumes, and figures, and also as a sculptor. His principal works include "The Czar Alexander reviewing his Troops," "A Russian Team of three Horses," "A Russian Horse Market," and "A Relay of Post Horses."

**SWABIA, or Suabia** (Ger. *Schwaben*), a duchy of the German empire during its earlier period, and subsequently one of its ten great circles or divisions. The circle was bounded N. by the Palatinate of the Rhine and Franconia, E. by Bavaria, S. by Switzerland, and W. by France, the Rhine flowing on the borders of the two latter. It had an area of 13,000 sq. m., and was conterminous with the present kingdom of Würtemberg, the S. part of Baden, and the district of Swabia and Neuburg in Bavaria. It is one of the most beautiful and fertile tracts in Germany, and is traversed by the Danube from S. W. to N. E., and diversified by the mountain scenery of the Black Forest on the west and the Alps on the south. It was originally called Alemannia, and received the name of Swabia (from the Suevi, who inhabited parts of it) when the Alemanni were conquered by Clovis in 496. St. Columbanus introduced Christianity in the 7th century. Toward the end of the 11th century it was in a very flourishing condition, and in 1080 the emperor Henry IV. made the duchy of Swabia hereditary in the family of Frederick of Hohenstaufen. It subsequently became one of the most powerful and most civilized countries of Germany. In the Italian wars the reigning house of Swabia stood at the head of the Ghibelline party, and when Conradin was executed at Naples in 1268 the line became extinct. (See HOHENSTAUFEN.) The various cities, prelates, and counts then made themselves independent, and since that time Swabia has not formed a separate state. Various confederacies, however, were formed at different periods, known in history under the name of Swabian leagues. The principal of these was the "great Swabian league" of 1488. The Swabian circle was definitely organized in 1563.

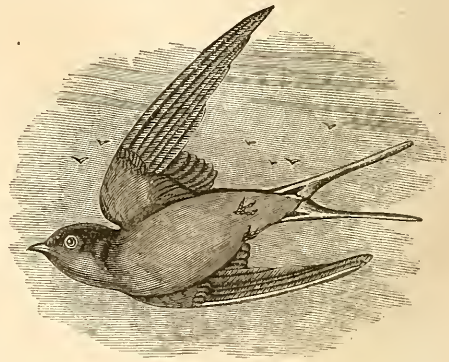
**SWAIN,** a S. W. county of North Carolina, separated from Tennessee on the north by the Great Smoky mountains; area, about 500 sq. m. It has been formed since the census of 1870 from Jackson co. The surface is generally elevated and mountainous; the soil is good and the county well adapted to stock raising. Capital, Charleston.

**SWAIN, Charles,** an English poet, born in Manchester in 1803, died near there, Sept. 22, 1874. He learned the business of dyeing, but at the age of 30 became an engraver. In 1828 he published "Metrical Essays," followed by "Beauties of the Mind" (1831) and "Dryburgh Abbey" (1832), an elegy on Sir Walter Scott. His subsequent publications comprise "A Memoir of Henry Liversedge" (1835); "Rhymes for Childhood" (1846); "Dramatic Chapters, Poems, and Songs" (1847); "English Melodies" (1849); "Letters from Laura d'Auverne" (1853); and "Art and Fashion" (1863). Swain was known as the "Manchester poet." A collection of his poems has appeared in the United States (Boston, 1858; new ed., 1872).

**SWAINSON, William,** an English naturalist, born in Liverpool, Oct. 8, 1789. He served in the Mediterranean in the army commissariat department from 1807 to 1815, then travelled in South America with Koster, the German naturalist, and on his return settled in London. In 1820 he commenced the publication of "Zoölogical Illustrations, or original Figures and Descriptions of new, rare, or interesting Animals," since republished in 6 vols. 8vo; and in 1821 of "Exotic Conchology" (4to; new ed., edited by S. Hawley, 1841). He has also produced a "Naturalist's Guide for collecting and preserving all Subjects of Natural History and Botany," &c. (1822); 12 volumes on natural history in Lardner's "Cabinet Cyclopædia;" two volumes on the "Birds of Western Africa" and one on the "Fly Catchers," in Jardine's "Naturalist's Library" (1837–'8); "A Treatise on Malacology, or the Natural Classification of Shells and Shell Fish" (1840); and a series of "Ornithological Drawings," being selections of Brazilian and Mexican birds (1834–'41). He assisted Sir John Richardson in the preparation of that part of his "Fauna Boreali-Americana" which relates to North American birds, and in connection with Mr. Shuckard prepared in 1840 "The History and Natural Arrangement of Insects." In 1841 he emigrated to New Zealand, and since his residence there he has published several works on

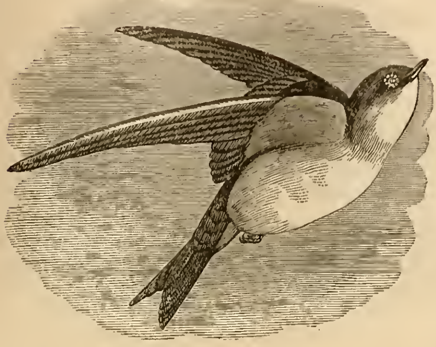
its social and political condition, and on the natural history of that colony and Tasmania.

**SWALLOW**, the general name of the diurnal fissirostral birds of the family *hirundinidæ*, not including the swifts, many of which are called swallows. (See SWIFT.) The bill is short and weak, very broad at the base and suddenly compressed to the tip; the wings long, narrow, and acute; primaries nine or ten, the first the longest; tail more or less forked; tarsi very short and weak, generally naked, and covered with scales; toes usually long and slender, with the claws moderate, curved, and sharp; the gape very wide and usually provided with short bristles. The typical genus *hirundo* (Linn.), having more than 50 species, embraces several well known, elegant swallows both in America and the old world, remarkable for their great powers of flight. Their food consists of insects, which they take on the wing, usually in the neighborhood of water, with remarkable skill and grace; they drink on the wing, sweeping along the surface of the water, and often wash themselves by a sudden plunge. They fly at the rate of a mile a minute in their ordinary evolutions, but are rather awkward on the ground from the length of the wings and the shortness of the legs; they live more on the wing than any other birds, even feeding their young in the air; their sight is very acute; they fly low in damp weather, where the insects are most abundant, and are thence supposed to foretell rain. They are most numerous in the tropics, migrating to and from temperate regions; in Great Britain they make their appearance from Africa, where they spend the winter, from the beginning to the middle of April, and depart toward the end of October, crossing the channel singly or in small parties; they often alight on vessels, and sometimes fall into the sea. In the United States they arrive about a month later and depart several weeks earlier. Most species prefer the neighborhood of man, building their nests in society in his dwellings and buildings; they form attachments to places, returning year after year to the same nests; they are docile and have been partially domesticated; a single bird probably collects about 1,000 insects in the course of a day. The nests are generally made of clay or mud mixed with straw and grass, of various forms, and attached externally to some building; many species breed in holes in sand banks, at the end of which is the nest of grasses and feathers; the eggs are five or six.—The best known species in the old world is the chimney or house swallow (*H. rustica*, Linn.); it is 6½ in. long, bluish black above, with a band on the chest, and the forehead, eyebrows, and throat, ruddy; lower parts rufous white, with a white spot on the inner web of each tail feather except the two innermost; the tail is very long and forked. As its name imports, it frequently builds its nest in chimneys a few feet from the top; it also nests in old walls and shafts of mines, and among the rafters of barns and sheds; the nest is cup-shaped, made of earth and straw and lined with feathers; the eggs are white, spotted with ash and red. The parents are very attentive to the young, and brave in their defence; they have two broods in a season, the second sometimes left to perish, not being able to quit the nest at the period of migration; the males are sweet singers, and very courageous. The analogue of this species in America is not the one commonly called chimney swallow with us (which is a swift), but the barn swallow (*H. horreorum*, Barton); it is about 7 in. long and 13 in. in alar extent, glossy steel-blue above, with concealed white in middle of back; it much resembles its European congener, though it has the pectoral collar interrupted in the middle, while in *H. rustica* it continues across. It inhabits North America from the Atlantic to the Pacific, appearing in the southern states from the middle of February to March 1, a few at a time, reaching New England in mild seasons by the middle of May. It is gentle and easily tamed. The nest is made of mud or moist earth mixed with grasses, and is attached to the beams and rafters of barns and outbuildings; it is generally about 8 in. long, 6 in. in the greatest diameter, and from beam to outside of shell 6½ to 4 in., weighing often more than 2 lbs.; the eggs are four to six, small and long, white with a few spots of reddish brown; incubation lasts 13 days, both sexes assisting, and both occupying the nest at night until the young are hatched. This species collects in large flocks in midsummer on barns and sheds, telegraph wires, &c., chirping almost continually, and making short sallies in search of insects. They start for the south by the end of August or first of September, early on some fair morning; they do not fly high, and follow the shore or the course of rivers.—The cliff or fulvous swallow (*H.* [*petrochelidon*] *lunifrons*, Say) is about 5 in. long and 12½ in. in alar extent; the crown and back are steel-blue, separated more or less broadly by a grayish collar; the chin, throat, and sides of head dark chestnut; breast grayish brown;



Barn Swallow (Hirundo horreorum).

belly white; steel-blue spot on throat; rump light chestnut, and forehead brownish white; tail slightly notched. It is found throughout North America from ocean to ocean; it



White-bellied Swallow (Hirundo bicolor).

is called republican swallow by Audubon, in allusion to the habit of associating to make their nests and rear the young. The nest is built under eaves and cornices, where it is partly sheltered from the rain; it is made of clay and sand, the entrance near the top, shaped like an earthen retort with the neck broken off; it is lined with straw and grass; the eggs are white with dusky spots; the nest is bravely defended by the parents. The white-bellied swallow or American house martin (*H. bicolor*, Vieill.) is $6\frac{1}{4}$ in. long and $12\frac{1}{2}$ in. in alar extent, of a glossy metallic green above and white below; it comes earlier in the spring than the others, but is not so common; the nest is made in a hollow tree, lined with

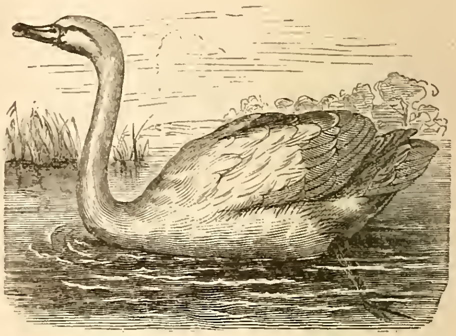
Sand Swallow (Cotyle riparia).

grass and feathers, and the eggs are white with a bluish tinge; it is as widely distributed as the others in North America, and some time before migrating southward gets very fat on myrtle berries (*myrica cerifera*). For the largest of the American swallows, see MARTIN.—The bank, sand, or river swallow belongs to the genus *cotyle* (Boie); it is the *C. riparia* (Boie), and the smallest of the American species, being $4\frac{3}{4}$ in. long and $10\frac{1}{2}$ in. in alar extent. The bill is very flat, and extremely wide at base, gradually narrowing toward the tip; nostrils prominent and rounded; tail moderate, nearly even or very slightly forked; tarsi rather long, with a tuft of feathers near the toes behind. It is grayish brown above, sometimes approaching sooty, with paler margins; below pure white, with a band across the breast and sides like the back. It is generally distributed over America and Europe, wherever there is a sandy pit or river bank; it is the earliest to arrive in the spring, and less familiar than the other species; it hollows out a tubular gallery in the sand banks, often more than 3 ft. in length, at the end of which is a larger excavation for the nest; it is called sand or bank martin in Europe. There is no appreciable difference between the European and American birds.

**SWAMMERDAM, Johannes,** a Dutch entomologist, born in Amsterdam in 1637, died about 1680. He studied medicine with his father and at the university of Leyden. He gave considerable attention to the natural history of insects, and made many dissections and microscopical examinations and a large collection of specimens. He obtained leave at Amsterdam to dissect the bodies of those who died in the hospital, and invented the mode for the preparation of hollow organs now usually employed in anatomy. He published a "General History of Insects" (1669), "The Natural History of Bees" (1673), a "History of the Ephemeras" (1675), and other works. His entomological collection was divided at his death and sold in small portions. Boerhaave edited his works and wrote his life. An English translation of his entomological works by T. Floyd was published in 1758.

**SWAN,** a web-footed bird of the duck family, and the type of the subfamily *cygninæ*, embracing some of the largest and most graceful of aquatic birds. The bill and feet are much like those of the ducks, the former being stout, of nearly equal width throughout, and with a comparatively small nail; the neck very long, and the legs short; wings long and powerful, second and third quills equal and longest; tail short and rounded; eyes small and near the bill. They perform long migrations, flying in single files uniting at an acute angle; the diet consists of grass, roots, and seeds, in search of which they submerge the head only, keeping it under water three to five minutes at a time; they also devour aquatic worms and insects, young frogs, and probably small fish; the intestines are long, as in the vegetable feeders; they are gregarious at all seasons, awkward on land, but rapid and high fliers; they are remarkably careful to keep their plumage, which

is generally white, free from dirt. The nest is bulky, of grass and coarse materials, placed on the ground among the rushes and near the water; it is sometimes raised a foot or more to avoid inundations; the male guards the nest, assists the female in the care of the young, and boldly defends them even against predaceous animals and man; the eggs are five to eight, and incubation lasts six weeks.—In the typical genus *cygnus* (Linn.) the bill is longer than the head, the base covered by a soft skin extending to the anterior half of the eyes, and the nostrils in the middle portion; lower part of tibia bare; tarsus much shorter than the foot, compressed and scaly; webs full; hind toe small, much elevated, with a narrow lobe; tail of 20 to 24 feathers, rounded or wedge-shaped; sexes similarly colored, but the females the smaller. Wagler has divided the old genus *cygnus* into two, *cygnus* and *olor*, according as there is or is not a swollen fleshy tubercle at the base of the bill; in the former also the lamellæ of the edges of the bill are visibly projecting, and in the latter not; in the former belongs the tame swan of Europe, and in the latter the wild swan and both of the North American species. The European wild or whooping swan (*C. ferus*, Ray) is $4\frac{1}{2}$ to $4\frac{3}{4}$ ft. long, white, with the head and neck tinged with yellowish, and a black bill, yellowish at the base and without tubercle; it is a winter visitor in Great Britain, migrating northward in the spring to Lapland, Russia, Siberia, &c., where it breeds; the young are brownish gray. The male has a peculiar note resembling the word "hoop," repeated several times in succession, the intensity greatly increased by the convolutions of the windpipe, which, after penetrating the keel of the breast bone to its posterior portion, is bent forward again to the front of this bone before going to the lungs; this peculiarity is not found in the tame swan, which has a soft and plaintive voice. The swan is cruel and vindictive; the males fight savagely at pairing time, and the female with young attacks everything which approaches her nest; it can repel any bird, even the eagle, and in fighting the combatants try to drown one another by holding the rival's head under water, often with success. Though heavy fliers, they rise to a great height, uttering a loud, harsh, and trumpet-like note when sailing high in the air; when enraged or alarmed they can swim faster than a man can walk. This bird was sacred to Apollo, and was the bird of the Muses; it was fabulously celebrated for its melodious song, especially at the time of its death. The flesh is dark and tough. The European tame swan (*C. olor*, Gmel.) has a red bill, with black tip and sides, and a tubercle at the base; the trachea has no convolutions. It is generally distributed over Europe and America as an ornamental bird; it is large and handsome, a permanent resident in temperate Europe; in Great Britain from remote periods it has been protected by preservative laws; the male is called a cob and the female a pen; its life is said to extend to a century. The young have a gray plumage and a lead-colored bill. The flesh is said to have a flavor between that of the goose and the hare. The most prized are brought to the United States from Hamburg, and are generally what are called Polish swans (*C. immutabilis*, Yarr.), from the Baltic shores, noted for having white cygnets.—The American or whistling swan (*C. Americanus*, Sharpless) is 55 in. long and about 7 ft. in alar extent, with a bill of $4\frac{1}{2}$ in.; the bill is as long as the head, high at the base, the feathers on the forehead ending in a semicircular outline; the nostrils far forward; tail of 20 feathers; the adult is pure white with bill and legs black, and an orange or yellowish spot in front of the eye; young birds are brownish, especially on the head; they are five or six years in coming to maturity. This species is spread over the North American continent from the Atlantic to the Pacific; many are shot in winter and spring on the coasts of Virginia, Maryland, and Delaware; when they are feeding, one always acts as sentinel; they fly in an angle, each line in single file, the leading bird as he gets weary retiring to the rear. The nest is described as made of moss, peat, and sticks, 5 to 6 ft. long, $4\frac{3}{4}$ ft. wide, and 2 ft. high, with the cavity $1\frac{1}{2}$ ft. in diameter; the eggs are brownish white, clouded with darker. The trumpeter swan (*C. buccinator*, Rich.) is about 5 ft. long and 7 ft. in alar extent, with the bill $4\frac{1}{2}$ in.; bill longer than the head, the feathers on the forehead with a semi-elliptical outline; nostrils with the anterior extremity only as far forward as the middle of the commissure; tail with 24 feathers; the adults are pure white, the legs and bill entirely black, the latter without any red spot at base. It is found from the Mississippi valley to the Pacific, appearing on the lower Ohio about the end of October, and going south when the ice gets thick; it is very common in the fur countries, breeding as far north as lat. 61° N. The note is more sonorous than in the whistling swan; it is not so wary as the last named species;



European Tame Swan (Cygnus olor).

it is the principal source of the fine down so much prized for muffs and tippets.—A black swan, once considered as apocryphal as a white crow, inhabits Australia. The *chenopis atrata* (Wagl.), of that continent and Tasmania, is black except a few white primaries and a bright red bill; it is nearly as large as the common swan, and is now not unfrequently seen with it in the parks of Europe and the United States.

**SWAN RIVER.** See Western Australia.

**SWANSEA** (Welsh, *Abertawy*), a town of Glamorganshire, Wales, on the W. bank of the river Tawy, where it falls into the bay of Swansea, Bristol channel, 60 m. W. N. W. of Bristol; pop. in 1871, 51,702. It is much resorted to for sea bathing. There are extensive anthracite mines in the neighborhood, which, together with the convenience of the port, have made it the principal seat of the copper trade of Great Britain. Copper ore is brought hither for smelting from Cuba, North and South America, Australia, &c. There are also iron, tin plate, and zinc works, potteries, and ship yards. The port was entered in 1873 by 6,835 British vessels, tonnage 877,241, and 1,165 foreign vessels, tonnage 197,062. There were cleared 6,612 vessels, tonnage 859,619, of which 1,258 were foreign, tonnage 216,527. The exports in the same year were valued at £1,855,712. The exports of coal in the year ending with February, 1875, were 30,592 tons, and the coastwise shipments 17,874 tons. There are extensive docks; the first floating dock was built at Swansea in 1852. Large vessels can come close to the town at flood, but at ebb the harbor is nearly dry.

**SWEATING SICKNESS,** a disease which often prevailed extensively in Europe and Asia during the middle ages, and which still frequently appears in Turkey and other parts of Europe and Asia. The older descriptions of it are somewhat vague, but from the general symptoms it is doubtless the disease which has been accurately described by Rayer and others, and is now called miliary fever, sudatoria, and miliaria, and is defined as "an eruption of innumerable minute pimples with white summits, occurring in successive crops upon the skin of the trunk and extremities, preceded and accompanied with fever, oppression of respiration, and copious sweats of a rank, sour, fetid odor, peculiar to the disease. The base of the pimples and the skin around are red and irritable." Pathologists are not agreed as to its specific nature; some deny that a peculiar specific disease exists, as in smallpox or scarlatina. The fever which precedes the eruption is ushered in by intense chills, oppression of breathing, fainting, and pains in the head, loins, and limbs. In a few hours nausea and profuse sweating come on, but without relieving the other symptoms. The pulse is small and rapid, often hard and irregular. The tongue is coated with a foul yellow fur, and the bowels are constipated. From the 5th or 6th day to the 21st an itching sensation is felt in the mammary and epigastric regions and the inner surface of the arms, and the skin of those parts becomes red and rough, with numerous elevations about the size of common pin heads. In a short time the summits of these elevations become pearly white, the cuticle being elevated by a slightly opaque, sero-albuminous fluid. Several crops of elevations break out in succession for from three to seven days, followed by desquamation of the cuticle. In severe cases the eruption appears at the junction of the skin and mucous membrane, and is liable to become aphthous. Two forms are recognized, the mild and the malignant, the latter being accompanied by violent inflammation of some internal organ, and proving fatal sometimes in two or three days. The treatment consists in cooling drinks, bland diet, and frequent laving and sponging of the cutaneous surface.—The disease appeared in England in 1485, just after the battle of Bosworth, and disappeared suddenly at the beginning of the next year. It attacked people chiefly in the prime of life, and scarcely one per cent. recovered. It appeared again in the summer of 1506, bnt in a mild form. In July, 1517, it appeared in a very malignant form, sometimes terminating fatally in a few hours. It lasted for six months, and like the preceding epidemics was confined to England. In May, 1528, it again appeared in London. It lingered in the city till the next year, and was so fatal as to receive the name of "the great mortality." It finally extended over the northern half of the continent, and 2,000 persons fell victims to it in 21 days at Hamburg. In 1551 it made its last appearance in England, and continued six months.

**SWEDBERG, Jesper,** a Swedish clergyman, father of Emanuel Swedenborg, born at Fahlun, Aug. 28, 1653, died at Brunsbo, July 26, 1735. His father was a copper smelter named Daniel Isaksson. Swedberg took his name from a small family estate. He was educated at Upsal, and in 1685 was ordained a priest and appointed chaplain to the king's regiment of cavalry life guards. In 1690 he was made pastor of Vingaker, in 1692 professor of theology at Upsal, and soon after rector of the university. In 1691 he was one of a commission to revise the Swedish Bible, which work was completed in a year. In 1694 he published a psalm book, which was suppressed as pietistic. In 1702 Charles XII. made him bishop of Skara in West Gothland, in which office he remained till his death. In 1722 he produced the first Swedish grammar ever printed. About 1732 the Swedish congregations in London, Lisbon, and North America elected him their bishop.

**SWEDEN** (Swedish, *Sverige*), a kingdom of northern Europe, forming with Norway the Scandinavian peninsula, and lying between lat. 55° 20′ and 69° N., and lon. 11° 10′ and 24° 10′ E. It is bounded N. and W. by Norway, S. W. by the Skager Rack, the Cattegat, and the Sound, S. by the Baltic sea, E. by the Baltic

and the gulf of Bothnia, and N. E. by Finland. It is separated from Norway by the main chain of the Scandinavian system of mountains, along which a broad avenue cut in the forest, and having at certain intervals stone monuments, marks the line of division. This avenue is maintained with great care by the Norwegians, and its condition regularly reported to their *storthing* or legislature. The extreme length of Sweden is 970 m., and its general breadth about 200 m.—The coast line, about 1,400 m. in extent, is deeply indented by numerous *fiords* or gulfs. About 300 m. of the coast borders on the Skager Rack, Cattegat, and Sound; the remainder is washed by the Baltic and the gulf of Bothnia. The W. shore along the Skager Rack and Cattegat is rocky, but seldom elevated more than 30 or 40 ft. The S. shore as far as Sölvesborg in Blekinge is low and sandy; thence northward it is, with some exceptions, lined by precipitous cliffs about 50 ft. high as far as Calmar sound. Along the Sound the coast is again low and sandy, but N. of it rises into higher cliffs, and at the outlet of Lake Mælar presents bold headlands 100 ft. high. N. of the mouth of the Dal and as far as the strait of Quarken rocky and sandy shores alternate; and the upper part of the gulf of Bothnia is characterized by low sandy beaches. The entire coast N. of Calmar is lined with numerous rocky and sandy islets, which render access difficult in many places. Off of the län of Calmar, and separated from it by Calmar sound, is the island of Öland; and N. E. of this lies Gottland, the largest island of Sweden. The Aland group, off the län of Stockholm, belongs to Russia.—The mountain chain which forms the spine of the Scandinavian peninsula has a much larger portion of its most elevated surface in Norway than in Sweden. Its southern part, the Langfield chain, is wholly in Norway, while the Dovrefield and Kiölen chains form the boundary between the two countries, Sulitelma in lat. 67° and Sylfjell in lat. 63°, lie partly in each. The Norwegian side of these mountains is much more precipitous than the Swedish. In Sweden they form a plateau nearly 4,000 ft. high, from which occasional peaks rise to a greater height, but which in a breadth of 40 m. slopes gradually to an elevation of from 800 to 1,000 ft., and thence declines in hills of moderate elevation to the sea shore. S. of lat. 59° the country is very level, and the great plain of Scania, the most fertile tract of the peninsula, occupies a considerable portion of the southern extremity. The northern part of Sweden is rocky, with bleak, barren, snow-clad hills, and a stunted vegetation of birch, fir, and small pines, in the higher lands intermingled with dreary lakes and swamps. The great forest region lies S. of lat. 64°, where the surface is less elevated. Further S. it is more level, and the woods give place to cultivated fields.—Sweden abounds in beautiful lakes, which cover more than 14,000 sq. m. of its surface. Lake Wener has an area of about 2,000 sq. m., and, excepting Ladoga and Onega in Russia, is the largest lake in Europe. Its principal affluent is the Klar, which enters it from the north, and its waters are carried into the Cattegat by the Götha. At the Trolhätta falls on the latter, the river descends by rapids 108 ft. in 5 m. Lake Wetter is 80 m. long and has an area of 715 sq. m. Its surface is about 300 ft. above the sea, and in one part it is more than 400 ft. deep. It has many small affluents. The river Motala carries its waters through several smaller lakes into the Baltic. The Mælar lake, about 75 m. long, is a series of lakes connected by channels and having many branches. It contains more than 1,200 islands, most of which are of great beauty. Other principal lakes are Hjelmar, connected with the Mælar, Siljan, Stor, Stor Uman, Horn Afvan, Stora Lulea, and Tornea, almost all in the north. None of the rivers of Sweden are navigable, excepting those which have been rendered so artificially. With the exception of the Klar and a few smaller streams on the W. coast and on the coast of the Baltic, nearly all of them have their source in the main mountain range and flow S. E. into the gulf of Bothnia. The largest is the Dal, which is formed by the junction near Fahlun of the East Dal and the West Dal, and enters the gulf of Bothnia near Gefle. At Elfkarleby, near its mouth, it forms a splendid cascade, which is surrounded by fine scenery. N. of this the principal rivers are the Ljusne, Indals, Angerman, Umea and its branch the Windel, Skelleftea, Pitea, Lulea, Ranea, Kalix, and Tornea. The last, with its branch the Muonio, forms the boundary line between Sweden and Russia. Most of these rivers have cataracts and rapids. The Angerman is 240 m. long, and is navigable for vessels of 600 tons 60 m. from its mouth.—The geological formations of Sweden are chiefly granites, gneiss, and metamorphic rocks. They compose most of the Scandinavian chain of mountains, and are in many places covered with Silurian strata, which sometimes are seen undisturbed from their original horizontal position. These are broken through and overflowed by trap; and the surface is generally covered with the drift formation and large bowlders. The metamorphic group abounds in metallic veins, which constitute a large portion of the wealth of the country. Among the metals produced are iron, copper, lead, zinc, silver, gold, nickel, cobalt, and manganese. The pyritiferous slates are largely worked for alum and copperas, and these, as well as the sulphurous gangues of the various ores, furnish unlimited supplies of sulphur. In 1872 there were produced 4,881 cwt. of alum, 1,914 cwt. of iron vitriol, 2,936 cwt. of copper vitriol, and 7,667 cwt. of sulphur. The most important iron mines are those at Dannemora and Osterby in the län of Upsal, Presberg in Wermland, Taberg in Jönköping, and in the läns of Örebro, Gefleborg,

Kopparberg, and Westmanland. Taberg is a mountain of magnetic ore 1,129 ft. high. At Gellwara, near the Lulea river, in Norrbotten, is also a mountain of nearly pure magnetic iron ore, with some specular ore. Swedish iron is not excelled by any in the world, and is largely used in the manufacture of steel. Nearly 500 iron mines were open in 1873; the total yield of rock iron ore was 18,170,000 cwt., and of bog iron ore 117,793 cwt. The principal copper mines are at Fahlun in Kopparberg, at Atvidaberg in Ostergottland, at Flögforss in Örebro, in Jämtland, and in Westmanland. Silver is mined in small quantities at Sala in Westmanland and in Örebro, and zinc near Askersund in Örebro and other places. In 1873 the yield of copper was about 5,000 cwt., of silver 16 cwt., of zinc 602,883 cwt., of nickel 24,420 cwt., and of manganese 6,713 cwt. Coal of inferior quality is found near Helsingborg in Malmö, and large veins of better quality have been discovered lately in other parts. The yield in 1873 was 2,406,486 cubic feet. Marble is quarried in Ostergottland, and at Elfdal in Kopparberg are the celebrated porphyry quarries, where many varieties of that stone are found. In 1872 14,734 mining licenses were issued in the kingdom. An interesting geological change in the coast line of Sweden is the gradual rising of the land along the gulf of Bothnia and the Baltic sea. This was first observed in the beginning of the 18th century by Celsius, who attributed it to the subsidence of the waters of the Baltic; but in 1807 Von Buch made a careful examination of the coast, and announced his conviction that "the whole country, from Frederikshald in Norway to Abo in Finland, and perhaps as far as St. Petersburg, is slowly and insensibly rising." According to later observations, the greatest rise is further N. at the top of the gulf of Bothnia, where it amounts to about 4½ ft. in a century; at Gefle, 90 m. N. of Stockholm, it is from 2 to 3 ft. in a century; at Stockholm it is scarcely 6 in.; and at Malmö the movement seems to be downward.—The soil is generally not very fertile, much of it being the result of the disintegration of primitive rocks, and containing a large proportion of silex. The productive soil constitutes about 53 per cent. of the entire area, the remainder being sand barrens, rocks, and heaths. Of the productive parts about 13 per cent. are arable, 5 per cent. meadow lands and pasturage, and 82 per cent. forests. The climate of the Scandinavian peninsula is generally milder than that of other countries in the same latitude. The average winter temperature in the more populous portions of the country is but little lower than that of the state of New York. At Stockholm, in lat. 59° 20′, the mean annual temperature is about 42°, that of winter 25° and of summer 62°; at Lund, lat. 55° 42′, the annual mean is 45°, that of winter 30° and of summer 62°; at Fahlun, lat. 60° 36′, the annual mean is 40°, that of winter 22° and that of summer 58·30°; and at the Russian frontier village Enontekis, lat. 68° 30′, and at an elevation of 1,440 ft., the annual mean is 27°, the winter temperature 2° and the summer 55°. In Swedish Lapland there are scarcely two months of summer. In Norrland, in nine weeks, hay will have been cut twice and the year's seeding and harvest completed. At Stockholm the longest day is 18½ hours and the shortest 5½ hours; at Tornea 22 hours is the longest; and at Enontekis the sun remains above the horizon about seven weeks.—The pine and fir forests of Sweden furnish a great abundance of timber, which is largely exported. In the middle province there are also considerable quantities of ash, linden, willow, maple, and the weeping birch, one of the most beautiful of northern forest trees. In the southern province the oak attains great size and beauty, and the beech and elm are common. With the exception of the cherry there are few fruit trees N. of the 60th parallel, and scarcely any trees grow N. of the 64th parallel. Barley is cultivated in all parts of Sweden, and rye, wheat, oats, beans, peas, and potatoes are successfully grown in the middle and southern provinces. Apples and pears grow in the southern districts, and cranberries and other berries in the northern. The gooseberry grows all over the country. Tobacco is raised in the vicinity of Stockholm. Root crops are largely cultivated. The agricultural crops in 1874 were as follows, in imperial bushels: wheat, 4,000,000; rye, 20,000,000; barley, 12,000,000; oats, 30,000,000; potatoes, 52,000,000. Large quantities are also raised of peas, beans, mixed grain, buckwheat, hemp, and hay. During the year ending Sept. 30, 1873, 11,852,049 bushels of cereals were exported from Sweden; and the total imports of grain, flour, and meal during the same time were 2,326,581 bushels. The crops of 1874 were below the average, and the importations of grain were larger than in 1873.—The fauna of Sweden is not so numerous as that of some of the other northern countries of Europe. The principal quadrupeds are the brown bear, wolf, lynx, fox, glutton, deer, reindeer, elk, marten, otter, beaver, sable, hare, and squirrel. Bears, elk, deer, and beavers are now scarce. Wild reindeer are sometimes met with in the northern provinces. Lemmings occasionally come down in droves from the Kiölen mountains and lay waste the country in their path. Among the indigenous birds are the eagle, eagle owl, falcon, hawk, swan, goose, eider duck and other species of wild ducks, gull, ptarmigan, capercailzie and other grouse, woodcock, blackcock, and snipe. The sheltered coasts of the Baltic and the gulf of Bothnia are the resort of immense flocks of sea fowl. The lakes, rivers, and seas abound with fish. Many of the rivers contain fine salmon, trout and grayling are caught in every mountain stream, and pike and perch abound. The turbot, cod, mackerel, ling, and herring are taken in considerable quantities, and lobsters, crabs, and

oysters are abundant. Great numbers of the *strömming*, a small fish about as large as a sprat, are caught in the gulfs of Bothnia and Finland, and cured. It is said that more than 80 kinds of salt and fresh water fish are sold in the markets of Gothenburg. The domestic animals are mostly small and of inferior quality, but efforts are making to improve the breeds, particularly of sheep. Fine animals are imported from foreign countries, and there are public breeding establishments. In 1870 there were in Sweden 1,966,500 horned cattle, 1,595,000 sheep, and about 428,500 horses.—The three great divisions of Sweden, Gothland (Sw. *Götaland*), Svealand, and Norrland, are subdivided into 24 läns or districts, the extent and population of which in 1874 were as follows:

| DIVISIONS. | Area, sq. m. | Population. | CAPITAL. |
|---|---|---|---|
| GOTHLAND. | | | |
| Malmö | 1,847 | 325,909 | Malmö. |

Gothland (the region originally inhabited by the Goths) lies S. of lat. 59°, and comprises also the islands of Öland and Gottland; Svealand, the original country of the Svenskar or Swedes, extends from Gothland northward to about lat. 60° 15′ at its eastern extremity, and lat. 62° 15′ at the western; and Norrland is the whole northern part up to the Norwegian frontier of Finland. In 1874 Sweden had 89 towns, only one of which, Stockholm, the capital, had more than 100,000 inhabitants (147,249). Of the others, Gothenburg had 61,599, Norrköping and Malmö from 25,000 to 30,000 each, and Carlscrona, Gefle, Upsal, Lund, and Jönköping from 12,000 to 18,000 each.—Besides the Swedes proper, the population of Sweden in 1870 included 6,611 Lapps, 27,079 Finns, and 12,015 foreigners; of the last, 2,856 were Germans, 2,795 Danes, 2,570 Norwegians, 2,018 Finlanders, 806 Russians, 355 English, 157 Americans, 122 French, and a few of other nationalities. Besides the members of the Lutheran church, to which nearly all the native population belong, there were in 1870 3,809 Baptists, Methodists, and Mormons, 1,836 Jews, 573 Roman Catholics, 30 Greek Catholics, and 190 of the Reformed church. The number of householders in 1870 was 1,017,323. The average number of marriages in every 10,000 inhabitants during the decade ending in 1870 was 65·44; the whole number of divorces during the same period was 1,301. The proportion of illegitimate births in the whole kingdom in 1873 was 11 per cent., and in Stockholm 38·15 per cent. In 1870 the number of paupers wholly supported at the public expense was 85,147, and the number of convicts in all the prisons was 5,951. Intemperance, which has heretofore prevailed so extensively as to mar the character of the people, has been checked by wise legislation, and crime has decreased; but the consumption of distilled spirits as drink is still large, in the proportion of about 2½ gallons a year to each inhabitant. Monday, as well as Sunday, is often spent by working men in dissipation, which has given rise to the phrase "free Monday." Like the other branches of the Scandinavian race, the Swedes are tall and of a sandy or florid complexion and powerful physique. As a nation they are enterprising, energetic, honest, and thrifty. More than half of the population belong to the peasantry or *bonde* class, who are gradually absorbing the landed property of the kingdom. They are mostly engaged in agriculture, and are industrious and prudent. The cottager or *torpar*, who hires his house and patch of ground, is below the peasant in social rank. The law formerly prescribed the costumes for the lower classes, but now all dress as they please. In Dalecarlia (the region on both sides of the Dal) the peasants of each parish have different and fanciful costumes. Wooden shoes or leather shoes with wooden soles are largely worn. Men, women, and children labor together in the fields; women do various kinds of outdoor work in the towns, such as the mixing of mortar and the tending of masons, and most of the drudgery in factories. By law no children under 12 years of age can be employed in a factory, and none under 18 can be required to work after dark. In 1873 more than 26,000 persons were employed in the mines and in mining industry. The class of burghers are members of the various mercantile guilds or are engaged in manufacturing. The nobility consists of about 1,600 families. They formerly possessed one fifth of the landed property of the kingdom, but many of them are now very poor, and their pride will not permit them to en-

gage in commercial or industrial pursuits. Although their political power as a distinct class was annulled by the reform of the constitution in 1866, they still hold the chief offices in the state, and in one of the guard regiments only noblemen are commissioned officers. There has of late been a large emigration from Sweden, chiefly to the United States, which in 1869 amounted to 39,069; but it decreased in 1870 to 29,003, in 1871 to 17,450, in 1872 to 15,915, and in 1873 to 13,580.—Sweden has made great progress in manufacturing industry within the past few years. While the number of distilleries, of which in 1835 there were 85,172 small and 670 large ones, had diminished in 1866 to 565, other branches of industry have greatly increased. The value of the goods produced in the registered manufactories of the country in 1830 was $3,500,000; in 1840, $5,700,000; in 1850, $10,900,000; in 1860, $18,500,000; in 1865, $20,300,000; and in 1870, $24,700,000. These sums are exclusive of the products of hand trades, which are estimated to be equal in value to the manufactures proper. The number of manufactories in 1830 was 1,857, in 1865 2,315, and in 1870 2,183. In 1870 the manufactories produced cloth valued at $2,300,000; other textile fabrics, $1,500,000; silk, $290,000; cotton spinning, $2,300,000; leather, $1,300,000; tobacco, $1,600,000; sugar, $3,500,000; metals, $2,100,000; and paper, $760,000.—The following table shows the value of the imports and exports for the five years ending with 1873:

| YEARS. | Imports. | Exports. |
|---|---|---|
| 1869 | $36,610,000 | $33,720,000 |
| 1870 | 37,970,000 | 40,870,000 |
| 1871 | 45,340,000 | 42,150,000 |
| 1872 | 58,090,000 | 53,550,000 |
| 1873 | 72,746,000 | 59,470,000 |

Partial returns for 1874 show a further relative increase in imports and a decrease in exports. The imports from the United States in 1873, direct and indirect, amounted to $7,476,878; the exports to the United States, $3,073,074. The chief imports of Sweden are textile fabrics, groceries, mineral ores and manufactured metals, ships, carriages, and machinery, bones and hides, yarn, thread, and spinning materials, wines and alcohol, colors and dyes, and coin. The chief exports are timber, metals, grain, cattle, provisions (animal), tallow and oil, and paper and paper goods. The direct imports from the United States are petroleum, resin, tallow, and agricultural machines and implements; indirect, cotton, pork, tobacco, sewing machines, and gold and silver bullion. The merchant marine of Sweden in 1872 numbered 3,878 vessels (including 498 steamers), of 426,000 aggregate tonnage.—Sweden has remarkable facilities for internal navigation through a series of lakes, rivers, and bays, connected by more than 300 m. of canals. These furnish direct water communication between the Baltic and the North sea, which is of great importance, as in case of war the Danes would command the channels through the Belts and the Sound. The importance of this connection was well understood in the 12th and 13th centuries, but Gustavus Vasa was the first to undertake it. Various sovereigns continued the work, and in 1823 the line was opened from Söderköping on the Baltic through Lakes Wetter and Wener. The canal from Lake Wener around Trollhätta falls, originally built in 1800, was next enlarged and rebuilt, and in 1855 the entire route was thrown open for steamers. It is in all 235 m. long, of which about 60 m. are across the lakes. Its most elevated point is Lake Wiken, between Wetter and Wener, where it is 299 ft. above the level of the sea; the descent is made by vessels on each side through 37 locks. Other canals connect the Mælar lake with Lakes Hjelmar and Barken, and with the Baltic. There are excellent roads all over the country, and in winter, when the canals and lakes are frozen and the ground is covered with snow for four or five months, communication is easily kept up with the interior by means of sledges. A network of railways is now in course of construction, to connect all the important districts of the kingdom, chiefly at the expense of the government. The state lines include the main or trunk lines, the principal of which are the western, from Stockholm to Gothenburg, and its branches; the southern, from Falköping on the western line to Malmö; the northwestern, from Laxa on the western line to the frontier of Norway; the eastern, from Kathrineholm on the western line to Norrköping; and the northern, connecting Stockholm with the principal cities of the north. In August, 1874, 1,639 m. were in operation, of which 878 m. belonged to the state and 761 m. to private companies; 1,744 m. were in construction, 437 m. by the state and 1,307 m. by private companies. At the beginning of 1875, 451 m. had been finished, making the total length of all the railways at that time 2,090 m. Of the telegraph lines, all of which, excepting those belonging to private railway companies, are the property of the state, 4,654 m. were in operation in 1872, with 10,081 m. of wires; of these, 177 m. were submarine cables. The number of post offices in the kingdom in 1872 was 546, and the number of letters passing through the mails was 14,465,572.—Previous to 1858 the unit of money in Sweden was the *riksdaler* (government dollar). The wars prior to 1815 depreciated the Swedish paper money greatly, and the government notes were of less value than those issued by the bank, which was an independent institution, though under the management of directors appointed by the legislature. The specie dollar was 106 cts., the *riksgalds* (royal debts) dollar 26¼ cts., or four to the specie dollar; while the *riksdaler banco*, or bank dollar, was

39⅜ cts., or three eighths of the specie dollar and 1½ of the riksgalds. The riksdaler banco hence became the official money of accounts. All three (the specie, banco, and riksgald) were divided into 48 *skillings*, and the skilling into 12 *rundstyks*. In 1854 the diet adopted a decimal system, which was put into operation Jan. 1, 1858. In this system the riksgald dollar (26½ cts.) is the unit; it is called the *riksdaler ryksmint*, and divided into 100 *öres*. In 1872 a convention was signed at Stockholm by the plenipotentiaries of Sweden, Norway, and Denmark, for the introduction of a common system of coinage into the Scandinavian kingdoms. This was ratified by Sweden, and the new coinage was put into circulation on Jan. 1, 1875. The basis is gold, with silver and bronze for the smaller coins, the unit being the *kronor* or crown (26⅘ cts.) of 100 öres. The gold coins, which are an alloy of 90 parts gold and 10 copper, are the 10-crown piece and the 20-crown piece. The silver coins have an alloy of copper, and consist of pieces of one and of two crowns, and of 50, 40, 25, and 10 öres respectively. The bronze coins are of 95 parts copper, 4 tin, and 1 zinc, and are of the respective values of 1, 2, and 5 öres. In weights, the Swedish pound, which is the unit, is equal to 0·937 of the pound avoirdupois; it is subdivided into 100 *orts* of 100 *korns* each; 100 pounds make a *centner*, and 100 centners a *nyläst*. In length, one Swedish foot is equal to 0·974 of an English foot, and is divided into 10 inches of 10 lines each. The Swedish mile is equal to 6·6235 English miles; the square mile to 43·87 English square miles. The measure of contents has the Swedish cubic foot for its unit, divided into 10 *cans* of 100 cubic inches each.—Sweden and Norway form a single kingdom, but have separate internal administrations, the king residing alternately in each country. (See NORWAY.) The government is a limited monarchy, hereditary only in the male line. The king is sole executive of the realm, commander of the land and sea forces, and head of the church, and has the right to preside in the supreme court of justice. He must be a member of the Lutheran church. His person is inviolable, and his action exempt from censure, but he is required in Sweden to advise and consult with a council of state composed of ten members, two of whom, called ministers of state, hold the portfolios of justice and of foreign affairs, and eight of whom are called councillors of state; of the latter, five are the chiefs respectively of the departments of marine, war, finance, ecclesiastical affairs, and the interior, and three have only consultative voices. All the members of the council are responsible for the acts of the government. In practice the king submits all measures excepting military and diplomatic affairs to his councillors, but he is not bound to follow their advice. If he proceeds to unconstitutional measures, they must make a formal protest or be held responsible before a high court convened for their trial. During the absence of the king in Norway, Sweden is governed by a regency named by him, consisting of a prince of the blood or a minister of state and three councillors. In case of his absence in a foreign country, or of the minority of the sovereign, the two kingdoms are governed by a joint regency consisting of ten Swedes and ten Norwegians. The law-making power is vested in a legislature called the diet, which previous to the amendment of the constitution in 1866 consisted of four houses, respectively of the nobles, clergy, burghers, and peasants, but is now divided into an upper and a lower chamber. The upper chamber has one member for every 30,000 of population (in 1874, 128), who are elected for nine years and receive no salary. Each member must be more than 35 years old, and must have possessed for at least three years previous to election real estate of the taxed value of 80,000 riksdalers, or an annual income of 4,000 riksdalers. There are only 6,000 Swedes eligible to a seat in this chamber, of whom about 1,750 reside in the country. Members are elected indirectly, in cities by the municipalities and in the country by the 25 provincial assemblies. These assemblies, called *landsting*, are selected by electors chosen by the people in the communal or parish elections, in which each property owner, male or female, is allowed one vote to each 100 riksdalers of taxable income. In the cities no one can cast more than 100 votes, the number authorized by 10,000 riksdalers of income. The lower chamber consists of one representative for every 10,000 inhabitants of towns, of one deputy for every rural district whose population is less than 40,000, and two deputies for those of more than 40,000. In 1874 the number of members was 194, of whom 56 represented the towns and 138 the rural districts. They are elected for three years, and receive each a salary of 1,200 riksdalers for the session of four months and travelling expenses. They are chosen generally by direct vote, although they may be by indirect vote at the option of a district. Every male Swede 21 years of age and over, who owns real property of the assessed value of 1,000 riksdalers, or holds a five years' lease of property of the value of 6,000 riksdalers, or pays an income tax on 800 riksdalers is entitled to vote in their election; and if he is 25 years old and has possessed these property qualifications for one year preceding the election, he may be elected a member. The diet assembles every year, on Jan. 15, without special convocation. The king appoints the president and vice president of each chamber. The diet appoints: 1, a lawyer as procurator general to superintend the execution of the laws by judges and officers; 2, a committee of 48 members, every third year, to report whether the members of the supreme court deserve to retain their positions; and 3, a committee of six members, also

every third year, to watch with the procurator general over the liberty of the press. Laws for changing or abolishing rights of the nobility require the consent of an assembly of nobles, and ecclesiastical laws can be enacted, changed, or abrogated only with the consent of a general church assembly. The king has the right of absolute veto of any measure passed by the diet. The judiciary consists of the supreme court of the kingdom, composed of 16 judges in two divisions, which interprets the laws and renders justice in the name of the king, who when he presides has the right of two votes; three royal courts of justice, sitting at Stockholm, Jönköping, and Christianstad; a royal court of military justice; and a supreme court of admiralty. There are also throughout the kingdom petty courts, of which the clergy are often magistrates.—The estimate of receipts and expenditures of the administration for the year 1875 is as follows:

GROSS RECEIPTS.

| | | |
|---|---|---|
| Ordinary revenue, including land tax, receipts from railways, telegraphs, forests, tonnage dues, &c. | | 25,135,000 |
| Extraordinary: | | |
| Customs | 19,500,000 | |
| Posts | 3,400,000 | |
| Stamps | 1,880,000 | |
| Impost on spirits | 12,000,000 | |
| " on beet sugar | 60,000 | |
| Income tax | 2,800,000 | 39,640,000 |
| On account of the public debt: | | |
| Cash, interest, &c. | 11,037,939 | |
| Loan of 1872 for construction of railways | 9,437,000 | |
| Remainder of do. and new loan | 14,000,000 | 34,474,939 |
| Total receipts | | 99,249,939 |

EXPENSES.

| | | |
|---|---|---|
| Ordinary: | | |
| Royal household | 1,266,000 | |
| Justice | 3,340,400 | |
| Foreign affairs | 609,365 | |
| Army | 11,710,400 | |
| Navy | 4,459,100 | |
| Interior | 11,591,500 | |
| Church and public instruction | 6,822,900 | |
| Finance | 10,498,000 | |
| Pensions | 1,539,135 | 51,836,800 |
| Extraordinary, including railway construction, army and fleet, and supplement to budget of 1874 | | 28,447,108 |
| On account of the public debt: | | |
| Liquidation of loans for railway construction | 11,557,185 | |
| Loaned for construction of private railways | 2,000,000 | |
| Various expenses | 5,408,845 | 18,966,031 |
| Total expenses | | 99,249,939 |

At the close of 1873 the total public debt amounted to about 122,080,000 crowns. From this must be subtracted credits of about 32,-240,000, which leaves the actual debt about 89,840,000 crowns. The whole of this debt was contracted for railway construction, and all in Germany, with the exception of two loans of about 30,000,000 crowns in the aggregate, which were negotiated in London. All the loans are paid off gradually by means of a sinking fund. In 1872 the diet authorized the emission of a new loan of 24,000,000 riksdalers, at 4 per cent., to continue the construction of the railways; but the budgets of 1872 and 1873 having exhibited surpluses, only 6,650,000 had been issued up to May, 1874. Sweden has but one colony, the island of St. Bartholomew in the West Indies, the administration of which costs 25,000 crowns per annum.—The army of Sweden is composed of five classes of troops, the *värfvade* or enrolled troops, the *indelta* or military colonists, the *beväring* or conscripted troops, the militia of Gottland, and volunteers. The active army consists of the first two of these classes. The värfvade are enlisted usually for six years; they comprise a body of about 6,000 men, among which are the royal life guards, the artillery, the engineers, and one regiment of hussars. The indelta consist of about 25,000 men, 21,000 of whom are infantry, the remainder cavalry. This body, which was established by Charles XI., is peculiar to Sweden. The men are cantoned in military districts, where they are provided for by the holders of crown lands in those districts. Each man has also assigned to him a house and a piece of land, which he cultivates for himself. The infantry are exercised annually 30 days and the cavalry 46 days. The remaining three classes constitute the reserve. The beväring are drawn by annual levy from the whole male population between the ages of 20 and 25. The right to purchase substitutes was abolished by the diet in 1872. In 1873 this body numbered 86,101 men. The militia of Gottland have a separate command, and cannot be obliged to serve out of the island; they number usually about 8,000 men. The volunteers were first organized in 1861. In time of peace they are subject only to their own rules, although their commanders are chosen by the king; but in war they may be compelled to serve under the military authorities. About 20,000 were enrolled in 1873. The effective force of the kingdom in 1873, including all the five classes, was 150,773 men. The navy was entirely reorganized in 1873, and now forms a single body called the royal fleet, with two stations, at Stockholm and Carlscrona. It consisted in 1874 of the following vessels: steamers—1 ship of the line with 66 guns, 1 frigate with 22 guns, 2 corvettes with 14 guns, 4 monitors with 8 guns, 10 small monitors (4 constructing) with 10 guns, 12 gun boats with 21 guns, 4 vessels without guns, 1 transport with 1 gun, and 2 despatch boats with 5 guns; sailing vessels—1 frigate with 36 guns, 5 corvettes with 102 guns, 1 brig with 10 guns, and 1 schooner with 8 guns; rowing vessels—4 mortar boats with 5 guns, 44 gun boats with 98 guns, and 40 launches with 49 guns; in all, 133 vessels with 455 guns. The navy is officered by 2 rear admirals, 6 commanders, 20 captain-commanders, 43 captains, 43 lieutenants, and 26 sous-lieutenants; it has an effective force of about 7,000 men, and a reserve of 35,000 men.—The Lutheran is the established church of Sweden, but all sects are tolerated. Previous to 1873,

when the church assembly assented to the act of the diet permitting civil marriages and marriages by dissenting ministers, no one not confirmed in the Lutheran faith could be legally married. Every Swede who does not claim to belong to some one of the dissenting sects must be confirmed at the age of 14 or 15 and partake of the sacrament, upon which he receives a certificate from his pastor. If he neglects the requirement, he is subject to many inconveniences, and is not entitled to the same burial rites as a confirmed person. The clergy, who must be graduates of one of the universities, are generally moral and high-toned, and exercise a controlling influence in society. In the country parishes they are often magistrates as well as pastors. They receive in general a liberal income from permanent funds, tithes, and fees, but some are poorly paid. They are usually elected in parish meeting and commissioned by the king. The head of the church is the archbishop of Upsal, who has under him 11 bishops, respectively of Linköping, Skara, Strengnäs, Westeras, Wexiö, Lund, Gothenburg, Calmar, Carlstad, Hernösand, and Wisby. The archbishop and bishops are nominated by the king from a list of candidates presented by the dioceses. Ecclesiastical matters are discussed in convocation, but are subject to the decision of the king.—Public instruction is gratuitous and compulsory, and it is rare to meet with any one who cannot read and write. Primary schools exist in every parish, excepting in the northern districts, which are so thinly peopled as to render movable schools necessary. Children who do not attend schools under government supervision must furnish evidence of private education. In 1870 nearly 97 per cent. of the children from 8 to 15 years of age attended the public schools. The whole number of common schools in the kingdom was 7,303, with 555,595 pupils; of these 1,164 were movable schools. In 1871 the number of male teachers in the common schools was 5,029, of whom 52 were clergymen and 1,057 church clerks; the number of female teachers was 2,776. The amount paid for the support of common schools in 1871 was 3,537,968 riksdalers, of which 2,573,927 was contributed by parishes, 842,907 by the state, and 121,133 was derived from interest on endowments. In 1870 there were 98 high schools for boys, with 756 teachers and 12,755 pupils. No high schools were provided for girls till 1873, when one was established at Carlstad. There are also technical schools and day and evening schools in the several cities. The universities of Upsal and Lund have faculties of theology, law, medicine, and philosophy. In 1873 the former had 1,611 and the latter 563 students. Preparations are nearly completed for founding a free university at Stockholm. There is a military school at Carlberg, a higher military academy for officers of engineers and of artillery at Marieberg, and a school for naval cadets at Stockholm. Libraries and collections of art, natural history, &c., exist in all the cities, and are free to the public on certain days, and there are many literary and scientific societies in the kingdom. Almost every parish, every prison, and all the large industrial establishments have their libraries. In 1875 there were 271 newspapers and periodicals published in Sweden, of which 12 were daily and 16 were illustrated.—The early history of Sweden is confused and mythical. When Odin and his Swedes entered the country, they found a great part of it in the possession of the Goths, who had dispossessed the Lapps and Finns, and the kingdom which he founded comprised only a portion of Svealand, or the central province. (See Denmark, Northmen, Norway, and Odin.) The dynasty of the Ynglings, founded by Frey-Yngve, son of the pontiff Njord, Odin's successor, ended, it is supposed, before the 8th century, with Ingjald Illrada. He was succeeded by Ivar Vidfamne, who ruled over both the Swedes and the Goths. In 829 Ansgar or Anscarius, a monk of Corbie, visited Sweden and converted many pagans, but did not succeed in establishing Christianity. About the year 1000 Olaf Skotkonung (the lap-king, so called because he received homage when an infant) was baptized, and a bishopric was erected at Skara, but Svealand would not receive Christian teachers for more than a century afterward. Constant disputes and often open war existed for centuries between the Goths and the Swedes, and their political union was not completed until the reign of Waldemar, son of Birger Jarl (Earl Birger), who was made king in 1250. Finland had in the mean while been conquered and Christianized. In 1279 Magnus Ladulas (Barnlock, so called because he protected the people's granaries from the rapacity of the nobles) ascended the throne and reigned with ability till his death in 1290. Then followed a long period of dissension between his three sons. In 1319 Magnus Smek, an infant, became king, and in the next year succeeded by right of his mother to the throne of Norway. He established his son Haco in Norway, and induced him to marry Margaret, daughter of Waldemar, king of Denmark. The three Scandinavian states being thus allied, he attempted by the aid of the kings of Norway and Denmark to abolish the senate, but was deposed and Albert of Mecklenburg was elected king in 1363. A war ensued between him and the kings of Denmark and Norway, which ended in Albert's defeat, and on July 20, 1397, by the "union of Calmar," Margaret, "the Semiramis of the North," became queen of the confederate monarchy of Sweden, Norway, and Denmark. She retained possession of the triple government till her death in 1412, and was succeeded by her grand-nephew Eric of Pomerania (XIII.). The union of Calmar was maintained with great difficulty for more than 100 years, though in 1434–'6

it was seriously perilled by the efforts of the Swedes under the leadership of Engelbert, a patriotic Dalecarlian miner, and but for his assassination by the treachery of a Swedish noble in 1436 would have been overthrown. In 1439 Eric was deposed, and his nephew Christopher of Bavaria chosen king; and on his death in 1448 Karl Knudsson, who had been regent at the deposition of Eric, succeeded him. Anarchy ensued under him and his successors till 1520, when Christian II. of Denmark became king. He exasperated the people by his cruelty, and they found a leader in Gustavus Ericsson, a noble of high rank, better known as Gustavus Vasa. (See Gustavus I.) Christian had executed as traitors and heretics many of the principal nobles, among them the father of Gustavus, and a great number of peasants. The resistance of the Swedes under Gustavus to the government of the Danish king was successful, and in 1523 they elected their leader king. In 1529 he introduced the reformation. At his death in 1560 he was succeeded by his son Eric XIV., who was deposed on account of alleged insanity in 1568 by his brother John III. (See Eric XIV.) John reigned till his death in 1592, when his son Sigismund, who had been elected king of Poland and had become a Roman Catholic, succeeded him, the late king's brother, Duke Charles, being regent till he could leave his kingdom of Poland. Sigismund determined to establish Romanism in the kingdom, against the will of the people, and showed himself so reckless and unscrupulous, that in 1599 he was deposed, and in 1604 his uncle Charles IX., who had acted as regent, was raised to the throne. (See Charles IX.) His reign was one of tranquillity in the kingdom, and in 1611 he died, leaving the throne to his son Gustavus Adolphus. (See Gustavus II.) After a reign of 21 years, the greater part of which was spent in wars with Poland and Russia for the possession of Ingria, Livonia, and other territories on the Baltic, and in the defence of Protestantism in Germany, while his affairs at home were managed successfully by the wise Oxenstiern, Gustavus closed his glorious career at the battle of Lützen in 1632, and his daughter Christina, then six years of age, succeeded him. (See Christina.) Oxenstiern was invested with the chief management of affairs; Baner, Torstenson, and other Swedish generals won new victories; and the kingdom for a time prospered, and by the peace of Westphalia in 1648 received western Pomerania and other accessions of territory. After Christina's coming of age, her want of fixed principles and the violence of her disposition soon plunged the country into debt and trouble, and in 1654 she abdicated in favor of her cousin Charles X. His reign of six years was marked by brilliant campaigns against the Danes and in Poland, and acts of great personal bravery; but his victories brought no advantage to Sweden, and only wasted her resources. (See Charles X.) He died in 1660, and was succeeded by his young son Charles XI., during whose minority a peace was concluded by which the kingdom had 10 or 12 years of tranquillity. In 1676 began a war with the elector of Brandenburg and the Danes, which was continued with varying success, though for the most part with disaster, till 1679, when the peace of St. Germain, leaving the Danes at the mercy of the Swedes, enabled the latter to regain more than they had lost. An advantageous peace was concluded between the two kingdoms, and confirmed by the marriage of Charles to Ulrica, the daughter of the Danish king. During the remainder of his life he devoted his attention assiduously to the settlement of the troubles existing between the nobles and the peasants, and in 1693 prevailed upon both parties to give him the power to alter the constitution as he pleased. He died in 1697, bequeathing to his son Charles XII. this absolute power. (See Charles XII.) The warlike career of this remarkable but reckless king, who humbled Frederick IV. of Denmark and Peter the Great of Russia, and dethroned Augustus II. in Poland, but succumbed at Poltava, well nigh reduced his country to ruin. At his death in 1718, his sister Ulrica Eleonora, wife of Frederick of Hesse-Cassel, after renouncing absolute authority and accepting a constitution from the nobles which restored their power, was elected by the diet to the succession. She soon surrendered the government to her husband, whose reign was a period of humiliation, during which Sweden made peace with her enemies on most disadvantageous terms, and gave up most of her Transbaltic possessions, including Livonia, Esthonia, and Ingria, which had been occupied by Peter the Great. War with Russia in 1741 resulted in defeat, and the cession in 1743 of eastern Finland. Frederick died childless in 1751, and was succeeded by Adolphus Frederick of Holstein-Eutin, bishop of Lübeck, whose election as successor had been made by the empress Elizabeth of Russia a condition of the peace of 1743. French influence corrupted the senate during his administration, and involved the country in a disastrous war with Prussia. After a turbulent reign of 20 years he died in 1771, and was succeeded by his son Gustavus. (See Gustavus III.) The revolution of August, 1772, by which Gustavus attained absolute power, and the wars which followed with Russia and Denmark in 1787, and the act of safety of 1789, which abolished the senate, were the most marked events in the Swedish history of that time. He was assassinated in 1792, and his son Gustavus IV. (see Gustavus IV.) ascended the throne; but as he was a minor, his uncle the duke of Södermanland (Sudermania) was appointed regent. In 1809 the king's imprudence and tendency to insanity led to his compulsory abdication, and his uncle was declared king under the title of Charles XIII. (See Charles XIII.) The peace made

with Russia at this time deprived Sweden of Finland. A new constitution was decreed, and the prince of Holstein-Augustenburg was elected heir to the throne as crown prince. The sudden death of this prince in April, 1810, led very unexpectedly to the nomination of Bernadotte, prince of Ponte Corvo (see BERNADOTTE), as crown prince, whose success in securing Norway to Sweden (the rest of Swedish Pomerania being given up) endeared him to the people. In 1818, on the death of Charles XIII., he ascended the throne as Charles XIV. John. During his reign Sweden prospered, commerce, the arts, and manufactures made rapid progress, and the moral and social condition of the people was greatly advanced. His son Oscar I. succeeded him at his death in 1844, and encouraged the moral, social, and political progress of the country. (See OSCAR I.) At his death in 1859, he was succeeded by his son Charles XV., who had been regent of the kingdom since 1857 in consequence of King Oscar's illness. (See CHARLES XV.) During the Crimean war Sweden and Norway remained neutral. Many constitutional reforms were effected during Charles's reign. On his death in 1872 without male offspring, he was succeeded by his brother Oscar II., who has continued his liberal policy. (See OSCAR II.)

**SWEDEN, Language and Literature of.** The Swedish is one of the Scandinavian tongues, and as such belongs to the Germanic (or Teutonic) branch of the family of the Indo-European languages. (See GERMANIC RACES AND LANGUAGES.) Though Old Norse proper was the speech of the whole Scandinavian peninsula and of Denmark until the 11th century, its dialects varied considerably even in the most primitive times, and out of one or more of those ancient dialects the modern Swedish was developed. The change was so slow that the Icelandic lays and sagas were still understood at the Swedish courts as late as the 14th century. (See ICELAND, LANGUAGE AND LITERATURE OF.) In its earlier stages the Swedish was influenced by the German through the commercial connection of Sweden with the Hanseatic towns, by the Latin through the Catholic priesthood and the monastic institutions, and by the Danish through the political union of Sweden and Denmark subsequent to the pact of Calmar (1397). The reformation again subjected it to German influences, but it was less affected by them than was the Danish. The language was greatly purified and a multitude of foreign vocables driven out by the efforts of the zealous Icelandic scholars of the latter half of the 17th and first quarter of the 18th century. But later in the last century the French tastes prevalent at the court and in the literature introduced a large number of Gallic words, many of which, however, have been since superseded by genuine Scandinavian derivatives. Several dialects are now spoken. In the northern provinces the approximation to the Old Norse or Icelandic forms is much more marked than in the southern, where Danish and German influences have been felt; the southern dialects of Scania and Blekinge have great similarity to the Danish, and that of Dalecarlia presents the greatest departure from the written language, while that of Södermanland approaches it the nearest. Swedish is also the language of the educated classes, and partly of the press, in the Russian grand duchy of Finland.—The Swedish alphabet has 28 letters, the same as in English, with the omission of *w* (in Swedish formerly the equivalent of *v*, by which it is now generally replaced) and the addition of *ä*, *å*, *ö*. Formerly the German character was mostly used in Swedish works, but now the Latin character prevails, though the former is still sometimes to be found. A letter peculiar to the Swedish is *å*, which is pronounced almost like the English *o* in *note*. The vowels *a*, *e*, *i*, *ä*, and *ö* are pronounced as in German; *o* has two sounds, either similar to that of the English *o* in *move*, but intermediate between *o* and *u*, or equivalent to the English *a* in *fall*. The sound of *u* is intermediate between the German *u* and *ü*. *Y* is pronounced almost like the German *ü*. *G* before *e*, *i*, *y*, *ä*, *ö*, has a sound like the English *y* in *you*. *J* has the same sound. *D*, *g*, *h*, and *l* before *j*, and *h* and *f* before *v*, are mute. *K* before *e*, *i*, *y*, *ä*, *ö*, is soft and pronounced like *ch* in *much*. *Sk* before the same letters, and the combinations *skj*, *sj*, *stj*, are pronounced like the English *sh*. The indefinite article *en* (masc. and fem.) and *ett* (neut.) is placed before the noun; as *en häst*, a horse, *ett bord*, a table. The definite article is *den* in the masculine and feminine, *det* in the neuter, and *de* in the plural for all genders; but it is also expressed by only adding in the singular number *en* or *n* to masculine and feminine substantives, and *et* or *t* to the neuter, and in the plural *ne*, *na*, *a*, *en*; or, thirdly, both these ways may be combined, as *den mannen*, the man, *det bordet*, the table, *de hästarne*, the horses. Substantives have a distinct case ending only in the genitive, which is formed by the addition of *s*. The plural of substantives is formed by adding *or*, *ar*, *er*, or *en*; and in some words the singular and plural are alike. The adjectives are formed after two declensions, the first of which has a separate form for the neuter gender, while the second has only one form for all the three genders. The second person singular pronoun is used in conversation only among intimates or when addressing inferiors; otherwise the title of the person addressed, or *Herr* (sir, Mr.), *Fru* (madam), or *Mamsell* or *Fröken* (miss), with the verb in the third person, must be used; thus: Have you seen the book? *Har Herrn* (Has the Mr.) *sett boken?* Verbs have a strong and a weak form of conjugation, and two simple tenses, present and imperfect. The passive is formed by adding *s* to the active; as, *att skära*, to cut, *at skäras*, to be cut; *jag kallar*, I call, *jag kallas*, I am

called. Throughout the verbs the singular is the same in all three persons; in the plural the first and third are alike, and the second ends in *en*. Among the best grammars of the language are those of Rydqvist, *Svenska Språkets Lagar* (4 vols., Stockholm, 1850–'73); Strömborg, *Svensk Språklara* (Stockholm, 1858); Funk, *Praktischer Lehrgang zur schnellen und leichten Erlernung der schwedischen Sprache* (Leipsic, 1872); and May, "A Practical Grammar of the Swedish Language" (4th ed., Stockholm, 1873). Among the best lexicons are Dalin's (2 vols., Stockholm, 1850–'54), and especially Kindblad's (3 vols., Stockholm, 1840–'73).—Literature. The literary history of Sweden has been very conveniently divided into six periods. I. 1250 to 1520. The earliest writings extant in the Swedish language are the ancient provincial laws, of which the oldest compilation, that of the province of Westergötland, was probably made about the middle of the 13th century. The poetical spirit of the nation was first developed in the *Kämpavisor*, or heroic ballads, and a little later in the *Riddarvisor*, or chivalric ballads. Of these several collections have been edited; a few of them may perhaps be ascribed to the latter part of the 13th century, but the greater part of them belong to the 14th and 15th centuries. Of greater influence upon the written language were the romances of chivalry, mostly translations and imitations of those then popular in central Europe. As many of them were translated between 1300 and 1312 by order of Euphemia, queen of Norway, they are collectively called *Drottning Euphemias Visor*, "Queen Euphemia's Songs," though many are in prose. The only noteworthy productions of the 14th century are *De stora och de gamla Krönikarna*, "The Great and the Old Chronicles," narrating the leading events of Swedish history; a translation of the life of St. Anscarius, and a "Legend of the Nun Elisif," by Bishop Hermanni; some lyrics composed by Bishop Thomas; the "Revelations" of St. Brigitta, abbess of Wadstena, and her daughter's *Sjellina Tröst*, "Soul's Trust," a paraphrase of a Latin treatise. The literary monuments of the 15th century are principally the *Codex Vadstenensis*, a collection of legends, essays, letters, and diaries, made by the nuns and monks of Wadstena; an anonymous judicial treatise, *Domarereglorna*, "Rules for Judges;" and a curious political work, *Om Konunga- och Höfdinga-styrelsen*, "On the Government of Kings and Rulers," based upon the book of an obscure Latin author, Ægidius Romanus. Printing was introduced into Stockholm in 1483, the first book printed being a collection of fables styled *Dialogus Creaturarum Moralisatus*. II. 1520 to 1600. The religious contests of the 16th century gave a theological or rather polemical character to almost the entire literature. Two brothers, Olaus Petri (1497–1552) and Laurentius Petri (1499–1573), are almost the only literary representatives of this period; they made translations of the Bible, wrote chronicles, and composed verses. A liturgy known as *Rödboken*, the "Red Book," and other minor Roman Catholic productions, called forth a mass of unimportant polemical writings. All the prose and poetry of this period deserving of mention are some chronicles of the reign of Gustavus Vasa by R. Ludviksson (died 1594), P. Svart (died 1562), and S. Elofsson; a few hymns translated from the German, and some popular ballads; a dull religious drama, *Judas Redivivus*, by Rondelitius; some hymns and a love song by King Eric XIV.; and a *Visa*, or lay, by J. af Hoja (died 1535). III. 1600 to 1718. The learned foreigners who flocked to the court of Christina, among them Descartes, Bochart, the younger Heinsius, Gronovius, Pufendorf, and Scheffer, gave an impetus to higher culture in Sweden; but as they wrote in Latin, they did little for the development of the vernacular literature. The investigations of the Icelandic literary monuments by Olof Verelius (1618–'82), Olof Rudbeck (1630–1702), and Johan Peringskjöld (1654–1720), causing the publication of Icelandic texts, principally the Eddas, were of more importance in this respect. The historical writings of Eric Tegel (died 1638), A. Girs (died 1639), Widekindi (1620–'97), Werwing (died 1697), and Adlerfeldt (1671–1709) exhibit a considerable improvement in the use of language, though they can hardly claim to be much more than heavy compilations of facts and materials. The continued religious controversies, at this time between Lutheranism and Calvinism, called into the field but few theologians who wrote in any language but Latin. The exegetical works and ecclesiastical histories, among which those of Paulinus (died 1646), Rudbeckius (1581–1646), and Winstrup (died 1679) stand prominent for theological learning, were also written in Latin, as well as the works that appeared on other subjects of scientific research. In jurisprudence the names of M. Vexionius and J. Stjernhök (1596–1675) are well known; in geography and travels, Count E. Dahlberg (1625–1703) published a *Svecia Antiqua et Hodierna*, with 353 maps and engravings of Swedish towns and castles; in classical philology, Gezelius, Lagerlöf, and Freinshemius distinguished themselves; and in botany, Rudbeckius paved the way for Linnæus. But the progress made in the literary use of the vernacular is almost wholly due to the few who attempted romance and poetry. In poetry Georg Stjernhjelm (1598–1672) held the foremost place. His most complete poetical work is *Hercules*, a sort of didactic epic in hexameters, exhibiting large imaginative power and much poetic skill. Of his masques the best is *Den fangne Cupido*, "The Captive Cupid." Stjernhjelm was the first writer of sonnets in Swedish. The drama consisted generally of dull imitations of Olaus Petri and Rondelitius, the chief writers being the historian

Messenius, who attempted to exhibit the whole of Swedish history in a series of dramas, S. P. Brask (1613–'68), and A. J. Prytz (1590–1655). More classically dramatic in form, but scarcely better in style, are the *Rebecca* of J. Beronius and the *Rosimunda* of U. Hjärne, while but little more praise can be bestowed upon the dramatic allegories of J. P. Chronander. The lyric writers may be divided into the Italian and the German school. To the former belonged G. Dahlstjerna (1658–1709), author of the *Kungaskald*, a half heroic, half elegiac poem in *ottave rime* on Charles XI., and of an unsuccessful translation of Guarini's *Pastor fido;* and G. Rosenhane (1619–'84), whose longest metrical attempt, *Venerid*, is a collection of 100 sonnets. The chief representatives of the German school were S. Columbus (1642–'79), whose lyrics and pastorals are now nearly forgotten; L. Johansson (died 1674), whose *Helicons Blomster*, "Flowers from Helicon," published under the pseudonyme of Lucidor, is a collection of epithalamiums, elegies, and erotic songs, which are less remarkable than his hymns, and P. Lagerlöf (1648–'99), author of a love song of great popularity in its day. The many-sided Spegel, some of whose hymns are worthy of mention, wrote two heavy and monotonous poems, borrowing his titles from the two epics of Milton. C. Arosell is known as the author of a volume of *Ofverskrifter*, or epigrams, a few of which are of merit. IV. 1718 to 1772. These years embrace a time of great literary activity. The natural sciences, under the influence of the world-famous Linné or Linnæus, occupy the first place. (See Linnæus.) That great naturalist was surrounded by a crowd of pupils, a large number of whom became celebrated; among them P. Forskal (1736–'63), who undertook a scientific journey to Egypt and Arabia, and whose researches were published by Niebuhr; and C. Bjerkander and J. G. Wahlbom, who illustrated the flora of northern Europe. P. Artedi (1705–'35) wrote a treatise on ichthyology, which Linnæus edited in 1738. To physiology belong the *Œconomia Regni Animalis* and *Regnum Animale* of Swedenborg (1688–1772). The entomological works of C. F. de Geer (1720–'78), in French, are still esteemed. Eminent in chemistry were Torbern Olof Bergman (1735–'84), who laid the foundation for the science of crystallography; A. F. Cronstedt (1722–'65), the discoverer of nickel; and J. G. Wallerius (1709–'85). Much attention was paid to mining by M. von Bromel (1679–1731), Swedenborg, and others. Olof Rudbeck the younger (died 1740) distinguished himself in several sciences; he published among others a work on ornithology in three volumes. N. Rosén von Rosenstein (died 1773) was the reformer of medical science in Sweden. Astronomy was illustrated by such names as A. Celsius (1701–'44), S. Klingenstjerna (1689–1785), and P. W. Wargentin (1717–'83); mechanics by C. Polhem (1661–1751) and Swedenborg; and mathematics by J. Faggot, C. Falkengren, E. O. Runeberg, and others. Jurisprudence was represented by D. Nehrman (died 1769) and O. Rabenius (1730–'72). S. Alnander, J. Benzelius, P. Munch, L. P. Halenius, P. Muhrbech, and J. Serenius were the chief writers in the various departments of theology; but the science produced no very eminent man except Swedenborg. (See Swedenborg.) The best known metaphysician was the Cartesian A. Rydelius (1671–1738); the system of Wolf was supported by P. Högström, N. Wallerius, and C. Mesterton; that of Locke by A. Schönberg (1737–1811), F. Kryger (1707–'77), and Runeberg. Johan Ihre (1707–'80) won fame by his *Glossarium Sveo-Gothicum*, a Swedish dialect lexicon, and by his researches concerning Ulfilas and the Mœso-Gothic language. The Icelandic scholars of the preceding generation were followed in the earlier portion of this period by J. F. Peringskjöld (1688–1725), E. J. Björner, Count G. Bonde (1682–1764), J. Göransson, and N. R. Brocman; but before the middle of the 18th century the taste for Icelandic studies had greatly declined. In geography and travels, E. Tuneld's description of Sweden and J. J. Björnstahl's travels through Europe deserve mention. In history, as in polite literature, Olof Dalin (1708–'63) stands at the head of this period. His journal *Den Svenska Argus*, "The Swedish Argus" (1732–'4), an imitation of the English "Spectator," exerted a weighty influence upon the prose style of the language and the literary taste of the nation; and his *Svea Rikes Historia*, "History of the Swedish Realm," though wanting in critical ability, is eloquent and pleasing. A more rigorous examination of evidence characterizes the Swedish histories of A. af Botin (1724–'90) and P. Schönström. The history of Charles XII. by G. Norberg (1677–1744), and the "Memoirs of Christina" by J. Arckenholtz, written in French, have been of great assistance to succeeding writers. O. Celsius the younger (1716–'94) wrote histories of the reigns of Gustavus Vasa and Eric XIV., and rendered a great service to Swedish letters by establishing the *Tidningar om de Lärdes Arbeten*, "Journal of the Works of the Learned," the first critical periodical in the language. A. A. von Stjernman, C. G. Warmholtz (1710–'84), E. Benzelius (1675–1743), B. Bergius (1723–'84), G. Wallin (1686–1760), and S. Loenbom (died 1776) were laborious critics, editors, and collectors, and brought to light or illustrated a great number of early Swedish monuments. Dalin's allegorical epic, *Den Svenska Friheten* ("Swedish Freedom"), his tragedy *Brynhilda*, and his comedy *Den Afundsjuke är qvick* ("The Jealous Man is sharp-witted"), are generally pleasing, though without much depth or vigor. H. C. Nordenflycht (1718–'63), a lady, left a high name as a writer of lyrics. Count G. P. Creutz (died 1785) was the author of a tolerably felicitous pastoral, *Atis och Camilla*, and Count G.

F. Gyllenborg (1731–1809) composed lyrics, elegies, satires, and fables, in a smooth and correct, but too often prosaic style. Poets of less note were Odel (died 1773), U. Rudenschöld (1698–1783), O. Bergklint (1733–1805), and O. Kolmodin (1690–1753). Subsequent to the time of Dalin the dramatic compositions, as those of E. Wrangel, H. Hesselius, O. Celsius the younger, and others, were lifeless imitations of Gallic prototypes. Such was the case too with the tedious romances of J. H. Mørk (1714–'63), the first Swedish novelist. Molière, Voltaire, Boileau, La Fontaine, Marmontel, and Fénelon were translated and sedulously imitated. V. 1772 to 1809. The earlier portion of this period took its impress to a great extent from the character of the sovereign, Gustavus III. His influence was not beneficial to the higher walks of literature, but he founded the "Swedish Academy of Eighteen" (1786), and otherwise sought to encourage letters. The pupils of Linnæus continued to be the chief scientific men of the time, and labored earnestly for the advancement of science; among them especially C. P. Thunberg, A. Afzelius, A. Sparrman, E. Acharius, O. Swartz, A. J. Retzius, and C. Qvensel. As chemists and mineralogists, the period furnished C. V. Scheele (1742–'86), regarded as one of the founders of organic chemistry, J. G. Gahn (died 1818), to whom several chemical discoveries are due, J. J. Ankarström, and S. Rinman. D. Manderhjelm (died 1810), F. Mallet, and H. Nicander were widely known for their astronomical labors. Juridical writers were M. Calonius (died 1817), L. Tengvall, and others. Medical writers were O. af Acrel (died 1807) and D. Schulz von Schulzenheim (1732–1823). There was little literary activity in the theology of the age, but the labors of A. Knös in dogmatics and of S. Ödman (1750–1829) in exegetics were of high reputation in their day. An æsthetico-metaphysical writer was Thomas Thorild (1759–1819); another name of note in æsthetics is C. A. Ehrensvärd (1745–1800). The philosopher B. C. H. Höijer (1767–1812) based his system upon those of Fichte and Schelling. D. Djurberg and C. B. Wadström (1746–'99) wrote on geography and travels. Sven Lagerbring's *Svea Rikes Historia*, though often inaccurate, was looked upon as a national work by his contemporaries, and its author was richly rewarded by the Swedish estates. His other writings are numerous. E. M. Fant (1754–1817) compiled a *Diplomatarium* and an extremely valuable collection of *Scriptores Rerum Svecicarum*. Jonas Hallenberg (1748–1834) wrote a universal history from the beginning of the 16th century, and many other works, historical, archæological, and philological. H. G. Porthan (1739–1804) investigated the history and antiquities of Finland. Special periods or departments of Swedish history were illustrated by C. G. Nordin (1749–1812), O. Knös (died 1804), J. A. Rehbinder, S. L. Gahm, and U. von Troil (1746–1803). G. Gezelius (1736–'89) compiled the first noteworthy biographical lexicon of distinguished Swedes. Under the direct influence of Gustavus III., the French taste now became almost entirely prevalent. Gustavus himself wrote some dramatic pieces of much merit, but all frigidly French. The favorite poets of his court were Kellgren, Leopold, and Oxenstjerna. J. H. Kellgren (1751–'95) was famous in his time in almost every branch of the poetic art; C. G. af Leopold (1756–1829), sometimes styled "the Voltaire of Sweden," wrote mainly didactic poems in the style of Pope, and serious lyrical pieces; Count J. G. Oxenstjerna (1750–1818) was the translator of Milton, and author of some descriptive poems. The lyrics of M. Choræus (1774–1806), the *Spastara* and *Medea* of B. Lidner (1759–'93), the poet of the passions, and the translations from Virgil, Horace, and Ovid by G. G. Adlerbeth (1751–1818), are still read with pleasure. A few poets escaped the general contagion. Foremost among these was Carl Michael Bellman (1740–'95), a song writer of the highest powers, who set his songs to appropriate melodies himself. Two of his friends, C. I. Hallman (1732–1800) and O. Kexél (1748–'96), were comic dramatic writers of worth. The verse of a female writer, A. M. Lenngren (1754–1817), possesses unusual grace and smoothness. A curious book of travels entitled *Min Son på Galejan*, "My Son in the Galley," by J. Wallenberg (1746–'78), is partly in verse, and abounds in a coarse but lively wit. The last years of this period, comprising the reign of Gustavus IV., exhibited little literary life. Freedom of the press was abolished in 1798, and a systematic censorship enforced. The Swedish academy was suspended for some months in 1795, Thorild was banished, Leopold was ordered away from the capital, and Höijer was not allowed to write. VI. 1809 to the present time. With the political revolution of 1809, the literature of Sweden was endowed with a new spirit, and greatly developed by a general use of the vernacular instead of Latin or French. Schools have largely improved both in number and character, and libraries have increased. The chemist Johan Jakob Berzelius (1779–1848) was a luminary of the scientific world scarcely less lustrous than Linnæus. (See Berzelius.) As botanists the reputation of three men has extended beyond their native land: Elias Fries (born 1794), K. A. Agardh (1785–1859), and G. Wahlenberg (1780–1851); while C. J. Hartman and N. Lilja are later laborers in this department. A geologist of great note was A. J. Erdman (died 1869). Zoölogy has a famous cultivator in Sven Nilsson, also the author of ethnographical and antiquarian works which have exercised a lasting influence on archæological studies. Other zoölogists of note are Thorell, Stolpe, Zetterstedt, Sundevall, and Malmgren. Entomology has been treated by J. W. Dalman (died 1828), C. J. Schönherr, J. W. Zetterstedt (died 1874),

C. G. Thomsen, whose *Skandinaviens Coleoptera* (1857–'70) is well known, and T. Thorell, author of a valuable work on European spiders. The chief laborer in ornithology, besides Nilsson, has been C. J. Sundevall (died 1875). Among mathematicians J. Svanberg, and among physicists Z. Nordmark (died 1828), F. Rudberg, F. W. von Ehrenheim (died 1828), A. J. Angström (1814–'74), and A. G. Theorell (died 1875), have gained considerable eminence. Medical science furnishes the names of A. O. Retzius (died 1860), his brother M. C. Retzius, and J. Hvasser. Prominent legal scholars have been L. G. Rabenius and his son T. Rabenius, E. Bergfalk (also known as a political economist), J. J. Nordström, F. Schrevelius, C. Nauman, J. C. Lindblad, J. G. Carlén (died 1874), and C. J. Schlytte (born 1795), the able editor of Sweden's ancient provincial codes. Sweden has a native philosophical school, whose founder, C. J. Boström (died 1866), developed the most purely idealistic system that has appeared. The Fichte-Schelling school is represented by the historian Geijer, the poet Atterbom, S. Grubbe, and N. F. Biberg (died 1827); while Hegel's theories have found defenders in E. S. Bring and J. W. Snellman. The Boströmian philosophy has recently been ably expounded by G. Nyblæus in a most important work on the history of Swedish philosophy (1873). Purely æsthetical are Atterbom, Hammarsköld, and A. Törneros. Swedish geography and statistics are much indebted to W. Tham and C. af Forsell. F. W. Palmblad, G. Thomée, Rietz, P. Læstadius, J. Berggren, G. von Heidenstam, Hedenborg, G. von Düben, A. Klinkowström, C. D. Arfwedsson, F. Bremer, C. A. Gosselman, and N. J. Andersson are prominent names in the literature of travels; and of late C. W. Paijkull (died 1872), by his account of Iceland, and A. E. Nordenskjöld, by his arctic researches, have gained an extended reputation. The study of Icelandic and its literature has been promoted by the labors of A. A. Afzelius, A. J. D. Cnattingius, Carl Säve, A. O. Lindfors, and G. Cederschjöld. A. Uppström published a critical edition of Ulfilas. In other philological departments M. Norberg (died 1826), C. M. Agrell (died 1840), O. F. Tullberg, J. Berggren, C. Landberg, and P. J. Petterson (died 1874) have distinguished themselves. The chief names in doctrinal theology are H. Reuterdahl, M. E. Ahlman, G. Knös (died 1837), L. G. Anjou, F. G. Hedberg, A. Wiberg, and N. Ignell. Peculiarly attractive from the union of candor, faith, and dialectical power are the popular religious works of P. Vikner. Among rationalists V. Rydberg is the most famous. In exegetics the prominent writers are B. J. Bergqvist, J. H. Thomander (died 1865), and Bishop Agardh; in pastoral theology the most noted are A. G. Knös and A. Z. Pettersson; in ecclesiastical history, Reuterdahl, L. G. Anjou, and J. J. Thomæus (died 1845). Among theological literature may also be included the elaborate work of Bäckman, *Försök till en Svensk Psalmhistoria* (1873). The teachings of Swedenborg have been zealously followed by J. Tybeck, C. U. Beurling, and A. Kahl. In Swedish history the first place is due to Eric Gustaf Geijer (1783–1847), whose works are models of historic composition. Anders Fryxell (born 1795) and Strinnholm also rank high as historians. Minor historical writers are P. A. Granberg, G. A. Silfverstolpe (1772–1824), J. F. af Lundblad (born 1791), A. Cronholm, A. A. Afzelius, C. G. Styffe, H. Järta, A. I. Arwidsson, F. F. Carlson (born 1811), G. Swederus, and J. Hellstenius. Political literature is chiefly devoted to questions of internal government, and one of its prominent works is a study on "The Swedish Parliament" (*Den Svenska Riksdagen*, 1873) by Rydin; recent publicists and political writers of high reputation are P. E. Svedbom (died 1857) and A. Sohlman (1824–'74), successive editors of the *Aftonbladet*, the most influential journal of the capital, J. A. Hazelius (died 1871), and M. J. Crusenstolpe (1795–1865). The works on Swedish statistics by E. Sidenbladh and C. E. Ljungberg are highly esteemed. The foremost archæologists of the period are N. Sjöborg, J. G. Liljegren (died 1837), A. E. Holmberg, B. E. Hildebrand, H. Hildebrand, Montelius, C. G. Brunius, and R. Dybeck. Works on Swedish literary history have been published by L. Hammarsköld (1785–1827), P. Wieselgren (born 1800), J. E. Rydqvist, J. Lénström, and Ljunggren. The *Biographisk Lexikon*, a biographical dictionary of celebrated Swedes, edited by Palmblad and subsequently by Wieselgren, is in 25 volumes. This is the brightest age in the annals of Swedish poetry. F. M. Franzén (1772–1847) has gained a lasting renown by his naïve and idyllic lyrics. J. O. Wallin (1779–1839) revised in 1819 the Swedish psalm book, a collection of religious verse hardly excelled in modern hymnology, and added 117 psalms by himself and 73 by Franzén, inferior to none in the book. J. D. Valerius, best known by his bacchanalian songs, and J. M. Silfverstolpe (1777–1831), rather a translator than an original poet, both belonged to the earlier part of the century. Two new poetic schools, of vast influence upon polite literature, arose at the beginning of this period, the romantic and the Gothic. The former was represented by the journals *Polyfem* (1810–'12), edited by J. C. Askelöf (1787–1848), and *Fosfores*, whence its members are sometimes styled *Fosforister* or phosphorists. At the head of this school stood P. D. A. Atterbom (1790–1855) as a poet, and Palmblad and Hammarsköld as critics. Atterbom's long poem, *Lycksalighetens Ö* ("The Island of Bliss"), his *Blommorna* ("The Flowers"), and many of his shorter lyrics, are characterized by depth of fancy and feeling. Other *Fosforister* were C. F. Dahlgren (1791–1844), author of *Mollbergs Epistlar*, an imitation of the songs of Bellman; C. E. Fahlcrantz (1790–1866), a successful hu-

morist in his *Noaks Ark*, but less happy in his religious epic, *Ansgarius;* and J. C. Nyberg (Svärdström, born 1785), a female writer of considerable ease and grace, better known as Euphrosyne. The Gothic school, which has left a more permanent impress upon poetry, developed its theories through a society, the *Göthiska Förbund* (the "Gothic Union," 1811), and a journal, *Iduna* (1811–'24). It sought its sources of inspiration in the ancient literature and mythology of the North. Foremost among its members, and foremost among all the poets of Sweden, stands Esaias Tegnér (1782–1846). (See TEGNÉR.) The historian Geijer was another member of the *Göthiska Förbund;* his lyrics are original, strong, and clear. There is more novelty and force than good poetic taste in *Asarne* ("The Gods of the North"), *Tirfing*, and the historical tragedies of P. H. Ling (1776–1839), who is better known out of Sweden as the founder of a new system of medicine or medical gymnastics. Far better in style was C. A. Nicander (1799–1839), author of *Runesvärdet* ("The Runic Sword") and other poems. Influenced by one or other of these two schools, but to a certain extent independent of both, are E. J. Stagnelius (1793–1823), whose dramas, such as *Martyrerna* ("The Martyrs"), epical poems, as *Wladimir*, and minor pieces, are marked by an admirable spirit and great beauty of diction; Erik Sjöberg (1794–1828), better known by his assumed name Vitalis, who, like Nicander and Stagnelius, died early; A. Lindeblad (born 1800), a composer of religious and secular lyrics in the spirit of Tegnér; and A. A. Grafström (1790–1865), whose poetical development was strongly influenced by Franzén. The highest rank among living poets is held by Johan Ludvig Runeberg (born 1804), a native and resident of Finland, in whose *Fänrik Ståls Sägner* ("Ensign Stal's Stories"), a series of patriotic lyrics on the Swedish-Russian war of 1808–'9, are displayed an energy of expression and a depth of poetic thought unknown to Swedish literature since the death of Tegnér. C. W. Böttiger (born 1807), the son-in-law of Tegnér, has written some musical dramas and minor pieces, distinguished by a lively fancy and a cultivated taste. O. P. Sturzen-Becker (1811–'69) wrote lyrics after the manner of Heine, and humorous sketches. Other poets are W. von Braun (1813–'60), whose humor is striking, but too often broad and coarse; Nybom (died 1865); C. W. A. Strandberg, whose pseudonymous name is Talis Qualis, and who has translated Byron and written some lyrics of great excellence; B. E. Malmström (1816–'66), Sätherberg, J. M. Lindblad; Tekla Knös, a poetess, whose claims to fame have been sanctioned by the Swedish academy; G. Silfverstolpe, Wennström, V. E. Norén, Z. Topelius, a Finlander (born 1818), E. Sehlstedt (died 1874), and many others. Charles XV. and his brother and successor Oscar II. are poets of some merit; the latter's translation of Herder's *Cid* has great excellence. Tragedies and historical dramas have been written by J. Börjesson (1790–1866), one of the *Fosforister*, whose *Eric XIV.* is one of the masterpieces of the Swedish drama; C. E. Hylten-Cavallius, Dahlgren, and Kullberg; and comedies by A. Blanche (died 1868), Jolin, Cramér, F. Hedberg (at present the leading writer for the stage), Granlund, Beskow, and others. No romances stand higher than those of three female writers, Fredrika Bremer (died 1865), whose first work (1828) was styled *Teckningar ur Hvardagslifvet* ("Sketches of Every-Day Life"); E. S. Carlén (born 1807), a prolific and popular authoress of novels of society; and Baroness Knorring (died 1833). All of these are widely known both in Europe and America through numerous translations. Of the imitators of Sir Walter Scott, the highest name is perhaps the learned and versatile V. F. Palmblad (1788–1852), celebrated as a geographer, critic, biographer, and politician of the ultra conservative school, whose *Aurora Königsmark* was one of the earliest readable fictions in Swedish. Equally versatile was C. J. L. Almquist (1793–1866), whose tales, and especially a collection called *Törnrosens Bok*, are rich in variety and fancy. Other romancers are Count P. G. Sparre (born 1790); F. Cederborg (born 1784), author of *Ottar Tralling* and *Uno von Trasenberg*, historical fictions of much interest; C. F. Ridderstad (born 1807), an imitator of the Dumas school; Kjellman-Göransson, Zeipel, Bjursten, O. P. Sturzen-Becker; C. A. Wetterberg (born 1804), a popular writer of sketches and tales under the assumed name of Onkel Adam; G. H. Mellin (born 1803); and Viktor Rydberg, statesman, metaphysician, and essayist, who has produced at least one powerful work of fiction, *Den siste Atenaven* ("The last Athenian"). Claude Gérard (a pseudonyme) and Mrs. M. S. Schwartz (born 1819) enjoy at present the greatest popularity as novelists. As translators may be mentioned C. A. Hagberg, author of an accurate and spirited version of the complete works of Shakespeare; Andersson, translator of Goethe; and N. Lovén, who has rendered the poems of Dante and Camoens into Swedish verse. Most of the higher efforts of literature in English, French, German, Italian, and Danish, especially in fiction, have been translated within the last 30 years. Sweden supports 271 newspapers, one of which, *Svenska Veckobladet*, has a circulation of 50,000 copies. On the whole the last 15 years has been a period rather of political than of literary activity, yielding comparatively few works of high æsthetical value.

**SWEDENBORG, Emanuel**, a Swedish philosopher, born in Stockholm, Jan. 29, 1688, died in London, England, March 29, 1772. He was the son of Jesper Swedberg, bishop of Skara (see SWEDBERG), the name being changed to Swedenborg in 1719 on the occasion of the ennobling of the family. This advancement enti-

tled him, as head of the family, to a seat in the house of nobles of the Swedish diet, but did not confer the title of baron, as has been supposed. Emanuel was educated at Upsal, completing his studies in 1709. After two years of travel in England, Holland, and France, he went to reside at Greifswald in Pomerania, then a Swedish town, and busied himself with scientific research. He also wrote some Latin fables, which were published under the title of *Camena Borea.* A collection of Latin poems, written by him during his travels, was also published about the same time in a volume entitled *Ludus Heliconius.* In 1716 he returned to Sweden and established a periodical called *Dædalus Hyperboreus*, devoted to mathematics and mechanics, which appeared irregularly for two years. During this time he had become intimate with Christopher Polhem, an eminent engineer, and Polhem introduced him to Charles XII., who appointed him assessor extraordinary of the college of mines, and associate engineer with Polhem. For two years Swedenborg maintained close personal relations with the king, and assisted him much in his military operations. During the siege of Frederickshald, at which Charles met his death, Swedenborg constructed, under Polhem's direction, the machines by which several vessels were transported overland from Strömstad to the Iddefiord, 14 miles. At the king's suggestion, it is said, Polhem betrothed his daughter to Swedenborg; but as the young lady preferred another man, Swedenborg relinquished his claim and never married. From 1717 to 1722 he published pamphlets on scientific subjects; among them one describing a method of determining longitude by means of the moon. In 1721 he made a short tour on the continent, visiting mines and smelting works. On his return in 1722 he was promoted to be full assessor of mines, and for the next 12 years he devoted himself to the duties of that office, refusing the professorship of mathematics at Upsal in 1724. In 1734 he published *Opera Philosophica et Mineralia* in three large folio volumes, illustrated with numerous plates, viz.: vol. i., *Principia;* vol. ii., *De Ferro;* vol. iii., *De Cupro et Orichalco.* In the same year also appeared his *Prodromus de Infinito.* In 1736 he began another tour of travel, which, with study and writing, occupied him for several years. In 1740–'41 he published his *Œconomia Regni Animalis*, in two parts, and in 1744–'5 his *Regnum Animale*, in three parts. Between 1729 and 1741 he was elected successively a member of the academy of sciences at Upsal, corresponding member of the imperial academy of sciences at St. Petersburg, and member of the academy of sciences at Stockholm. His series of scientific publications ended in 1745 with the treatise *De Cultu et Amore Dei*, &c., in which is set forth, under the form of a prose poem or allegory, his theory of the process of creation. Thereafter, as he says, he was called by God to the work of revealing to men a new system of religious truth. For that end he was permitted to converse with spirits and angels, and behold the wonders of the spiritual world. That he might be more free to perform his task, he resigned his assessorship, retaining half the salary by way of pension. He devoted himself first to the study of the Bible in the original, and then to the writing of books explanatory of his new doctrines, which were published entirely at his own expense. From 1749 to 1756 appeared the *Arcana Cœlestia* (8 vols. 4to), containing a commentary on Genesis and Exodus, interspersed with accounts of "wonderful things seen and heard in heaven and in hell." This was followed in 1758 by the *De Cœlo et Inferno*, *De Telluribus in Mundo*, *De Ultimo Judicio*, *De Nova Hierosolyma*, and *De Equo Albo.* In 1763 were published the four doctrinal treatises: *Doctrina Vitæ*, *De Fide*, *De Domino*, and *De Scriptura Sacra*, with a *Continuatio de Ultimo Judicio*, and the treatise *De Divino Amore et de Divina Sapientia.* In 1764, the *Divina Providentia* appeared; in 1766, the *Apocalypsis Revelata;* in 1768, *De Amore Conjugiali;* in 1769, *Summaria Expositio Doctrinæ* and *De Commercio Animæ et Corporis;* and in 1771, the *Vera Christiana Religio.* Besides these, he left at his death an immense mass of manuscripts, of which the following have been since printed: *Itinerarium*, *Clavis Hieroglyphica*, *Opuscula*, *Apocalypsis Explicata*, *Adversaria in Libros Veteris Testamenti*, *Diarium Spirituale*, *Index Biblicus*, *Sensus Internus Prophetarum et Psalmorum*, *Dicta Probantia*, *De Athanasio Symbolo*, *De Charitate*, *Canones*, *Coronis Veræ Christianæ Religionis*, and *Invitatio ad Novam Ecclesiam.* Copies of a few of these manuscripts have recently been reproduced by the photolithographic process, by subscription, not so much for circulation as for the sake of preserving the contents of the originals from destruction by decay.—Swedenborg's manner of life was simple and modest. He spent much of his time, in later years, in Holland and England, for which countries he expressed great admiration on account of the freedom of speech and writing permitted there. He made no efforts to gain proselytes to his doctrines further than by printing and distributing his writings, and never referred to his intercourse with the spiritual world except when questioned. Several instances are reported of his obtaining information from departed souls respecting affairs unknown even to their families, and describing events in distant places in advance of news by the ordinary means of communication. It is related that, as he lay on his deathbed in London, Ferelius, a Swedish clergyman, solemnly adjured him to tell the truth in regard to his teachings. Swedenborg raised himself half upright in bed, and placing his hand on his breast said with emphasis: "As true as you see me before you, so true is everything I have written. I could have said

more had I been permitted. When you come into eternity, you will see all things as I have stated and described them, and we shall have much to say concerning them to each other." He then received the holy supper from Ferelius, and presented him with a copy of his *Arcana Cœlestia.* A day or two afterward he peacefully breathed his last. His body was buried in a vault of the Swedish church in Prince's square, a little east of the tower. A eulogium was pronounced upon him in the Swedish house of nobles in October, 1772, by Samuel Sandels, which accords him high praise, not merely for learning and talent, but also for uprightness and fidelity in the discharge of his duties as a public functionary. Several of his acquaintances have also left written testimony to his virtuous character.—Swedenborg's scientific works have long since ceased to be of practical value, but are still highly interesting as collections of facts, and as exhibiting their author's peculiar method of philosophizing. The system he followed was substantially that of Descartes, of whom he continued to the end of his life to speak with admiration, and this led him to conclusions resembling in some striking points those of Spinoza, who was likewise a Cartesian. His "Economy of the Animal Kingdom" is the best of his many productions anterior to his theological career. In it he attempts to deduce a knowledge of the soul from an anatomical and physiological knowledge of the body, and evolves many doctrines which he afterward elaborated in his theological works. Indeed, some of his disciples hold that his seership was the natural result of his intellectual and moral development, and by no means an abnormal condition of mind. According to his own account, it came upon him gradually, and neither astonished nor alarmed him, although in its early stages he was subject to great mental excitement, the phenomena of which may have given rise to exaggerated stories of his insanity. The works written by him subsequent to this change in his mind are quite as systematic and coherent as his earlier productions, and only his claim to a divine mission, and his frequent descriptions of what he saw and heard in the spiritual world, mark them as peculiar. They are consistent from first to last, and though they appeared at intervals during a period of 27 years, they nowhere deviate from the fundamental principles laid down at the outset.—The general features of Swedenborg's theology are presented in his treatise called the "True Christian Religion." He teaches that God is one in essence and in person, and has been revealed to men as the Lord Jesus Christ. In the Lord is a trinity, not of persons but of principles, and it is these principles which are spoken of in the Scriptures as Father, Son, and Holy Ghost. The Father is the divine love, the Son the divine wisdom, and the Holy Ghost the divine operation or energy acting upon the universe. The Lord is infinite, eternal, self-existent, omnipresent, omniscient, and omnipotent, and not only the creator but the sustainer of all creation, which without him would cease to exist. For the sake of redeeming mankind he assumed a natural body born of the Virgin Mary, and glorified it or made it divine, so that it is now invisible to men, and also usually to the angels except as the sun of heaven. Redemption consisted, not in suffering vicariously the punishment of men's sins (for that could not be done, and, if it could, would be useless), but in actual combats, by means of the assumed humanity, with the powers of hell, and overcoming them. This victory restored to man spiritual freedom, which had begun to be impaired by diabolic possessions as narrated in the Gospels, and enabled him to work out his salvation. This he does by looking to the Lord, with faith in him, by repentance, and above all by a life according to the commandments of the decalogue. The chief points that Swedenborg insists on in religion are faith in the Lord and the avoidance of evils as sins against him. Upon everything else, such as outward worship, prayer and meditation, and works of eleemosynary charity, he lays but little stress. The essence of charity is love to the neighbor and occupation in some useful employment. The Word, he says, is the divine truth itself, written to reveal the Lord to man and to serve as a medium of conjunction between earth and heaven. This Word consists of the books of Genesis, Exodus, Numbers, Deuteronomy, Leviticus, Joshua, Judges, Samuel, Kings, the Psalms, the prophecies, the four Gospels, and the Apocalypse. The other books bound up with these in our Bibles are not the Word, although good and useful to the church. The distinction between the two consists in this: that the Word contains an internal or spiritual sense, which the rest of the Bible has not. This spiritual sense is symbolical, and may be discerned by the application of the law of symbolism resulting from the universal correspondence of natural with spiritual things. Thus, the garden of Eden and all things mentioned as existing in it symbolize the human soul and its affections and thoughts; and the disobedience of Adam and Eve, the alienation of mankind at a remote period from their original state of innocence. Hence, too, the decalogue forbids not merely outward sins, but the inward spiritual sins corresponding to them, and the Psalms and prophecies relate not merely to David and the Jews, but to experiences of the human soul independent of dates and localities. At the same time the literal sense alone can be relied on as a basis of doctrine, and Swedenborg is careful to cite it profusely in support of his teachings. The reason he gives for his mission is that the knowledge of true doctrine had been lost and the church destroyed by a false theology and accompanying evils of life. By the promulgation of the

truth revealed to him a new church has been established by the Lord, and thus the prophecies in the Apocalypse of the descent of the New Jerusalem have been fulfilled in their symbolical sense. The second coming of the Lord, predicted in Matt. xxiv., has also been accomplished in the same way, a last judgment having been effected in the spiritual world in the year 1757, so that we are now living under a new dispensation. The treatise on "Heaven and Hell" embodies Swedenborg's teachings on the nature of those two realms, and their relations to this world. They exist, he says, not in some other region of space, but within the natural world, as the soul of man exists within his body, being in fact in the souls of men and resting in them as our souls rest in our bodies. At death the body, which is the material envelope of the soul, is cast aside, never to be resumed, and consequently its resurrection is not to be looked for. The soul is the man himself, and is a perfect human being, with a spiritual body of its own, and rises into a conscious perception of the spiritual world, of which the man had previously been unconsciously an inhabitant. He sees and feels and possesses all the other senses, and retains all his personal characteristics. After a longer or shorter preparation in an intermediate state called the world of spirits, which lies between heaven and hell, he is drawn by his own elective affinity to the place where he belongs, and remains there to eternity. Both heaven and hell consist of innumerable societies, each composed of human beings of similar and concordant affections; and both are divided into three distinct regions, according to the degrees of perfection or depravity of their inhabitants. The *Arcana Cœlestia*, Swedenborg's largest work, is mainly an exposition of the internal or symbolical sense of Genesis and Exodus, with accounts of his experiences in the spiritual world, and various doctrinal teachings interspersed between the chapters. "The Apocalypse Revealed" and "The Apocalypse Explained" are similar expositions of the Apocalypse. In his "Conjugial Love" Swedenborg expounds his doctrine of the relations of the sexes. Males, he says, are masculine and females feminine in soul as well as in body. The masculine element is love clothed with wisdom, while the feminine is wisdom clothed with love. Hence the characteristic of man is wisdom or understanding, and that of woman love or affection. Marriage is the conjunction of two souls who complement each other, and by their union make one complete being, just as the will and the understanding make the individual. Hence the only true marriage is of one man and one woman, and it exists in the next world as well as in this. Polygamy is a degraded state, but not a sin with those whose religion permits it; but adultery is destructive of the life of the soul, and closes heaven against those who confirm themselves in it. The treatises on the "Divine Love and Wisdom" and the "Divine Providence" embody Swedenborg's spiritual philosophy, and exhibit the symmetrical relations of the various parts of his religious system. Love, he says, is the life of man. God alone is Love itself and Life itself, and angels and men are but recipients of life from him. He is very Man, and our humanity is derived from him, so that it is literally true that we are created in his image and likeness. His infinite love clothes itself with infinite wisdom and manifests itself in ceaseless operation, producing, maintaining, and reproducing the boundless universe, with all its innumerable parts and inhabitants. In like manner men, being made in the image of God, also have love or the will, and wisdom or the understanding, and the two produce in them their finite operation. It being the nature of love to desire objects upon which to exercise itself, God could not but create the universe. The creation of this and other solar systems, all of which are inhabited, was effected by a spiritual sun, which is the first emanation proceeding from God, and which is seen in the spiritual world as our sun is seen by us. By means of this spiritual sun natural suns were created, and from them atmospheres, waters, earths, plants, animals, and finally man. Angels, spirits, and devils are men who have been born and died on this or some similar planet. Hence, all things were created from God, and not out of nothing. The spiritual world is related to the natural as cause is to effect, and the supreme first cause of all is God himself. These three, end, cause, and effect, constitute three distinct or discrete degrees, which are repeated in various forms in all created things, and on a grand scale in the universe as a whole. Creation, being from God, is, like the individual man, an image of him, and hence is in the human form in its greatest and least parts, and with more or less approximation to perfection. As we are finitely men, because God is an infinite Man, so all animals, plants, and even minerals wear a resemblance to man, and throughout all nature there is an incessant effort to evolve the human form. In the sight of God and the angels, larger and smaller bodies of human beings and the societies of heaven and hell appear organized like men, and Swedenborg calls the universe the Grand Man (*Maximus Homo*). As infinite love was the end and infinite wisdom the cause of creation, so the divine life and power are constantly active in sustaining and directing it. This activity is the Divine Providence, and it reaches to every smallest particular of nature and humanity. Man has freedom, because without it he could not be an adequate recipient of the divine love, and by the abuse of his freedom he has introduced evil into the world. The Divine Providence seeks, without destroying this freedom, to lead man back to his original integrity. Hence all the wonderful dealings of God with man recorded in the Scriptures;

hence the incarnation; and hence the various forms of religion which exist in the world, all of which embody more or less the essentials of salvation, namely, the worship of God and abstinence from evils as sins against him. The smaller treatises of Swedenborg are mostly extracts from his larger works, with amplifications and additions.—The fullest account of him and his writings is that of William White (2 vols., London, 1867, since republished in one volume). See, also, "Documents concerning Swedenborg," by R. L. Tafel (London, 1875 *et seq.*). All of his theological and some of his scientific works have been translated into English. The theological works have also been reprinted in Latin by Dr. J. F. I. Tafel, of Tübingen, Germany, and partially translated and published in French, German, Italian, Danish, and Swedish. Societies for promoting their circulation are in operation both in the United States and in Europe. The principal writers who have undertaken the exposition of Swedenborg's doctrines in England are John Clowes, Robert Hindmarsh, C. A. Tulk, Samuel Noble, J. J. G. Wilkinson, and Jonathan Bayley; in France, E. Richer and J. F. Les Boys-des-Guays; and in the United States, George Bush, Theophilus Parsons, E. H. Sears, Henry James, B. F. Barrett, W. B. Hayden, and Chauncey Giles. For an account of the ecclesiastical organization based upon Swedenborg's doctrines, see New Jerusalem.

**SWEET BRIER.** See Eglantine.

**SWEET GUM.** See Liquidambar.

**SWEET POTATO.** See Potato, Sweet.

**SWEETWATER,** a central county of Wyoming, extending across the territory from Montana on the north to Colorado and Utah on the south; area, about 35,000 sq. m.; pop. in 1870, 1,916. It is crossed by the Wind River and Rocky mountains, and is watered in the north by the Big Horn river and its head streams, and in the south by the Sweetwater and Green rivers. It contains deposits of coal and gold. The S. part is crossed by the Union Pacific railroad. In 1870 there were 3 saw mills and 4 quartz mills. Capital, South Pass City.

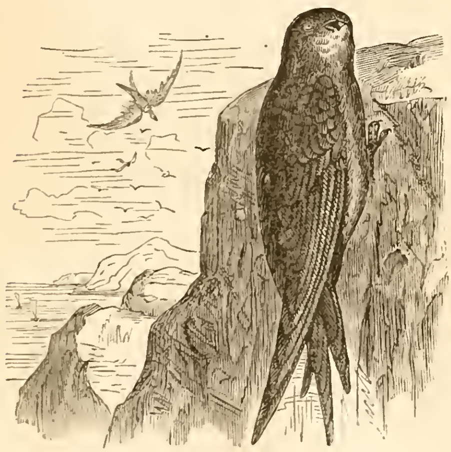
**SWEET WILLIAM.** See Pink.

**SWETCHINE, or Svetchin, Anne Sophie,** a French writer, born in Moscow in 1782, died in Paris, Sept. 10, 1857. She was the granddaughter of Gen. Boltin, a translator of the *Encyclopédie* into Russian, and daughter of Soimonoff, one of the founders of the academy of sciences at Moscow, and private secretary to Catharine II., at whose court she was brought up. In 1799 she married Gen. Svetchin (born in 1758, died Nov. 23, 1850) to please her father, who was banished from St. Petersburg and died soon afterward at Moscow. Her mother having died, the education of her younger sister (the future princess Gregory Gagarin) devolved upon her, in addition to that of her husband's adopted daughter. At the same time she gathered round her the most eminent Russians and French emigrants, who cultivated her society even after the sudden removal in 1801 of her husband from his offices as military commandant and provisional governor of St. Petersburg. Her delicate health and her sorrow for the loss of her father increased her proneness to religious meditation, which was still further developed by her filial relations with the count Joseph de Maistre, French ambassador at the Russian court, although her final conversion in 1815 to Roman Catholicism was more directly ascribed to the writings of the abbé Fleury. As soon as the proscriptive measures against the Jesuits were announced, she publicly avowed her change of religion; and as it was feared that her ascendancy over the emperor Alexander might become as great as that of Mme. Krüdener, she was compelled to depart from Russia by vexatious proceedings against her husband on this and subsequent occasions. She spent the winter of 1816–'17 in Paris. In 1818 she and her husband were at St. Petersburg, and she never returned again to Russia excepting once about 12 years later. After spending several years in Italy, she settled permanently in Paris in 1825. De Falloux, her literary executor, has published *Mme. Swetchine, sa vie et ses œuvres* (2 vols., 1859, vol. ii. comprising her *Pensées*, &c.); her *Lettres* (2 vols., 1862); *Journal de sa conversion* (1863); and *Lettres inédites* (1866). Harriet W. Preston has translated the "Life and Letters of Madame Swetchine" (Boston, 1867; 8th ed., 1875), and "The Writings of Madame Swetchine" (1869). See also Mme. Swetchine's correspondence with Lacordaire (Paris, 1864), and with Lagrange (1875).

**SWIETEN, Gerard van,** a Dutch physician, born in Leyden, May 7, 1700, died in Schönbrunn, Austria, June 18, 1772. He was a favorite pupil of Boerhaave, and after a few years' practice became professor of medicine at Leyden; but on account of his adherence to the Roman Catholic faith he was compelled to resign. In 1745 he went to Vienna as physician-in-chief to the empress Maria Theresa, and professor of medicine and anatomy; and he held several other important offices there. His great medical work, *Commentarii in H. Boerhaavii Aphorismos de Cognoscendis et Curandis Morbis* (5 vols. 4to, Leyden, 1741–'72), was translated into German, English, and French.

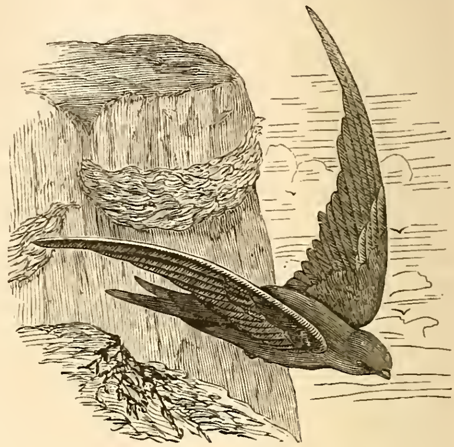
**SWIFT,** the general name of the *cypselidæ*, a subfamily of birds formerly placed among the swallows, but by modern ornithologists ranked as a separate family coming near the humming birds, on account of certain anatomical peculiarities, and particularly of the absence of singing muscles in the lower larynx. The swifts resemble the swallows in habits and in their general form; the bill is more suddenly curved, unprovided with bristles at the base; nostrils very large, oblong, with an elevated margin; wings extremely long, curved and narrow, with ten primaries; tarsi short and weak, and more or less feathered; toes short and thick, and all four are or may be directed forward; claws

strong and curved; ten feathers in the tail. They are very swift and graceful fliers, feeding exclusively on insects, which they capture on the wing; they are migratory like the swallows, but do not mingle with them and are less hardy; most of them nestle in hollow trees, holes in buildings, or crevices in rocks; some species rear two or three broods in a season.—In the genus *cypselus* (Illig.) the second quill is the longest, and the tarsi are feathered to the base of the toes; it is peculiar to the old world. The common European swift or black martin (*C. apus*, Illig.) is $7\frac{1}{2}$ in. long, with a forked tail; it is blackish brown above with a green gloss, and the throat grayish white. It appears in Great Britain in May, departing in August. The extreme shortness of the legs renders walking and rising from a flat surface almost impossible, but the stout toes and sharp claws form admirable clinging organs for climbing in and out the holes where the nests are placed. The white-bellied swift (*C. melba*, Illig.) is $8\frac{1}{2}$ in. long, grayish brown above and white below, the legs covered with brown feathers; it is common in southern Europe, especially in mountainous regions.—In the genus *chætura* (Steph.) or *acanthylis* (Boie) the tail is very short, about two fifths of the wings, slightly rounded, the shafts stiffened and extending beyond the feathers as rigid spines; first quill the longest; legs covered with a naked skin. The species are found in North and South America, Australia, and the East Indies; they live in flocks, and breed usually in holes of trees, but sometimes in crevices



White-bellied Swift (Cypselus melba).

in rocks, and the eggs are usually four. The American swift or chimney swallow (*C. pelagica*, Baird) is $5\frac{1}{4}$ in. long and $12\frac{1}{3}$ in. in alar extent; it is sooty brown above with a greenish tinge, a little paler on the rump, and considerably lighter from the bill to the breast; it is found from the eastern states to the slopes of the Rocky mountains, arriving from the south by the end of April or beginning of May, and departing during the first half of September. This species naturally makes its nest in hollow trees, but in the neighborhood of man builds in such chimneys as are not used in summer for fires; the nest is made of twigs snapped off from a dead tree during flight, fastened together by viscid saliva, without soft



Esculent Swift (Collocalia esculenta).

lining, and is generally placed from 5 to 8 ft. from the entrance; the eggs are pure white. They pass in and out the chimney with great rapidity, making a whirring sound like distant thunder; there are sometimes 200 in a single chimney.—In the genus *collocalia* (Gray) the bill is very small, wings very long, tail moderate and nearly even, and tarsi naked. The esculent swift or swallow (*C.* [*hirundo*] *esculenta*, Gray) is the principal maker of the celebrated nests so highly esteemed by the Chinese as articles of food. (See Birds' Nest, Edible.) The eggs are two in this genus. There are many other species of swifts, both in the old world and the new.

**SWIFT,** a W. county of Minnesota, bordering S. W. on the Minnesota river, and intersected by the Chippewa and Pomme de Terre rivers; area, about 750 sq. m. It has been formed since the census of 1870. The surface is rolling, with numerous small lakes; the soil is good. The St. Paul and Pacific railroad traverses the county. Capital, Benson.

**SWIFT, Jonathan,** a British author, born in Dublin, Nov. 30, 1667, died there, Oct. 19, 1745. He was of purely English descent; his father, dying before the birth of his son, left his family in dependent circumstances. In his 15th year he entered Trinity college, Dublin, where from his insufficiency in some respects he received his bachelor's degree only *speciali gratia*, in February, 1685; but he remained in college studying for a master's degree till the revolution of 1689 drove him to England, where he became private secretary to Sir Wil-

liam Temple, whose wife was related to his mother. He employed his leisure hours in study, and acquired a remarkable familiarity with public affairs. In 1692 Swift took his master's degree at Oxford, and two years later, finding Temple unwilling to make any definite provision for him, he went to Ireland. In October, 1694, he was ordained, and soon after received the prebend of Kilroot, in the diocese of Connor; but in a few months he returned to his secretaryship. Temple, dying in January, 1699, left him a legacy, coupled with the task of editing his posthumous works (London, 1699). Swift next became chaplain to Lord Berkeley, one of the lords justices of Ireland, whom in 1699 he accompanied to Dublin, acting as his secretary during the journey. He was supplanted in the secretaryship by a person who subsequently interfered so that the rich deanery of Derry, at Berkeley's disposal, and to which Swift deemed himself entitled, was given to another. Swift exclaimed to the earl and his secretary, "Confound you both for a couple of scoundrels!" and left the castle. But he soon came back, the new dean of Derry (Dr. Bolton) being required to resign to him the vicarage of Laracor and several other livings, amounting altogether to nearly £400 a year. In 1700 Swift assumed his parochial duties at Laracor, and shortly after received the prebend of Dunlavin in St. Patrick's cathedral, Dublin, and in February following took his doctor's degree in Dublin university. In 1701 he made the first of a number of annual visits to England, and published anonymously in London his "Discourse on the Contests and Dissensions between the Nobles and Commons of Athens and Rome," vindicating the conduct of the whig leaders, Somers, Halifax, Harley, and Portland, in respect to the partition treaty. It was generally attributed to Somers himself or Burnet; but Swift avowed the authorship in the succeeding year, and was immediately admitted into the society of the statesmen he had defended, and into that of Addison, Steele, Arbuthnot, and others of the leading wits of the time. Some trifles in prose and verse had shown an original vein of humor, but he had signally failed in a series of "Pindaric Odes." In 1704 appeared his "Battle of the Books," written at Moor Park in 1697, in support of Sir William Temple's views in the controversy respecting the relative merits of ancient and modern learning. This was succeeded by the "Tale of a Tub," a satire upon the Roman Catholics and dissenters. It is one of Swift's most perfect and labored efforts, but its imputed irreligious tendency proved an insurmountable obstacle to his hopes of high preferment. In 1708 he published his "Argument to prove the Inconvenience of Abolishing Christianity," a masterpiece of grave irony; "Sentiments of a Church of England Man with respect to Religion and Government;" the humorous attacks on Partridge the almanac maker, entitled "Predictions for 1708, by Isaac Bickerstaff;" and "Letters on the Sacramental Test," in which he differed with the whigs, and this may partially explain his subsequent abandonment of that party. In 1709 he published the only work to which he ever attached his name, "A Project for the Advancement of Religion and the Reformation of Manners." Failing to receive preferment from the whigs, he went over to the tories in October, 1710; and for several months the "Examiner," a weekly paper established by St. John and others in the interest of the ministry, was the vehicle for bitter attacks from his pen upon prominent whig statesmen. About this time he formed the society of Brothers, composed of 16 influential tories, of which he was the most active member. His powerful pamphlet on the "Conduct of the Allies," published in November, 1711, which had a considerable influence in bringing the war to a close, raised his reputation to the highest pitch, and he found himself in a position to confer substantial favors. But he himself, while dictating, as Dr. Johnson has observed, the political opinions of the English nation, remained unrewarded; and the efforts of Harley and St. John, now become Lords Oxford and Bolingbroke, aided by Mrs. Masham, were unavailing to procure him a bishopric, the queen, under the advice of Archbishop Sharp and other prelates, positively refusing him any high preferment. On the failure of an application in his behalf for the vacant see of Hereford, through the opposition of the duchess of Somerset, whom he had lampooned, Swift threatened to withdraw his support from the ministry, but was pacified by his appointment, in February, 1713, to the deanery of St. Patrick's cathedral, Dublin, the income of which amounted to £700. He had scarcely got settled in his deanery when he was summoned back to England to reconcile the difficulties between Oxford and Bolingbroke. About this time he wrote his "Public Spirit of the Whigs," which reflected so bitterly upon the Scottish nation and nobility that the latter in a body presented a complaint to the queen. In June, 1714, appeared his "Free Thoughts on the State of Public Affairs;" and on the dismissal of Oxford a few weeks later he declined the flattering overtures of Bolingbroke, in order to be of service to the disgraced minister. The death of the queen immediately after this event and the overthrow of the tories sent Swift back to Ireland, where he remained during the next 12 years.—Swift's history was painfully involved with that of three young ladies. One was Miss Jane Waring, sister of a college friend, of whom he became enamored in Belfast; he called her Varina. His offer of marriage she at first declined on account of her own ill health and his insufficient income; and the hopelessness of settling differences on both sides led to a cessation of their intercourse. While secretary for Sir William Temple, Swift had con-

ceived a strong friendship for Esther Johnson, daughter of a woman who was for many years an attendant upon Temple's sister, Lady Giffard. Swift's account of Esther is that "her father was a younger brother of a good family in Nottinghamshire, her mother of a lower degree." Swift on his first settlement in Ireland invited this young lady (named Stella in his poems) to Laracor, and with a friend, Mrs. Dingley, she came and resided near him. They were intimate, saw each other often, and corresponded when apart; and she attended to his household in his absence. Subsequently, in London, he became acquainted with Hester Vanhomrigh, a spirited, intelligent, and accomplished girl, whom he kindly noticed and aided in her studies. She conceived for him a passion so earnest that she proposed marriage, which he declined, but without discouraging her advances; and after the death of her mother she went to Ireland (1714) to dwell in his vicinity. Vanessa (the name he gave her), ignorant for a time of his relations to Stella, endured his coldness with hope of a favorable change, till in 1717 she retired with her sister to Marley abbey to live in deep seclusion. Meantime Stella urged her claims, and won his consent under the stipulation of perpetual secrecy; and they were married privately in the garden of the deanery in 1716. Their relations had been, and because of this secrecy continued to be, equivocal. Vanessa's sister being ill, Swift several times visited the abbey; but receiving no other encouragement, and tormented by suspicion and impatience, Vanessa wrote to Stella to ascertain the nature of her intimacy with Swift. The dean, getting possession of the letter, rode directly to Marley abbey, flung it upon the table before Vanessa with a frown which struck her dumb with terror, and instantly departed. The unhappy woman survived this shock but a few weeks, and Swift, overcome by shame and remorse, retired for two months to solitude in the south of Ireland. After her death appeared his poem "Cadenus and Vanessa," describing the manner in which Swift (personified as Cadenus, an anagram of *Decanus*, the dean) received the early advances of Miss Vanhomrigh. Five years later Stella herself died, without any public recognition of her marriage.—Swift produced in 1720 "A Defence of English Commodities, being an Answer to the Proposal for the Universal Use of Irish Manufactures," followed in 1724 by the celebrated "Drapier's Letters," in opposition to the royal grant authorizing Wood to coin £108,000 in halfpence and farthings for general circulation in Ireland. The author denounced the whole system of government in Ireland with a vigor and point which aroused a powerful popular feeling in his favor. His effigy was produced on signs and medals, and distributed broadcast in innumerable prints; and so powerful became his influence with the lower classes that Walpole, when meditating legal proceedings against him, was told that it would require 10,000 men to arrest him. In 1726 appeared his "Gulliver's Travels," a series of satires on human nature and society, the most original and extraordinary of all his productions, and that by which he will be known while the language lasts. In 1726 and 1727 he made visits to England, renewing his intimacy with Pope, Gay, Bolingbroke, Arbuthnot, and others of his early friends; but after the death of Stella he never left Ireland. For several years he wrote with vigor and increasing bitterness on Irish affairs, and amused himself with composing verses, the humor of which is more than equalled by the fierceness and obscenity of the satire; but by 1736 his health became so undermined by frequently recurring attacks of deafness and vertigo, to which he had been subject from an early age, as to preclude further literary labors. His infirmities rapidly increased after this, and in a corresponding degree his memory and intellect decayed. In the latter part of 1740 his memory almost entirely left him, and frequent fits of passion at length terminated in furious lunacy. This subsided in 1742, and he passed the last three years of his life in a condition of speechless torpor. He was interred in the cathedral, amid extravagant demonstrations of popular respect. He bequeathed the bulk of his property, amounting to £10,000, to found a hospital for insane persons. Swift was tall and well made, with a swarthy complexion, and a cast of face that would have been heavy but for the pleasing expression of his eyes.—Some posthumous works of Swift were published long after his death, including "A History of the four last Years of Queen Anne;" "Polite Conversation," a satire on the frivolities of fashionable life; and "Directions for Servants." A complete edition of his writings was published in 19 vols. by Sir Walter Scott, whose biography of him is still the standard one. That by Dr. Johnson, in his "Lives of the Poets," reflects too closely the dislike which the biographer always entertained for Swift. There is also a copious life by Thomas Sheridan, and an account of his latter years by Dr. Wilde of Dublin, written on the occasion of the remains of Swift and Stella being exhumed, during some repairs in St. Patrick's cathedral, in 1835. The character of Swift is the subject of an elaborate essay by Thackeray, included in his "British Humorists." John Forster's "Life of Jonathan Swift" (vol. i., 1875) was unfinished at his death.

**SWIFT, Lewis.** See p. 904.

**SWIMMING,** the art of keeping the body afloat and propelling it by means of the hands and feet. The swimming of man is artificial, but as the specific gravity of the human body is very little greater than that of water, it can be floated with little difficulty. The support is greatly increased by propulsion, just as a thin flat stone is prevented from sinking by

projecting it with force against the surface of the water. In learning to swim, the first essential is confidence; the pupil then learns to keep the body afloat; and when he knows how to apply the extremities to the water with a view to propulsion he can swim. Confidence is best assured in this way: Let the pupil wade out breast deep, face about, and toss an egg or a white pebble into the water between himself and the shore and plunge after it. In struggling to reach it he will find himself buoyed up by the water, and will learn that it is easier to swim than to sink. This was Dr. Franklin's suggestion, and the most recent manuals recommend it. Some teachers inspire confidence and at the same time teach the propulsory movements by holding the pupil on the flat of the hand and then removing the support, leaving him to float and propel himself. The use of corks, bladders, and life preservers retards instruction, and is now nearly obsolete. The pupil learns first to swim on the chest. He assumes as nearly as he can a horizontal position, with the breast prone to the water and the heels as near as possible to the surface. To effect propulsion, the arms and legs are simultaneously flexed and drawn slowly toward the body, and then are simultaneously and rapidly extended. The two hands should be kept flat, the fingers closed, the thumb placed by the side of the first finger, and the pupil should reach forward with his hands as far as he can, for the farther forward he reaches the faster will he swim. He then draws both legs well up, and while each hand is brought around, one to the right and the other to the left, he strikes out simultaneously and strongly with his legs. The secret of a good stroke is to kick out with the legs wide apart. The propelling power is secured by the legs being brought from a position in which they are placed wide apart to one in which they are close together like the blades of a pair of scissors. In this position the heels should touch each other, and in drawing up the legs the toes should be pointed backward to avoid the resistance of the water against the insteps. It is a fallacy to suppose that the speed of the swimmer in any degree depends upon the resistance of the water against the soles, or that large flat feet are aids, unless it may be in treading water. Breast swimming is the commonest and easiest method, and the only one possible for long distances. But the prone position of the body presents a large resisting surface; the arms and legs are spread out on either side of the trunk, and so are applied but partially as propellers, the most effective part of the stroke corresponding say to a quarter of an ellipse, while the remaining three quarters are devoted to getting the arms and legs into position, which wastes power and increases friction. To obviate these difficulties, scientific swimmers have recently adopted the side stroke. The swimmer throws himself on the left side (a good swimmer on either side), and advances the left arm in a curve, making it act as a cutwater, while the right arm directed downward and backward and the legs make a powerful stroke. The right arm and legs thus give three limbs moving simultaneously in the same direction, the left arm always moving in an opposite direction. The right arm and legs are flexed and carried forward while the left arm is forced backward, and *vice versa*. The strong backward stroke of the three limbs gives a powerful forward impulse, and as the body is on the side, as on a keel, the resistance is much reduced. The overhand stroke is similar, only in reaching forward the arm is brought out of the water, and the swimmer, advancing the right and left sides of the body alternately, secures greater continuity of motion and materially reduces the friction. Both these methods are much faster but more exhausting than breast swimming, and are practicable only for short distances, in saving life and in races. The speed attained by these strokes is indicated by the recent record of professional swimmers in London; in baths 400 yards have been swum in 5 m. 10 sec., 500 in 7 m. 27 sec., and 1,000 in the Serpentine in 16 m. 43 sec. With a strong favoring tide in the Thames a mile has been swum in 11 m. 43 sec., two in 23 m. 13 sec., three in 35 m. 23 sec., four in 48 m. 19 sec., and five in 64 m. 23 sec. Swimming on the back is more easily learned than breast swimming, and the body being more nearly horizontal, it is not difficult to swim by using the legs only, with the arms folded over the chest. In treading water, the swimmer's body is in an upright position, with the head well out, and a rapid movement of the feet as in ascending steps is the sustaining and propelling power; the hands may be out of the water or may be used to assist in propulsion. Both these methods are reliefs in long swims. In diving, the hands are brought together in front to cleave the water and protect the head, and the legs are kept straight, the heels touching each other. If the diver desires to come almost instantly to the surface again, he has only to direct his hands upward above his head. To float on the back, the swimmer suffers the back of the head to be submerged, the face only being above water; the hands are extended and the legs partially flexed and spread so as to offer the greatest possible floating surface. In attempting to save a drowning person, the swimmer should approach him from behind, and keep him from sinking by raising him by the hair, or by placing the hands under his armpits, taking care that the struggler does not seize him, or both may be drowned. An exhausted or cramped swimmer may be supported by placing his hand on the shoulder of another swimmer. As salt water is more buoyant than fresh, it is easier to swim in it. The best time for the exercise is in the forenoon between breakfast and luncheon, when the stomach is neither full nor empty. For swimming matches the training

is like that for any other exercise, which, according to Capt. Webb, the channel champion, "simply means a healthy life."—In ancient times Leander, according to Greek tradition, swam the Hellespont from Abydos to Sestos; and on March 3, 1810, Lord Byron and Lieut. Eckenhead swam over the same course in 70 minutes, which till recently has been regarded as the greatest feat of the kind in modern times. In 1849 John Leahy, then a British soldier in quarters at Aden, and since 1868 teacher of swimming at Eton college, swam in the Red sea 2½ m. in three quarters of an hour. In August, 1868, Harry Parker swam in the Serpentine 500 yards in 7 m. 45 sec. On Aug. 5, 1872, in the lake at Hendon, near London, J. B. Johnson swam a mile in 26 minutes, doing the first half mile in 12 minutes. In 1874 Matthew Webb, then 26 years old, swam out as far as Varne buoy, 10 m. off Folkestone, and was in the water 4½ hours. The year 1875 is memorable for extraordinary swimming feats. On April 10 Paul Boyton of New Jersey attempted to cross the English channel from Dover in a swimming costume invented by Capt. C. S. Merriman of New York. He was in the water nearly three hours, propelling himself with a paddle having a blade at each end, accomplishing as the tide and waves carried him about 27 m.; and after tossing about three hours more in the surf, he was taken on board a steamer. On May 29 he successfully crossed from Cape Gris Nez to South Foreland, 3 m. from Dover, by his course about 36 m., in 23 hours. These were hardly swimming feats, but the usefulness of the costume and means of propulsion in saving life and property on the water was fully demonstrated. On July 3 Webb swam from Blackwall pier to Gravesend, 20 m., in 4 h. 42 m. 44 sec. On July 23, at Chester, Pa., in a match with Coyle, J. B. Johnson swam 10½ m. in 3 h. 10 m. On Aug. 12 Webb made his first attempt to cross the channel. He swam out from Dover 18½ m. in 6 h. 45 m., when on account of the roughness of the sea he was taken on board a lugger. On Aug. 24–25 he successfully crossed from Dover to Calais, the tide making his course a zigzag of about 50 m., in a little less than 22 h. He had no other covering than a coating of porpoise oil, and received no refreshment but hot coffee, beef tea, cod-liver oil, and an occasional sip of brandy, which he took while treading water. On Sept. 1 Agnes Beckwith, 14 years old, daughter of a teacher of swimming, swam from London bridge to Greenwich pier, about 5 m., in 1 h. 7 m. 45 sec. On Sept. 4 Emily Parker, 14 years and 6 months old, sister and pupil of Harry Parker, the champion swimmer of London, swam the same distance in 1 h. 8 m.—Illustrated treatises on swimming with instructions may be found in Walker's "British Manly Exercises" (London, 1844; latest ed., 1874), and in "Animal Locomotion, or Walking, Swimming, and Flying," by J. Bell Pettigrew (London and New York, 1875). Sergeant Leahy has published "The Art of Swimming in the Eton Style," with a preface by Mrs. Oliphant (Norwich, 1875), and Capt. Webb "The Art of Swimming," edited by A. G. Payne (London, 1875).

**SWINBURNE, Algernon Charles,** an English poet, born in London, April 5, 1837. He is a son of Admiral Charles Henry Swinburne. After studying in France, he entered Balliol college, Oxford, in 1857, but left the university without graduating. He has published "The Queen Mother" and "Rosamond," two plays (1860); "Atalanta in Calydon," a tragedy in the Greek form (1864); "Chastelard, a Tragedy" (1865); "Poems and Ballads" (1866; republished in New York under the title "Laus Veneris"), which was soon suppressed by the publisher; "Notes on Poems and Reviews" (1866), a reply to his critics; "A Song of Italy" (1867); "William Blake, a Critical Essay" (1868); "Notes on the Royal Academy Exhibition" (1868), with W. M. Rossetti; "Siena, a Poem" (1868); "Ode on the Proclamation of the French Republic" (1870); "Bothwell, a Tragedy" (1870); "Songs before Sunrise" (1871); "Essays and Studies" (1875); "George Chapman, a Critical Essay" (1875); and "Erechtheus," a play on the Greek model (1875). He has edited "Christabel, and the Lyrical and Imaginative Poems of S. T. Coleridge" (1869), and Chapman's works (1875).

**SWINE.** See Hog.

**SWING, David.** See p. 905.

**SWITZERLAND** (Lat. *Helvetia;* Ger. *Schweiz;* Fr. *La Suisse*), a federal republic of central Europe, between lat. 45° 50′ and 47° 50′ N., and lon. 5° 55′ and 10° 30′ E. It is bounded N. by Germany, E. by Austria and Liechtenstein, S. by Italy and France, and W. by France; and nearly the entire boundary line is formed by rivers (the Rhine and Doubs), lakes (of Constance and Geneva), and mountains (the Alps and Jura). In its greatest length it measures 210 m.; in its greatest breadth, 140 m. Switzerland is the most mountainous region of Europe, and, with Tyrol and Savoy, which border it on the east and southwest respectively, the most elevated. Even the most level part in the north presents mountains rising upward of 2,000 ft. It is covered throughout almost its whole extent by the Alps, of which the following groups, with their various branches, belong properly to Switzerland: 1, the Pennine Alps, separating the canton of Valais from upper Savoy on one side and Piedmont on the other; 2, the Lepontine or Helvetian Alps, including the divergent Bernese Alps, extending on both sides of the Rhône, and separating Switzerland from Lombardy; 3, the Rhætian Alps, beginning at Monte Bernardino and extending along the frontiers of Switzerland, Italy, and Tyrol. (See Alps.) The principal Alpine summits in Switzerland, such as the Monte Rosa, Matterhorn or Mont Cervin, Finsteraarhorn, and Jungfrau, ranging between 15,200 and 13,700 ft., are treated separately

under their respective names. To the west of the Alps, between France and Switzerland, extends the Jura range of mountains. (See Jura.) There are many points of view whence the semicircular array of peaks, presented at once to the eye, extends for more than 120 m., and comprises between 200 and 300 distinct summits, capped with snow or bristling with bare rocks. Of the heights commanding such panoramas, the Rigi is probably the finest and is one of the most accessible. (See Rigi.) The Faulhorn, in the Bernese Oberland, affords a fine view of the High Alps rising close at hand. For a near view of Alpine scenery, among the spots which afford a concentration of the grandest objects are the valleys of the Bernese Oberland, and those which descend from Monte Rosa in Valais. In these districts the glaciers are seen to great advantage. A description of the Swiss Alpine passes, the carriage roads, including those recently opened, and the railway over the St. Gothard pass now (1876) in course of construction, is given in Alps. Of the Alpine defiles, the ravine of the Via Mala, on the upper Rhine in Grisons, is one of the most sublime scenes. The gorge of the Schöllenen on the St. Gothard, that of Gondo on the Simplon, and the glen in whose depths the baths of Pfäfers are sunk, also deserve mention. The glaciers of Switzerland are the reservoirs which feed some of the largest rivers of western Europe, including the upper Rhine, which flows within and along the boundary line of Switzerland, and then enters Germany, and the Rhône, which rises among the glaciers of the St. Gothard range near the Furca, receives the Visp, Borgne, and Dranse, and on quitting the canton of Geneva becomes a French river. The next largest river in Switzerland is the Aar, which rises in the Bernese mountains, receives the Saane, Reuss, and other affluents, and carries the waters of 14 cantons to the Rhine. The Ticino flows through the canton of that name, and passes through Lago Maggiore into Italy; and the Inn waters a part of the canton of Grisons. There are numerous waterfalls, among which are the fall of the Aar, at Handeck, in the canton of Bern; the Staubbach or Dust fall, in the Bernese Oberland; the Giesbach, on the lake of Brienz; the fall of the Sallenche, known as the Pissevache, near Martigny, Valais; Reichenbach falls, near Meiringen, Bern; the fall of Pianazzo, on the Splügen, Grisons; the Tourtemagne fall, near the Simplon road, in Valais; and the falls of the Rhine, near Schaffhausen. There are several lakes, and the more important, Bienne, Constance, Geneva, Lago Maggiore, Lucerne, and Lugano, are described in separate articles.—The more marked geological features of Switzerland are noticed in the articles Alps and Jura; and the glacial phenomena which have been most carefully studied, and which throw so much light upon the dynamics of geology, are specially treated in the article Glacier. No country possesses greater interest for geologists than Switzerland, whose formations are exhibited upon the grandest scale, and reveal in the most striking manner the metamorphism to which rocks are subject, converting strata of comparatively recent formation into schistose and crystalline rocks; but its mineral resources, including iron, lead, and copper, are of no great importance. Anthracite of inferior quality is found in several places. The salt mines near Basel and those at Bex (Vaud) are the most important. Gypsum is found with the salt, and slate is extensively quarried. There is a large number of mineral springs, many of which are famous as watering places. The most celebrated are Leuk (Valais), St. Moritz in the valley of Engadine (Grisons), Pfäfers (St. Gall), and Baden and Schinznach (Aargau).—The climate is more severe than might be expected from the geographical position of Switzerland. On the highest summits snow and ice are perpetual. On the lower mountains and the table land snow falls in greater abundance than in other countries of the same latitude in Europe. In Valais the fig and grape ripen at the foot of ice-clad mountains, while near their summits the rhododendron and the lichen grow at the limit of the snow line. Ticino has the climate of Italy, yet the weather is more changeable. Switzerland on the whole is very healthful, with the exception of a few places in swampy or very narrow and deep valleys. In the middle ages the country of the Jura suffered much from earthquakes, which have entirely ceased for several centuries; but floods, avalanches, and snow storms still threaten the inhabitants with frequent dangers. About two thirds of the surface consists of lakes and other waters, glaciers, naked rocks, and other uninhabitable heights. Some districts are very fruitful, yet the grain raised is not sufficient for the supply of the population. The vine is cultivated on the slopes of the Jura and in the valleys of the Rhine, Rhône, Reuss, Limmat, and Thur, and in some places ripens at 2,000 ft. above the sea. The annual production is valued at about $6,000,000. Flax and hemp are extensively grown. Irrigation is judiciously managed, and in general agriculture is making progress. The forests cover about 17 per cent. of the soil, and although their cultivation is imperfect, the production of timber exceeds the home consumption. Fishing still yields considerable produce, but hunting is not practised to the same extent as formerly, and in some of the cantons it is forbidden by law. Chamois are still found in the Alps; other animals are bears, wolves, wild boars, and roebucks; foxes and hares are numerous, and otters are found in some of the lakes. Switzerland is celebrated for its rich and excellent pastures; the finest breeds of cattle are those of the Simmenthal and Saanen (Bern), Gruyère (Fribourg), Zug, and Schwytz. In 1866 there were 993,000 horned cattle (about one fourth milch cows), 100,000 horses, 447,000 sheep, 375,000 goats, and 304,000 swine.

The sheep and swine do not supply the home demand. The best cheese is made in Gruyère and in Urseren (Uri), and in the valleys of the Emmen, Saane, and Simmen.—While Switzerland is mainly agricultural, certain classes of manufactures are prosperous and important. The chief seats of the cotton manufacture are Aargau, Appenzell, St. Gall, Zug, and Zürich. The number of mills in 1870 was 168, and of spindles 2,059,350, employing 20,000 operatives, besides 38,000 hand-loom weavers. This estimate includes 6,000 workers in Appenzell and St. Gall employed in the manufacture of embroidery alone, to the annual value of $2,000,000. Basel employs 6,000 persons in the manufacture of silk ribbons, to the annual value of $7,000,000, and 12,000 operatives in Zürich make silk stuffs of the annual value of $8,000,000. In Bern, Geneva, Neufchâtel, Solothurn, and Vaud 36,000 persons produce annually 1,600,000 watches, valued at $17,600,000. The movements of many of these are exported to be cased in other countries. Wood carving is carried on in most of the cantons. Vaud produces annually 80,000 musical boxes. The exports of Switzerland to the United States for the year ending Sept. 30, 1874, amounted to $12,270,368, including watches to the value of $2,423,993. The value of the foreign trade in 1868 was set down at $93,600,000 of exports and $84,000,000 of imports. The principal articles of import are grain, flour, wine and cider, iron, raw cotton, coal, and petroleum. The aggregate length of railway lines, Jan. 1, 1874, was 916 m. They are all private roads, with the exception of the Bern railway, which belongs to the state. The aggregate length of telegraph in 1873 was 6,322 m., with 715 stations.—Switzerland consists of 22 cantons, or, as three cantons, Unterwalden, Appenzell, and Basel, are divided into two independent half cantons each, of 25 states, the area and population of which are as follows:

| CANTONS. | Area in sq. m. | Population in 1870. | Catholics. | Protestants. |
|---|---|---|---|---|
| Aargau | 542 | 198,873 | 89,180 | 107,703 |
| Appenzell Outer Rhodes | 100 | 48,726 | 2,358 | 46,175 |
| Appenzell Inner Rhodes | 63 | 11,913 | 11,720 | 188 |
| Basel City | 14 | 47,760 | 12,301 | 34,455 |
| Basel Country | 162 | 54,127 | 10,245 | 43,523 |
| Bern | 2,660 | 506,561 | 66,015 | 436,304 |
| Fribourg | 643 | 110,832 | 93,951 | 16,819 |
| Geneva | 109 | 93,239 | 47,868 | 43,639 |
| Glarus | 267 | 35,150 | 6,888 | 28,238 |
| Grisons | 2,774 | 91,782 | 39,843 | 51,887 |
| Lucerne | 579 | 132,338 | 128,338 | 3,823 |
| Neufchâtel | 312 | 97,284 | 11,590 | 84,334 |
| St. Gall | 780 | 191,015 | 116,060 | 74,573 |
| Schaffhausen | 116 | 37,721 | 3,051 | 34,466 |
| Schwytz | 359 | 47,705 | 47,047 | 647 |
| Solothurn | 303 | 74,713 | 62,078 | 12,448 |
| Thurgau | 382 | 93,300 | 23,454 | 69,231 |
| Ticino | 1,095 | 119,619 | 119,350 | 194 |
| Unterwalden, Upper | 183 | 14,415 | 14,055 | 358 |
| Unterwalden, Lower | 112 | 11,701 | 11,632 | 66 |
| Uri | 415 | 16,107 | 16,018 | 80 |
| Valais | 2,026 | 96,887 | 95,963 | 900 |
| Vaud | 1,244 | 231,700 | 17,592 | 211,686 |
| Zug | 92 | 20,993 | 20,082 | 878 |
| Zürich | 665 | 284,786 | 17,942 | 263,730 |
| Total | 15,988 | 2,669,247 | 1,084,525 | 1,566,345 |

Fourteen of these divisions have capitals of the same names; those of the remaining eleven are as follows: Aargau, Aarau; Appenzell Outer Rhodes, Trogen and Herisau, alternating; Basel Country, Liestal; Grisons, Coire; Thurgau, Frauenfeld; Ticino, Lugano, Locarno, and Bellinzona, alternating; Upper Unterwalden, Sarnen; Lower Unterwalden, Stanz; Uri, Altorf; Valais, Sion; Vaud, Lausanne. Of the entire population 94·3 per cent. were natives, and 5·7 foreigners, including 63,000 Germans, 62,000 French, and 18,000 Italians. The number of communes in 1870 was 3,052, of which 5 had a population of more than 20,000, 7 from 10,000 to 20,000, 31 from 5,000 to 10,000, and 251 more than 2,000. The number of houses was 387,148, and of families 557,018. The excess of females over males was about 59,500. The number of births in 1871 was 81,629, and of deaths 77,998. The population has increased since 1816 about 50 per cent., more slowly than that of the United States and Great Britain, but in a much larger ratio than that of France. Geneva, Basel, and Neufchâtel have increased nearly 100 per cent.; Lucerne and Bern more than 50; Zürich nearly 50. Since 1860 every canton except Appenzell Inner Rhodes shows an increase of population. Of the entire population in 1870, 1,095,447 were wholly or partly supported by agriculture; the manufactories employed 216,468, and the handicrafts 241,425. The difference of language points to the difference of origin of the inhabitants of the several cantons. The N., N. E., and central cantons speak a German dialect; French prevails in Vaud, Geneva, and Neufchâtel, and in parts of Valais, Fribourg, and Bern; Italian in Ticino and in a part of Grisons; and Romansh, a corrupted dialect of the Latin, in a part of Grisons. The population speaking these four languages is classified by the census of 1870 as follows: German is spoken in 384,538 families, French in 133,575, Italian in 30,079, Romansh in 8,778, and other languages in 48. A majority of the inhabitants are Protestants, but the Roman Catholics are most numerous in 11 cantons and one half canton, viz.: Appenzell Inner Rhodes, Fribourg, Geneva, Lucerne, St. Gall, Schwytz, Solothurn, Ticino, Unterwalden, Uri, Valais, and Zug. They have five bishops, viz.: of Basel, Coire, Fribourg, St. Gall, and Sion. There are also priests with the functions of prefects apostolic to minister to scattered Catholics. In 1872 the pope erected Geneva into a new diocese, but the cantonal government denounced the measure as contrary to law. In 1873 the pope made it an independent vicariate apostolic, and the bishop of Fribourg resumed the former additional title of Lausanne, but the federal council refused to recognize it. In 1873–'4 several parish churches, especially in the cantons of Aargau, Bern, Geneva, and Solothurn, passed into the possession of the Old Catholics. The Jesuits and Redemptorists are excluded by the federal con-

stitution from Switzerland, and the number of the convents of other religious orders has been somewhat reduced during the present century; in 1874 it amounted to 88. The constitution of 1874 forbids the founding of new convents. The Protestants belong mostly to the Reformed church. Since 1857 deputies of the Reformed cantonal churches meet annually in a Helvetic conference. Faculties of Protestant theology are connected with the universities of Bern, Zürich, and Basel, and there are also several theological schools in French Switzerland; in Bern a faculty of Old Catholic theology was established in 1874. Basel is the seat of the greatest missionary and Bible society of continental Europe, while the religious societies of French Switzerland have their centre in Geneva. Free churches (Presbyterian or Independent) have been formed during the present century by secession from the state churches, and are especially numerous in the cantons of Geneva, Neufchâtel, and Vaud, in each of which they have a theological school. The Methodists and Baptists have congregations in several cantons, and the former also a book concern at Zürich. In 1870 the number of Jews amounted to 6,996.—Switzerland has three full universities, at Basel, Bern, and Zürich. The former was founded in 1460, the two latter since 1832. All are organized after the model of the German universities, governed by a rector and a senate, and divided into faculties, of which Basel has four, Zürich five, and Bern six. There are also four academies, at Geneva, Lausanne, and Neufchâtel, each with three faculties, and Fribourg with two faculties; three lyceums, at Lugano, Einsiedeln (Schwytz), and Sion; and nine theological schools. The academy at Geneva (called also university), founded in 1368, the scene of Calvin's and Beza's teaching, has hitherto lacked a medical faculty. This will soon be added, completing the university. All the academies except that of Fribourg are Protestant, all the lyceums Catholic. The number of gymnasia and cantonal schools is 47. The federal constitution of 1848 provided for the establishment of a federal university (the three above mentioned being cantonal institutions); but the conflicting claims of several cantons as to its location, and of the Reformed and Roman Catholic churches as to its organization, have prevented the execution of the plan. A federal polytechnic school was founded in 1854 at Zürich, and has attained a high degree of prosperity and celebrity. In 1874 it had 73 professors and 676 students, and 275 pupils who study one or more branches at their option. The number of public schools amounts to about 7,000, educating upward of 400,000 pupils. There is a federal military academy at Thun (Bern). The expenses of public instruction are partly paid by the communities, partly by special school funds, and partly by appropriations of the cantonal governments; and the constitution requires that all children must attend school from their 7th to their 14th year. Many private educational institutions have gained a world-wide celebrity since the days of Pestalozzi and Fellenberg, who conducted establishments of this kind at Yverdun (Vaud) and Hofwyl (Bern). Considerable attention is given to musical instruction, and in 1874 the federal singing societies numbered 8,552 members. The Alpine valleys are remarkable for their peculiar local melodies. (See Ranz des Vaches.) The number of periodicals published in Switzerland in 1872 was 412, of which 266 were in German, 118 in French, 16 in Italian, 5 in Romansh, 1 in English, and 6 in German and French. The aggregate number of copies issued was 90,800,000.—The first federal constitution of Switzerland, which superseded the federal contract of Aug. 7, 1815, and changed the federal union of states into a federal republic, was promulgated Sept. 12, 1848. A revised constitution was submitted to the people on April 19, 1874, and, having received the constitutional majority, came into force on May 29. It provides that all the rights of sovereignty which are not expressly transferred to the confederacy are exercised by the 25 cantons and half cantons. Among the prerogatives of the federal government are the rights of declaring war, of concluding peace or treaties, and of sending diplomatic representatives. The formation of separate alliances between the cantons, without special permission, is prohibited. The constitution of every canton is guaranteed, if it is republican in form, if it has been adopted by the people, and if it can be revised on the demand of a majority of the citizens. All Swiss are equal before the law, and the former relation of subjects as well as all privileges of place or birth are abolished. There shall be complete and absolute liberty of conscience and of creed. No one can incur any penalties whatsoever on account of his religious opinions. The father or guardian has the right to dispose of the religious education of the children up to the age of 16 years. No one is bound to contribute to the expenses of a church to which he does not belong. The free exercise of worship is guaranteed. Civil marriage is compulsory, and a subsequent religious ceremony is optional. The cantons have the right to maintain peace and order between different religious communities, and to prevent encroachments of ecclesiastical authorities upon the rights of citizens. No new bishoprics can be created without the approbation of the federal government. Liberty of the press, of petition, and of association is guaranteed; but the Jesuits and all religious orders and associations which are affiliated to them are prohibited; all functions, clerical and scholastic, are forbidden to Jesuits, and this interdiction can be extended to any other religious order whose action may be deemed dangerous to the state. The confederacy has the right of sending away dangerous foreign-

ers. The legislative power is vested in the federal assembly, which consists of a national council and a council of states (Ger. *Ständerath;* Fr. *conseil des états*). The national council consists of deputies of the people, in the ratio of about one for every 20,000 persons, so that every canton and every independent half canton has the right of electing at least one councillor. On the basis of the census of 1870 the council consists of 135 members. The national council is elected for the term of three years, and every citizen who is 20 years of age has the right of voting, and any voter, not a clergyman, is eligible. Naturalized citizens may be elected after being citizens for five years. The council of states has 44 members, two for every canton and one for every half canton. The members of the national council are paid out of the federal treasury, those of the council of states by the cantons. The executive power is exercised by a federal council, consisting of seven members, who are chosen for a term of three years by the federal assembly (the national council and the council of states in joint session). They divide among themselves the seven departments of foreign affairs, of the post and telegraphs, of justice and police, of finance, of war, of the interior, and of commerce and duties, each member taking one department and being at the same time the substitute in a second department. The president and vice president of the federal council, who are also president and vice president of the confederation, are chosen for one year only, and by the council itself from among its own members, and are not reëligible till after the expiration of another year. The federal court, which is also chosen by the federal assembly for a term of six years, consists of nine members and nine substitutes, and has its seat at Lausanne. The constitution may at any time undergo a revision in the regular way of legislation; if the two councils disagree, or if 50,000 citizens demand it, the question of a revision has to be submitted to a direct vote of the people. The revised constitution, in order to become effective, must be adopted by a majority of all citizens of Switzerland as well as by a majority of the cantons. The cantonal constitutions may be divided into two classes: 1. Pure democracies, in which the rights of sovereignty are exercised by a general assembly of all citizens, which meets once a year, mostly in April or May, votes upon laws, fixes the taxes, and elects the cantonal officers. The executive is called *Landrath*, and consists of the cantonal officers and the councillors elected by the several political communities. This is the constitution of Uri, Appenzell, Unterwalden, and Glarus. 2. Representative democracies, in which the people elect a legislative assembly, called the grand council, which chooses from its own number the executive, called little council. In many cantons the people have the right of vetoing every bill passed by the grand council. In most of the cantons the members of the grand council receive no pay. Instead of printed law books, some of the smaller cantons used until recently written traditions; but now nearly every canton has its printed code of laws. Many old Germanic elements are to be found in Swiss law; the Roman law has had a predominating influence only in a few border cantons. The institution of the jury, which was first tried in Geneva, has since been introduced into several other cantons. The federal capital is Bern.—The finances of Switzerland are in a very favorable condition. In 1873 the entire revenue, the greater part of it derived from duties and the postal system, was $7,152,704, and the expenditures were $7,154,712. Since 1848 duties are levied only on the frontiers of the republic, and not, as before, on the limits of each canton. A portion of the customs dues, as well as a great portion of the postal revenue, are paid over to the cantonal governments, in compensation for the loss of such former sources of income. In extraordinary cases, the federal government may levy a rate upon the various cantons after a scale settled for 20 years. The public debt at the close of 1873 amounted to $5,650,000, and the federal property to $5,691,000. The aggregate income of all the cantons in 1868 amounted to $8,320,000, the aggregate expenditures to $8,630,000. Schaffhausen and Appenzell Inner Rhodes had no public debt; many other cantons formerly without debt have of late contracted one for the purpose of building railways. In the majority of cantons the public property exceeds the debt. In 1868 the aggregate property belonging to the cantonal governments amounted to $54,770,000, and the aggregate debts to only $33,660,000.—The military establishment of Switzerland is based upon purely democratic principles. The fundamental laws of the republic forbid the maintenance of a standing army within the limits of the confederation. Every able-bodied citizen is actually a defender of the republic. The federal army consists of citizens from 20 to 44 years of age, and is divided into three classes according to age. The first class, comprising men from 20 to 34 years of age, constitutes the active field army; the second class, 34 to 40 years, the reserve army; and the third class, 40 to 44 years, the sedentary militia. The constitution of 1874 considerably extends the federal control in military matters. Both the army and the war material are at the disposal of the confederation, which in cases of emergency has the exclusive right to dispose of the men who do not belong to the federal army. All the laws relative to the army are enacted by the confederation, which also provides for the education of the troops. The Thun military academy furnishes the army with the highest class of officers and with instructors for the lower grades. There are special schools for different

branches of the service, especially for the artillery and riflemen. All the different classes are required to devote a certain number of days in each year to battalion and brigade drills and field manœuvres. The Swiss are accurate marksmen with the rifle, and meet constantly to practise and engage in trials of skill. There are clubs and societies in almost every valley and parish, and frequent matches; besides which a federal rifle match is held every year. The number of riflemen in the army list of 1874 was 13,918. Annual contests in wrestling also are held in many parts of Switzerland. In September, 1874, the field army numbered 84,369 men, the reserve army 50,069, and the militia 65,981; making, with administrative troops and the sanitary corps, a total of 201,257.—The first inhabitants of Switzerland are supposed to have been of Celtic origin, and to have immigrated from the northeast. Their collective name was Helvetians. (See Helvetii.) The high valleys near the sources of the Rhine, in the present canton of Grisons, were occupied by a tribe akin to the Tyrrhenians or Etruscans, called the Rhætians. In 113 B. C. two tribes of Helvetians, the Tigurini and Tugeni (from which are derived the names of Zürich and Zug), joined the Cimbri and Teutons in their inroads into Italy. In this war the Helvetian Divico, in 107, completely routed the Romans under their consul L. Cassius Longinus. After the defeat of the Cimbri in 101, the Helvetians returned unmolested to their mountains, followed, it is believed, by the scattered remnants of the Cimbri, to whom the foundation of the town of Schwytz is ascribed. In the time of Cæsar an entire tribe of the Helvetians, instigated by their leader Orgetorix, determined to conquer seats in Gaul, destroyed their towns and villages, and under the command of Divico crossed the Saône; but they were conquered by Cæsar at Bibracte (Autun), and driven back to their country. Soon afterward the Helvetian tribes were gradually subdued by the Romans, and even the Rhætians, who were the last to maintain their freedom, were compelled at length to yield. For several centuries Switzerland remained a province of the Romans, who introduced their manners, laws, and civilization, and founded several towns, as Augusta Rauracorum (Augst, near Basel), Curia Rhætorum (Coire), Vindonissa (Windisch, in Aargau), Aventicum (Avenches, in Vaud), and Eburodunum (Yverdun). In the 2d, 3d, and 4th centuries the country was often harassed by the invasion of German tribes, especially the Alemanni; the Celtic and Roman elements of the population mostly perished, the towns were sacked, and the country laid waste. In the 5th century the Burgundians, Alemanni, and Goths divided the country among themselves; but their dominion was short, and in the 6th century they were all brought into subjection by the Franks. Christianity, which had already begun to take root in Burgundian Switzerland, became under the rule of the Franks the religion of the entire country. Many bishoprics and convents were founded, and the bishops and many abbots obtained great political influence. Though wholly incorporated with the empire of the Franks, the country was in point of administration divided into two parts: the one, extending from the lake of Constance and the Rhine to the Aar and St. Gothard, was called Rhætia and Thurigau; and the other, comprising the present cantons of Geneva, Valais, Neufchâtel, Bern, Fribourg, Solothurn, &c., was called Little Burgundia. Under the weak reign of Charles the Fat (died 888), Switzerland, like many other parts of the empire, was lost to the Franks. The N. part came into the possession of the duke of Alemannia (Swabia), and thus became part of the German empire, while the S. part belonged to Burgundy. During the invasion of Germany by the Hungarians in the 10th century, many towns, as St. Gall, Basel, Zürich, and Lucerne, were fortified, and rose in importance. During the reign of the emperors of the house of Saxony the country was mostly held as fiefs by the vassals of the empire, in particular by the bishops and abbots, the counts of Kyburg (Zürich), Hapsburg and Lenzburg (Aargau), and Rapperswyl and Toggenburg (St. Gall); later also by the count of Savoy and the duke of Zähringen. Many of these noble families became extinct during the crusades; and the power and prosperity of the towns rose still higher, Bern and Fribourg even becoming free cities of the German empire. Zürich, Bern, and Basel formed an alliance, and tried to make themselves independent. Yet the independence of Switzerland did not proceed from them, but from the three ancient cantons of Schwytz, Uri, and Unterwalden, the inhabitants of which are believed to have descended from immigrants from Sweden, and which had never been conquered. They were only under the protection of the German emperor, near whom their rights were guarded by a *vogt*, first a count of Lenzburg, and afterward a count of Hapsburg. The elevation of Rudolph of Hapsburg to the imperial throne of Germany in 1273, and his conquest of Austria and other possessions of Ottocar of Bohemia, greatly increased the influence of the house of Hapsburg in Switzerland. Albert, the son of Rudolph, sought to incorporate the Swiss with Austria. Bern and Zürich at once resisted successfully; but in Schwytz, Uri, and Unterwalden he succeeded for a time. The convention entered into by 33 distinguished men of the three cantons on the Grütli or Rütli, a meadow on their common frontier, during the night of Nov. 7–8, 1307, led, on Jan. 1, 1308, to the expulsion of the Austrian officers and the destruction of their castles. The legend of Tell belongs to this period. The relation of the three cantons to the German empire remained at

first unchanged; but the war of Austria for reëstablishing its rule in the emancipated cantons, which lasted with many interruptions for about 200 years, ended with severing also the ties which bound Switzerland to Germany. The Hapsburgs also lost their possessions lying between the Alps and the Rhine, and their old family castles of Hapsburg and Kyburg. The league of the three old cantons, which had first been formed in 1291 and renewed in 1308, was again established as a perpetual confederacy in 1315, after the great victory over the Austrians at Morgarten on the confines of Schwytz and Zug. In 1332 Lucerne joined the confederacy, which received the name of the Four Forest Cantons (*Vierwaldstätte*). Zürich came in in 1351, Glarus and Zug in 1352, and Bern in 1353, when the eight united cantons erected the "perpetual league of the eight old places of the confederacy," so called because no new members were added to the confederacy till 1481, and these eight enjoyed many privileges till 1798. Other victories over Austria were gained at Sempach (Lucerne), July 9, 1386, and at Näfels (Glarus), April 9, 1388; after which the Swiss became aggressive, and at length, notwithstanding their defeats at Arbedo (Ticino) in 1422 and at St. Jacob (Basel) in 1444, annexed a considerable portion of Austrian territory. These protracted conflicts awakened such a fondness for warfare that many Swiss soldiers entered foreign armies, where until a very recent period they earned the questionable reputation of being the most loyal defenders of the cause which they espoused, even if it were that of despotism. Foreign enlistment without permission was forbidden by the federal government in 1860. There were occasional internal dissensions, and Zürich from 1440 to 1450 seceded from the confederacy. As at this time Schwytz had a predominant influence in the councils of the confederacy, its cantonal colors (white and red) were adopted as the confederate ensign, and the party name Swiss (Schwytz) became the designation of the entire people. In 1475 the cantons joined France, Austria, and some of the Alsatian free towns in the league against Burgundy. The Swiss gained a great victory over Charles, duke of Burgundy, at Granson, in March, 1476; the confederates annihilated his army at Morat in June; and the war terminated with the defeat and death of the duke at Nancy in January, 1477. (See Charles the Bold.) The admission of Solothurn and Fribourg into the confederacy in 1481 threatened a civil war, which was averted by the exhortations of the hermit Nicholas von der Flue. Other internal dissensions were terminated by a war against the German emperor (1498), which was concluded by the peace of Basel in 1499, and Basel and Schaffhausen, for faithful assistance, were admitted as members of the confederacy, to which Appenzell was added in 1513. The number of cantons thus rose to 13, and remained so till 1798. The Swiss conquered Lombardy for Duke Maximilian Sforza in 1512, and routed the French at Novara in 1513, but in 1515 lost the great battle at Marignano. They found France willing to conclude with them an advantageous peace in 1516, which was kept till 1798. The reformation of the 16th century led to open war between the Reformed and Catholic cantons, but soon after the battle at Cappel (Zürich) in 1531 peace was concluded, and every canton left at liberty to introduce or to oppose the reformation. (See Reformation, vol. xiv., pp. 246-'7.) Geneva freed itself, with the aid of Bern, from Savoy, and in 1536 became a Protestant republic, but without being admitted into the confederacy. Vaud was conquered by Bern from Savoy in 1536 and reformed; but on the other hand, the Catholic cantons of Lucerne, Uri, Schwytz, Unterwalden, Solothurn, and Fribourg formed in 1586, by the advice of Archbishop Charles Borromeo of Milan, the "golden league" for the common defence of the Catholic religion. The religious split long continued a prolific source of dissension between the cantons. In 1597 the canton of Appenzell, in order to prevent a religious war, was separated into two independent half cantons, the Catholic part being called Inner Rhodes, and the Reformed Outer Rhodes. In 1602 the Reformed were expelled from Valais, and in 1620 Protestantism was forcibly suppressed in the Valtellina. In Grisons a bloody civil war was kindled, in which other cantons also took part, and which made the country one of the chief seats of the war between France, Spain, and Austria. As the federal courts of Germany still made claims on Switzerland as belonging to the German empire, the Swiss sent the burgomaster Weltstein of Basel as their representative to the peace congress of Münster, which at the peace of Westphalia (1648) pronounced Switzerland entirely independent of Germany. From this time until the outbreak of the French revolution in 1789, the history of Switzerland presents few events of general importance. It had no foreign war, and the occasional religious contests at home were generally of short duration. The most important of them was the second war of Toggenburg in 1712, when 150,000 Swiss were in arms against each other. Other internal commotions arose out of the oligarchic form of government which was gradually established in the cantons of Bern, Fribourg, Solothurn, and Lucerne, and out of the oppressed condition of the subjected territories whose inhabitants were excluded from all political rights. In 1798 two French armies marched, without any respectable pretext, into Swiss territory, captured on March 5 the city of Bern, plundered its armory and treasury, and on April 12 proclaimed at Aarau the one and indivisible Helvetic republic, divided into 18 cantons, with Aarau as the federal capital. By the new constitution Bern was divided into four

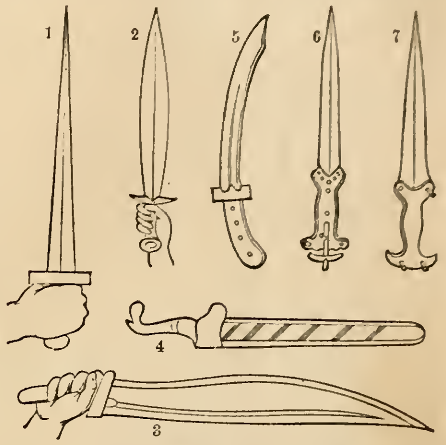
cantons, the subjected districts of Baden, Thurgau, Lugano, and Bellinzona were erected into cantons, Zug, Uri, Schwytz, and Unterwalden united into the one canton of the Forest Towns, and Appenzell, St. Gall, and the valley of the Rhine formed into the canton of Sentis. Geneva, Bienne (Bern), and several other portions of Swiss territory were incorporated with the French republic. The resistance of the old forest cantons proved useless, and the new constitution was gradually introduced. Overthrown on the entrance and advance of the allied armies under the command of Suvaroff, it was reëstablished after the victories of the French under Masséna. The withdrawal of the French troops in 1802 led at once to revolutions in almost every canton, and a general diet, consisting of an equal number of deputies from the formerly governing and the governed districts, was convoked at Schwytz; but again France interfered, 12,000 French troops subdued the old cantons, and deputies from all the cantons were ordered by Bonaparte to assemble at Paris for the purpose of reorganizing Switzerland. On Feb. 19, 1803, Bonaparte transmitted to them the act of mediation, by which the former cantonal system was restored, although the relation of subjected territories remained abolished. To the 13 old cantons 6 new ones were added, viz.: St. Gall and Grisons, which had formerly been allied with the confederacy without being members, and Aargau, Thurgau, Ticino, and Vaud, which had been subjected territories. At the head of the confederacy was again placed a diet (Ger. *Tagsatzung*), consisting of commissioners, voting according to instructions. It was to assemble in turn in the cities of Bern, Zürich, Lucerne, Basel, Fribourg, and Solothurn, and the burgomaster of the temporary capital (Ger. *Vorort*), under the name of *Landamman* of Switzerland, was to preside at the diet and to attend to all the current affairs of the year. In the democratic cantons the sovereign popular assemblies were reëstablished; in the others grand and little councils, the former being elected by a direct vote of the people, and the latter by the grand council. This new constitution was on the whole well received, and under it Switzerland for ten years enjoyed peace at home and abroad. After the battle of Leipsic the troops of the allied powers marched through Switzerland. Bern and others of the aristocratic cantons severed their connection with the Helvetic government instituted by the act of mediation, and civil broils ensued in a number of cantons. Yet the attempt to restore the former order of things had soon to be given up, and a new constitution, adopted by the federal diet on May 27, 1815, and sworn to at Zürich on Aug. 7, acknowledged all the 19 cantons constituted by the act of mediation, and added three new ones, Geneva, Valais, and the Prussian principality of Neufchâtel. This constitution was ratified by the great powers of Europe, which also declared the perpetual neutrality and inviolability of the confederation (Nov. 20). The territory of Switzerland was enlarged by portions of land ceded by France (the Dappes valley), Savoy (Carouge and several villages on the lake of Geneva and on the Rhône), and Austria (Rhäzüns, the Frickthal, Laufenburg, and Rheinfelden). The cantons of Solothurn, Grisons, Schwytz, and Appenzell Inner Rhodes adopted the constitution only with reluctance, and Nidwalden (one half of Unterwalden) had to be coerced into submission by force of arms. According to the new confederation the cantons guaranteed to each other their constitution, and united for the common defence of their independence. The diet was to assemble annually on June 1, alternately at Bern, Lucerne, and Zürich, and to it was reserved the right of declaring war, concluding peace, and forming alliances with foreign powers. The cantons retained the right of forming with foreign states special military agreements. The existence of the convents and cathedral chapters was guaranteed by a special article. The administration of federal affairs, during the time that the diet was not in session, was left to the temporary capital. In 1817 Switzerland, on the invitation of Alexander of Russia, joined the holy alliance, and from 1823 to 1828 it conceded to the urgent requests of the great powers of Europe a restriction of the liberty of the press and of the right of asylum. The aristocracy recovered in most cantons part of their former prerogatives, and several capital towns greatly enlarged their influence at the expense of the country people. The French revolution of July, 1830, led to violent political agitations in Switzerland. In several cantons the country people rose against the capital towns, and forced them to reorganize the cantonal constitutions on a more liberal and democratic basis. In the canton of Basel a permanent division into two independent half cantons, Basel City and Basel Country, was effected in 1832. In November some of the most conservative cantons, Uri, Schwytz, Unterwalden, Neufchâtel, and Basel City, formed the "league of Sarnen," and threatened to send no more commissioners to the federal diet if the commissioner from Basel Country were admitted. The federal diet interfered; the separate league was declared dissolved, and the refractory cantons had to submit to the federal authority. Altogether, liberal cantonal reforms were introduced in about two thirds of Switzerland. Encouraged by success, the progressive party conceived also the plan of revising the federal constitution, with the view of effecting a closer political union. The diet, on July 17, 1832, pronounced in favor of the revision; yet, when the amendments adopted by the diet were subjected to a direct popular vote, they were voted down by a coalition of the Catholic and radical parties. The large number of political refu-

gees, who gathered in Switzerland in consequence of the revolutionary movements of 1830, involved the country in serious difficulties with the great powers, which complained of the liberty granted to them by the federal diet. The latter endeavored to conciliate the powers by several resolutions restricting the liberty of the refugees (in 1834 and 1838), and even by the expulsion of some of the leading men among them (1836); yet the diplomatic collisions continued. The demand of the French government in 1838 for the expulsion of Louis Napoleon, who had been since 1832 a citizen of the canton of Thurgau, was declined by Switzerland, and almost led to a war, which was only avoided by his voluntary departure. An occasion for new religious contests was given by the conference at Baden in 1834, at which delegates of Bern, Basel Country, Aargau, Thurgau, Lucerne, Solothurn, and St. Gall undertook to regulate the relations of the Roman Catholic church in a manner which was rejected by the pope and the bishop of Basel as contrary to the rights and the spirit of the church. The articles of the conference provoked several insurrections, especially in the canton of Aargau, the government of which, to punish the revolted Catholic districts, decreed in 1841 the abolition of all the convents. Against this measure most of the Catholic cantons and the ambassador of Austria protested, as a direct violation of that article of the constitution of 1815 which guaranteed the continuance of convents and chapters. Upon the representations of the federal diet Aargau restored four female convents, a concession which did not satisfy Austria and the Catholic cantons; but the federal diet by 12½ votes dismissed the subject from its docket (Aug. 31, 1843). A cause of still greater trouble was a motion, made by Aargau at the diet of 1844, for the expulsion of the Jesuits from Switzerland. It was laid on the table by the diet; but when the Catholic *Vorort* Lucerne resolved (Oct. 24, 1844) to call the Jesuits to a cantonal institution, a great excitement spread throughout Switzerland. Two volunteer expeditions (December, 1844, and March, 1845) were undertaken for the purpose of overthrowing the government of Lucerne, but both were unsuccessful. On the other hand, the governments of Vaud, Bern, and Zürich, which had voted against the expulsion, had to give way to others which were in favor of the project. As thus the danger threatening the existence of the schools of the Jesuits increased, the cantons which either had called Jesuits to cantonal institutions, or which patronized them (viz., Lucerne, Uri, Schwytz, Unterwalden, Zug, Fribourg, and Valais), strengthened a separate alliance (*Sonderbund*) which had already been formed in 1843, and appointed a council of war for the emergency of a civil contest. A motion of Zürich at the diet of 1845 to declare the Sonderbund dissolved received only 10½ votes, but a change of government of Geneva and St. Gall secured for the motion a majority of 12½ votes on July 20, 1847. One Protestant canton (Neufchâtel), one Protestant half canton (Basel City), and one Catholic half canton (Appenzell Inner Rhodes) voted with the cantons of the Sonderbund. In September another resolution declared the expulsion of the Jesuits from all Switzerland. The diet collected an army of nearly 100,000 men under the command of Gen. Dufour, and on Nov. 4 resolved to execute the decree of July 20 by force of arms. The Sonderbund had raised a force of 36,000, which was to be supported by a *Landsturm* of 47,000 men. The isolated Fribourg was first attacked, and surrendered after an insignificant skirmish. On Nov. 23 the army of the Sonderbund was routed at Gislikon, near the frontier of the canton of Lucerne, the council of war, the government of Lucerne, and the Jesuits fled, and all the seven cantons submitted. In this war Lucerne was the head and centre of the seven Catholic cantons. Austria, France, and Prussia had openly declared during the war their sympathy with the Sonderbund, and in 1848 issued a joint note to Switzerland, demanding that the cantons of the Sonderbund be evacuated, and no change be made in the constitution of 1815, except by the consent of all the cantons. But the revolutions of 1848 drew off the attention of the great powers from Switzerland, and gave the latter an opportunity to hasten a thorough reformation of the federal constitution. The committee of revision began its labors on Feb. 17, 1848, and on June 27 the draft of the constitution was submitted to a direct vote of the people. A majority of the cantons and a large majority of the total population voting in favor of it, it was promulgated Sept. 12. In the same year the canton of Neufchâtel declared itself independent of Prussia, which entered against this act an inefficient protest. On Sept. 2, 1855, the royalists of Neufchâtel made an attempt to overthrow the government of the canton and to reëstablish the sovereignty of the king of Prussia. The movement was at once suppressed (Sept. 3), but led to serious complications with Prussia, which demanded the unconditional pardon of the captured royalists. The demand was supported more or less by all the great powers of Europe; and when the federal council refused to accede to it, Prussia broke off diplomatic relations, and made some warlike demonstrations. When, however, France and England promised their intercession with Prussia in behalf of a recognition of the independence of Neufchâtel, in case Switzerland would release the royalist prisoners, their advice was followed by the federal council. Prussia in 1857, at a conference of the great powers in Paris, resigned for ever its claims to Neufchâtel. In 1860 Switzerland protested against the annexation of Savoy to France, as a violation of the treaties of 1564 and 1816, by which the neutrality

of the districts of Chablais and Faucigny had been guaranteed. It demanded from France the cession of these two districts, but as it received little aid from the great powers, its representations were of no effect. The boundary question between Switzerland and Italy, submitted to the arbitration of George P. Marsh, United States minister to Italy, was decided on Sept. 23, 1874, in favor of Italy, definitely fixing the Swiss frontier at the point called the Cravaviola Alps, and was promulgated as obligatory on the two countries, June 11, 1875. In 1875 Switzerland and Italy concluded a new commercial treaty for ten years. —The principal works on the history of Switzerland are: *Geschichte der schweizerischen Eidgenossenschaft*, by Johannes von Müller and others (7 vols., 1780–1829), to the end of the 16th century, continued in a French translation by Monnard and Vulliemin to the 19th century (19 vols., Paris, 1837–'51); Heinrich Zschokke's *Geschichte des Schweizerlandes* (Zürich, 1822; English translation by Francis George Shaw, embracing Emil Zschokke's continuation to 1848, New York, 1855; new ed., 1875); Bluntschli's *Geschichte des schweizerischen Bundesrechts* (2 vols., Zürich, 1846–'52); and A. Morin's *Précis de l'histoire politique de Suisse* (5 vols., Geneva, 1855–'75).

**SWITZERLAND**, a S. E. county of Indiana, bordering on Kentucky, from which it is separated by the Ohio river; area, 220 sq. m.; pop. in 1870, 12,134. The surface is undulating and the soil fertile. The chief productions in 1870 were 132,865 bushels of wheat, 15,020 of rye, 309,183 of Indian corn, 27,970 of oats, 126,116 of potatoes, 19,446 tons of hay, 20,964 lbs. of wool, 174,821 of butter, and 17,342 gallons of sorghum molasses. There were 3,526 horses, 2,626 milch cows, 3,225 other cattle, 8,473 sheep, and 9,407 swine; 7 manufactories of carriages and wagons, 7 of cooperage, 1 of woollen goods, 6 flour mills, and 8 saw mills. Capital, Vevay.

**SWORD**, a weapon used in hand encounters, commonly made like a large knife, and sometimes pointed like a dagger. The ancient Egyptians possessed the art of imparting to bronze extraordinary hardness and elasticity, and employed this material for swords and daggers. Wilkinson describes the former as straight and short, from 2½ to 3 ft. in length, having generally a double edge and tapering to a sharp point. The Greeks had several varieties of swords of bronze, and at a later period of iron; and as seen upon coins, vases, &c., they appear to have been short cut-and-thrust blades, leaf-shaped or tapering from hilt to point, and provided with a scabbard, which was attached on the left side to a belt suspended from the shoulder or round the waist. The Lacedæmonian sword was curved on the sharp side, while the back was blunt, and the end was pointed obliquely toward the back. The Romans first used the Gallic sword, which had no point and was sharp on one side only; but after the battle of Cannæ they adopted the Spanish sword, which was short and straight, made for cutting and thrusting. The Gallic sword was worn on the left side, the Spanish always on the right. The swords used by barbarian soldiers and by gladiators were curved.

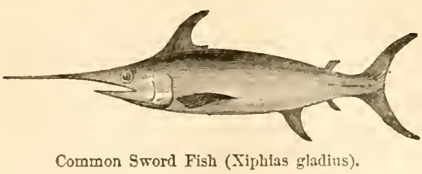


1. Greek Sword, from a Monument. 2. Greek Sword in the Royal Antiquarium, Berlin. 3. Lacedæmonian Sword, from a Vase. 4. Greek Sword in Scabbard, from a Vase. 5. Barbarian Sword, from the Column of Antoninus. 6 and 7. Roman Swords, in the Museo Nazionale, Naples.

The most famous swords were the Damascus blades of the middle ages, made probably of East Indian wootz, on the shores of the Mediterranean. (See DAMASCUS BLADES.) Next to these the swords of Toledo in Spain attained celebrity. Milan also was famous for its excellent swords during the middle ages. A manuscript psalter of the time of King Stephen gives a representation of two men grinding a sword blade, and there is no doubt of the early manufacture of swords in England. In the 17th century those made by the Germans were in good repute, and about the year 1689 unsuccessful efforts were made to establish the manufacture in Cumberland, England. In 1786 Mr. Gill of Birmingham, competing with German and English makers for supplying the East India company, produced a large number which bore the required test of bending till the length of the blade was reduced from 36 to 29½ in. Swords are still made at Toledo of as good quality as ever, but the manufacture employs only 70 or 80 hands. —The best of cast steel is required for good swords. The bars are hammered down by two men striking alternately; and if the blade is to have concave sides or other peculiarities of shape, these are obtained from the dies in which it is swaged. When shaped, it is hardened by heating in the fire to dull red and dipping point downward in a tub of cold water. It is tempered by drawing it through the fire until it acquires a blue color, and is then set or straightened by springing it with

the tongs in any required direction as it is held in a sort of fork standing in the anvil. After this it is ground upon a stone with a face adapted to that of the sword, flat or otherwise; is slightly heated to restore the temper impaired by grinding; and is finally polished with emery and crocus.—The small sword used in fencing is a slender weapon for the thrust only, and is the court dress sword. The broad sword, called sometimes the back sword, has but one edge.

**SWORD FISH,** the name of the *xiphiidæ*, a family of marine spiny-rayed fishes, allied to the mackerels, so called from the prolongation of the snout into a long, horizontally flattened, sword-like weapon. The sword consists of the vomer and intermaxillary bones, supported at the base by the frontals, nasal, and upper jaw. In form this fish resembles the mackerel; the scales are very small; the jaws proper, and sometimes the sword, are crowded with small, acute teeth, often hardly perceptible; the laminæ of each branchial arch are united into a band-like organ, with only superficial marks of separation, as in no other bony fishes; branchiostegal rays in the typical genus *xiphias* (Linn.) seven. The spinous dorsal begins near the head, high and sickle-shaped, extending nearly to the tail, and followed by a small soft fin; the anal is similar, but much shorter; ventrals wanting, or represented only by a pair of spinous rays on the throat; caudal deeply forked, on the sides having one or two large cutaneous folds; the pyloric appendages are collected into bundles and connected by areolar tissue, the branches forming two trunks inserted into the intestine close to the pylorus; the stomach cæcal and conical, and the air bladder large; the lower jaw in the young is proportionally longer than in the adult; the sclerotic forms a bony box, with a circular opening in the front for the cornea, rendering the eyes very movable. They are very swift swimmers, and feed on mackerel and other fishes collecting in shoals. The common sword fish (*X. gladius*, Linn.) attains a length of 12 to 20 ft., and is found in the Mediterranean and on both sides of the Atlantic; it uses its sword to destroy its enemies, and sometimes strikes at vessels, burying its weapon deep in their timbers. There are no ventral fins, and the sword is



Common Sword Fish (Xiphias gladius).

about three tenths as long as the body. It occurs on the North American coast from Nova Scotia to New York, being common in the summer in Vineyard sound and between No Man's Land and Block island; it is silvery white below, and tinged above with blackish blue, the sword dark brown above and lighter below. It is fond of pursuing the shoals of mackerel, and may be detected by the dorsal fin projecting above the water. They are taken by means of harpoons. The flesh is esteemed as food, both fresh and salted.

**SYBARIS,** an ancient Greek city of Lucania, in S. Italy, on the W. shore of the Tarentine gulf, between the rivers Crathis (now Crati) and Sybaris (Coscile), a short distance from the sea. It was founded by an Achæan colony about 720 B. C. The surrounding country was very fertile, and having large accessions from native Italian tribes, freely admitted to citizenship, the city rose rapidly to great wealth and power. When most prosperous, about 200 years after its foundation, Strabo says it was 50 stadia in circumference, ruled over 25 subject cities, and could muster an army of 300,000 men; while the knights in their religious processions numbered 5,000, or four times as many as the same class of citizens in Athens. Sybaris founded Posidonia, Laus, and Scidrus, and traded extensively. Its citizens were famed for effeminacy and love of luxury. Athenæus said no craft was permitted in the city which made a noise that might disturb the citizens; yet the arts conducive to pleasurable life were amply fostered. The aristocracy ruled till about 510 B. C., when Telys, a demagogue heading a democratic party, drove out the wealthier citizens and rulers, and raised himself to the position of tyrant. Of the exiled nobles 500 took refuge at Crotona, and Telys demanded their surrender. This was refused, and a war ensued in which a large army of Sybarites was beaten by one third the number of the Crotoniats, who sacked Sybaris, and turned the course of the river Crathis so that the city was inundated and buried in the deposits that the river brought down. Sybaris was never restored; its site is now a malarious marsh, and its exact position cannot be determined. Its surviving inhabitants, after remaining for many years at Laus and Scidrus, founded near it, with Athenian colonists, the city of Thurii.

**SYBEL, Heinrich von,** a German historian, born in Düsseldorf, Dec. 2, 1817. He studied in Berlin under Ranke, graduated in 1841 at Bonn, and was professor there in 1844–'5, then at Marburg till 1856, and subsequently at Munich, where he founded the first historical seminary established in Germany. He resumed his chair at Bonn in 1861, and in 1875 was appointed director of the archives at Berlin. In 1862–'6 he was a member of the Prussian chamber, and in 1867 of the constituent Reichstag of the North German confederation. His works include *Geschichte der Revolutionszeit* 1789–'95 (3 vols., Düsseldorf, 1853–'7; English translation by Perry, London, 1868; new ed., continued to 1800, 5 vols., Düsseldorf, 1874 *et seq.*); *Kleine historische Schriften* (2 vols., Munich, 1862–'9); *Die deutschen und auswärtigen Universitäten* (enlarged ed.,

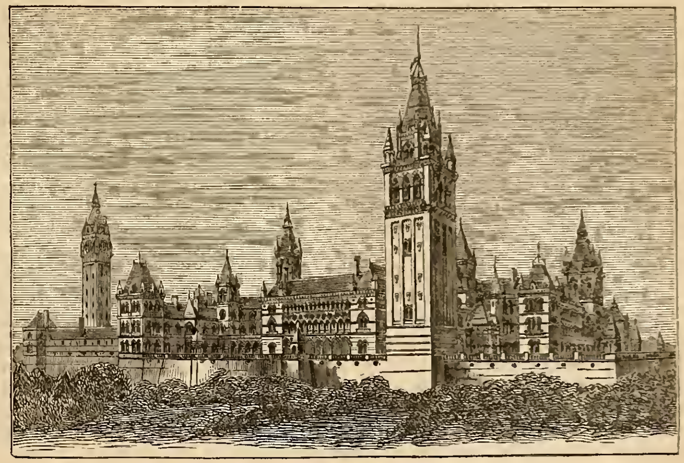
Bonn, 1874); and *Klerikale Politik im neunzehnten Jahrhundert*, in defence of Prince Bismarck's policy (1874; English translation by J. S. Henderson, London, 1874).

**SYCAMORE**, a name properly belonging to a species of fig (*ficus sycomorus*), the συκόμορος of the Greeks, and the plant so called in the Scriptures. The tree is common in Egypt; its light and durable wood was formerly used for mummy cases, and it is now planted as a shade tree and for its fruit. In the sacred dramas in the middle ages, the true sycamore not being at hand, the large maple was used to represent the tree into which Zacchæus climbed, and that in which the Virgin hid with the infant Jesus to avoid the fury of Herod. From this use the name sycamore was transferred to the maple (*acer pseudoplatanus*). (See MAPLE.) In the United States the plane or buttonwood tree is frequently called sycamore, as the leaves resemble in shape those of the sycamore maple.

**SYDENHAM, Floyer**, an English scholar, born in 1710, died April 1, 1787. He was educated at Oxford, where he took the degree of M. A. in 1734. He translated the greater part of Plato's works (3 vols. 4to, 1759–'80). Thomas Taylor completed the translation in 1804. Sydenham also published "A Dissertation on the Doctrine of Heraclitus" (1775), and *Onomasticon Theologicum* (1784). His sufferings from poverty in his old age, and his death in the debtors' prison, led to the foundation of the literary fund.

**SYDENHAM, Thomas**, an English physician, born at Winford Eagle, Dorsetshire, in 1624, died in London, Dec. 29, 1689. He graduated at Oxford, and in 1648 obtained a fellowship in All Souls' college, and studied there some years, visiting France in the mean while and attending the lectures of Barbeyrac. About 1660 he went to Westminster, and soon obtained a large practice and great reputation. Abandoning the routine system then in vogue, he based his practice on principles which recognize that there is in the human system a recuperative power, the *vis medicatrix naturæ*, and that this should be aided, not thwarted. He was the first who treated smallpox with cooling remedies, or intermittent fever with cinchona. The preparation known as Sydenham's laudanum was one of many valuable additions which he made to the materia medica. A collective edition of his works in Latin was published in London in 1785 (English translation, 1696).—In 1843 a society, composed mainly of members of the medical profession, was founded in London under the name of the Sydenham society, having for its object the republication of the works of Sydenham and of other eminent physicians of former times, otherwise inaccessible to professional readers in general, and published his works translated from the Latin by R. G. Latham (2 vols., London, 1848–'50).

**SYDNEY**, a city of Australia, capital of the colony of New South Wales, in Cumberland county, on the S. shore of Port Jackson, about 4 m. from its entrance, 450 m. N. E. of Melbourne; lat. 33° 51′ S., lon. 151° 14′ E.; pop. in 1871, 75,945, or including the suburbs, 134,758. Part of the town stands on a promontory, with Darling harbor on the W.; part occupies a narrow valley E. of this; and the remainder is on undulating ground extending S. and still further E., with extensive water frontage on the N. and N. E. The greatest length of the city is 3⅜ m. N. and S., and its breadth 2¼ m. E. and W. The total length of the streets is 115 m., and the number of houses 14,500. The main streets are laid out at right angles, but many are crooked and narrow, giving the city the appearance of an old English town. It is well supplied with water and lighted with gas. Public traffic is carried on by about 600 omnibuses and hackney coaches, and 30 steam ferry boats connect with the transmarine suburbs. Most of the public buildings, banks, and warehouses are of freestone in the Italian composite style. The exchange in the Corinthian, the government house in the Tudor, and the university in the perpendicular English style, are fine specimens of architecture. The new post office, opened in September, 1874, and the town hall, which is very large, are imposing edifices. Other noteworthy buildings are the new railway station, the courts of justice, the parlia-



Parliament Buildings, Sydney.

ment buildings, and the treasury. There are two cathedrals, Anglican and Roman Catholic, and about 120 other churches and chapels. There are three theatres, spacious markets, and several parks and gardens. Hyde park contains 40 acres, the Domain 138 acres, and the botanical gardens, the finest in the colonies, 38 acres. Prince Alfred park, Belmore park, and Moore park (500 acres) have all been recently laid out on the S. and S. E. sides of the city. Sydney is the residence of an Anglican bishop, who is the metropolitan of the Australian dioceses, and of a Roman Catholic archbishop. Connected with the university, whose degrees confer the same rank as those of the English universities, are St. Paul's Anglican college, St. John's Roman Catholic college, a Presbyterian college, and a Wesleyan college. There are also a normal school, a nautical school, many public and private schools, a free museum, a free public library, an observatory, three daily newspapers, and twelve weekly and eight monthly periodicals. Since 1855 a branch of the royal mint has been established here. The harbor is completely landlocked, and the largest vessels can come close to the wharves; and extensive ship yards and dry docks furnish every facility for repairing vessels. The port is well defended by several forts and batteries. The entrances at Port Jackson in 1872 were 1,022 vessels, tonnage 418,164; clearances, 854, tonnage 360,735. The exports to the United States for the year ending Sept. 30, 1874, amounted to $335,465. —Sydney was founded in 1788, and named in honor of Viscount Sydney, the colonial secretary of state. It was incorporated in 1842. In 1875 an intercolonial industrial exposition was held there.

**SYDNEY,** a port of entry and the capital of Cape Breton co., Nova Scotia, the chief town of the island of Cape Breton and its capital when a separate colony, situated in the E. part of the island, 195 m. N. E. of Halifax; lat. 46° 18′ N., lon. 60° 9′ W.; pop. in 1871, 2,900. The harbor is one of the finest in the world. In the vicinity are rich mines of bituminous coal, which are connected with the town by railway. There is considerable trade with Newfoundland and St. Pierre. Sydney contains an iron foundery, a tannery, a boot factory, ship yards, three branch banks, a court house, a masonic hall, a weekly newspaper, and churches of six denominations. The value of imports for the year ending June 30, 1874, was $70,554; exports, $588,935.

**SYDOW, Karl Leopold Adolf,** a German theologian, born in Berlin, Nov. 23, 1800. He studied under Schleiermacher, and was chaplain at Potsdam from 1837 to 1846, and for the last 30 years has been pastor of the *Neue Kirche* at Berlin. He was arraigned in 1872 for heresy, and was censured and fined, but retained his pastorate. Jointly with F. A. Schulze he has translated into German a collection of Channing's works (15 vols., Berlin, 1850–'53).

**SYLLA.** See SULLA.

**SYLLABUS** (Gr. σνλλαβός, a collection), the title given to a list of 80 propositions condemned at various times as erroneous by Pope Pius IX., which was sent by his order to the Roman Catholic hierarchy, Dec. 8, 1864. Several previous popes had condemned at one and the same time a series of propositions or heads of doctrine held to be heterodox or dangerous. Such were the 5 propositions containing the principal tenets of the Waldenses, condemned in 1318 by John XXII.; 21 from Huss, Wycliffe, and Jerome of Prague, condemned by Martin V. in 1418; 6 on the sacraments, from the writings of Peter de Osma, proscribed in 1481 by Sixtus IV.; 41 from the works of Luther and the early reformers, condemned in the bull *Exsurge, Domine*, by Leo X. in 1520; 76 from Baius, proscribed successively by Pius V., Gregory XIII., and Urban VIII.; 5 from the *Augustinus* of Jansenius, condemned by Innocent X. in 1653; 101 relating to Jansenism, condemned by Clement XI. in the bull *Unigenitus* in 1713; and 85 from the acts of the synod of Pistoja (1786–'7), condemned by Pius VI. in 1794. Pius IX. was moved to a similar act by a pastoral letter issued by Bishop Gerbet of Perpignan in July, 1860, censuring 85 propositions taken from various contemporary writers. On reading this document, the pope commissioned some Roman theologians to draw up a list, with references, of the errors which he had denounced during the 18 preceding years, in his consistorial allocutions or in his official letters. This list was annexed to the bull *Quanta cura*, issued Dec. 8, 1864, and communicated to the hierarchy by Cardinal Antonelli. In the bull, coming soon after the convention of Sept. 15 between France and Italy, the suppression of religious orders, and the confiscation of church property in Italy, the pope recalled the censure pronounced in the consistorial allocutions of Nov. 9, 1854, and June 9, 1862, against certain capital errors of the day, regarded as "the sources of all others" detrimental to civil society and to the church, and "opposed to the natural law written on the heart and in the very reason of man." He then formally condemned as erroneous various current doctrines, which inculcate that the perfection of civil government and social progress imperiously require that religion shall be ignored in the constitution and administration of states, or that no distinction shall be made between true and false religion; that the best government is that which represses or punishes acts committed against the Catholic religion only when these disturb the public peace, and that the most unlimited freedom of uttering one's opinions on every subject in public or in private, by writing or in print, shall be deemed an inherent right of every citizen in every form of government;

that the popular will, as expressed in public opinion or otherwise, is the supreme law, independent of all other, divine or human; and that in the political order accomplished facts, as such, have the force of right. Next came errors relating to the constitution and rights of the family, especially such as aim at refusing religious bodies all control over or share in education; the denial to the church as founded by Christ of all proper authority or jurisdictional rights, distinct from or independent of the state; the denial of power in the church to bind the conscience by any laws of hers, save only in so far as these are promulgated by the state; the denial of any validity to spiritual penalties decreed against secret societies in states which tolerate their existence, or of force in excommunications pronounced against persons usurping property belonging to the church, to religious orders, or ecclesiastical corporations, &c. This bull and the syllabus are to be taken as one authoritative act, the 80 errors designated in the latter being grouped under ten different heads, including pantheism and its adjuncts naturalism and absolute rationalism, moderate rationalism, and religious indifferentism; 20 propositions adverse to the constitution and rights of the church, 17 on civil society and its relations to the church, 10 on Christian marriage, 2 on the temporal princeship of the pope, and 4 on modern liberalism in its bearings on religion.—The appearance of both these documents created much excitement in France, where Jules Baroche, the minister of public worship, issued on Jan. 1, 1865, a circular letter to the French bishops forbidding the publication by them of the syllabus and of the doctrinal part of the bull. The liberal French press and the government journals also attacked these wide condemnations as "an act subversive of social order," "a monstrous error in politics as well as in the intellectual and moral order," "an attempt to restore an absolute theocracy, to set up a tyranny over everybody and everything." The minister declared the doctrine of the pope to be "contrary to the principles on which the empire reposed," and the *Journal des Débats* translated and analyzed the propositions condemned. Bishop Dupanloup replied to the latter, pointing out over 70 mistranslations and misconceptions; while nearly all the French prelates, including Archbishop Darboy, replied to the former, denouncing the ministerial prohibition. The bishop of Belley and the cardinal-archbishop of Besançon read both documents from the pulpit, and were prosecuted by the government. Elsewhere, though the proceeding of Pius IX. was generally condemned by the secular press, the civil governments did not feel called upon to interfere with the bishops, for whose special guidance the syllabus had been drawn up. In the beginning of 1871 Dr. Schulte, professor of canon and German law in the university of Prague, in a pamphlet entitled "The Power of the Roman Popes over Princes, Countries, Peoples, and Individuals," assumed that the syllabus with all its 80 propositions was an utterance *ex cathedra*, as defined by the council of the Vatican. This assumption, as well as the whole argument of Dr. Schulte, was assailed by Bishop Fessler of St. Pölten in Lower Austria, who had been secretary of the council, in his "True and False Infallibility of the Popes" (Vienna, 1871; English translation, London and New York, 1875), for which he received a congratulatory letter from Pius IX. In the autumn of 1874 the doctrines condemned in the syllabus were brought prominently before the public by Mr. Gladstone's pamphlet, "The Vatican Decrees in their Bearing on Civil Allegiance." From the syllabus and the bull *Quanta cura* he selected 18 propositions bearing principally on the liberty of the press, of conscience, worship, and speech, on the essential rights of both church and state, and their mutual subordination, on education, marriage, the abolition of the pope's temporal power, tolerance, and the reconciliation of the papacy with modern liberalism. The interpretation of the various propositions by Mr. Gladstone, and his conclusions therefrom, drew forth replies from Dr. Newman, Cardinal Manning, and other Roman Catholic writers, who accused him of mistranslating several propositions and misstating their sense. With regard to the doctrinal authority both of the bull *Quanta cura* and of the annexed syllabus, it is generally admitted by Roman Catholic theologians that the former has the character of an *ex cathedra* utterance, while the specific character of the latter is still a matter of dispute. All agree that the propositions condemned are erroneous, and that the condemnation should be accepted by all Catholics as final, while it is maintained by some that the syllabus has the same official and doctrinal value as the bull itself, and by others that the list of errors is only compiled for the convenience of bishops and theologians, each proposition bearing only that censure pronounced on it specially in the original document.

**SYLVESTER**, the name of two popes, besides an antipope. **I. Sylvester I., Saint**, born in Rome about 270, died there, Dec. 31, 335. He succeeded Pope Melchiades Jan. 31, 314, and concurred with the emperor Constantine in convening the council of Nice. (See NICE, COUNCILS OF.) He is frequently mentioned in history in connection with the "donation" said in the false decretals to have been made to him by Constantine of Rome and its temporalities. His feast is held on Dec. 31. **II. Sylvester II., Gerbert**, born at Aurillac in Auvergne about 920, died in Rome, May 12, 1003. He was a Benedictine monk of St. Gérold, Auvergne, studied under Hatto, archbishop of Vich in Catalonia, and at Rheims, and opened in that city a university course under the patronage of the emperor Otho II., which became famous throughout Europe. He constructed

terrestrial and celestial globes to illustrate his lessons, and a steam organ to explain his lessons on music; and he is said to have introduced the use of the Arabic figures in arithmetic, and to have invented the first wheel and weight clock. He was subsequently appointed abbot of Bobbio by Otho II.; but being unable to agree with the monks, he returned to Rheims after the death of Otho, resumed his teaching, and became secretary to Archbishop Adalberon of Rheims, and his successor through a contested election. He was deposed by Pope John XVI., and fled to the court of Otho III., who made him archbishop of Ravenna and had him elected pope, April 2, 999. He displayed uncommon zeal, talent, and severity in his administration. His universal knowledge caused him to pass for a magician. His letters, numbering 149, were published by Papire Masson (4to, Paris, 1621), and by André Duchesne in vol. ii. of his *Historiæ Francorum Scriptores.* His complete works are published in vol. cxxxix. of Migne's *Patrologie latine.*—See Bzovius, *Silvester II.* (4to, Rome, 1629); Hock, *Gerbert, oder Pabst Sylvester II. und sein Jahrhundert* (Vienna, 1837; French, Paris, 1842); and Milman, "Latin Christianity," vol. iii.

**SYLVIUS, Jacobus,** the Latinized name of a French anatomist, JACQUES DU BOIS, born at Louville, near Amiens, in 1478, died in Paris, Jan. 13, 1555. He graduated as A. B. in 1531, delivered lectures, and was appointed professor of medicine in the royal college of France in 1550. He is said to have originated the practice of injecting the blood vessels to facilitate their dissection. The oblique fissure separating the anterior and middle lobes of the cerebrum is called from him the fissure of Sylvius.

**SYMBOLS, Chemical,** abbreviations of the chemical names of the elements, which are combined into formulas, with or without quantitative signs, to represent the composition of compound bodies. The idea of representing the names of chemical substances by conventional signs or abbreviations appears to be a very old one. The alchemists were in possession of a set of hieroglyphics by which the metals and the four so-called elements, fire, air, earth, and water, and indeed many other substances, were designated. At a later period, as chemical knowledge became more consolidated, various modifications of the alchemistical notation were from time to time proposed, and adopted to a greater or less extent. Among these should be specially mentioned the system of notation offered in 1787 by Hassenfratz and Adet, as an appendix to Guyton de Morveau's revised system of nomenclature, since its failure enables us the better to appreciate the peculiar excellence of the system which now prevails. Here was a system of symbols by no means devoid of ingenuity, and much more complete than any previous method, published in connection with a new system of nomenclature, which was soon universally adopted, and recommended by the committee of the French academy by whom this nomenclature had been prepared; yet it met with little or no favor among chemists, and was soon forgotten. This last remark applies as well to the symbols proposed by Dalton in 1808, in connection with his writings upon the atomic theory. None of these systems ever came into general use, nor does it appear that they were of much value as instruments of study even in the special cases in which they were employed. It is to Berzelius that chemical science is chiefly indebted for the simple and rational system of notation now in use, which has done so much to advance knowledge and to lighten the labors of chemical investigators. This system, in its first outlines at least, appears not to have been the result of any premeditated plan or special study, but to have followed incidentally as a natural result from the investigation of the combining proportions of bodies with which its author was occupied. Thus in 1814 he first mentions his symbols in a foot note to a memoir upon nitrous acid (Gilbert's *Annalen der Physik*, xlvi., 154), as convenient abbreviations for expressing the composition of bodies, which he has himself frequently employed in his private memoranda. Subsequently a more complete exposition of the plan appeared in his *Lehrbuch*, and in Poggendorff's *Annalen*, 1826, viii., 7. As a sign to express the name and combining equivalent of an element, Berzelius chose the initial letter of its Latin name; and in those cases where the names of several elements commence with the same letter, he annexed to the common initial the first of the following letters in the Latin name of the element which is peculiar to it; thus, the symbol C indicates an equivalent of carbon, Cl an equivalent of chlorine, and Cr an equivalent of chromium. (For a complete list of these symbols, see EQUIVALENT, CHEMICAL.) There are various other symbols used in chemistry, some to express qualities as well as the atoms or molecules of substances, as, for instance, the signs which express the quantivalence of bodies. (See ATOMIC THEORY, vol. ii., p. 88.) The signs +, —, and = are also used in chemical writing for the purpose of joining the symbols of the elements together in formulas, as $K_2O + H_2SO_4 = K_2SO_4 + 2H$, or $C_6H_{12}O_6 - H_2O = C_6H_{10}O_5$. When united by the sign = the formulas are called equations. Thus the latter formula is an equation which represents starch as being formed from the elements of glucose or grape sugar, by the abstraction of a molecule of water or of the elements of such molecule. The quantity of any substance is usually expressed by placing a numeral before it, whether the substance is an element or a compound, unless where the numeral is used to express the number of separate elements or substances which enter into the composition of

a compound. Thus 3H signifies three atoms of hydrogen, and $3H_2O$ three molecules of water, one molecule of water being composed of two atoms of hydrogen and one of oxygen. The prefixed numeral however only includes those symbols which are not separated by a + sign or a comma, or which are included in parentheses; as $2KCl,PtCl_4$, which is the formula of potassic-platinic chloride, and which contains two molecules of chloride of potassium united to one molecule of tetrachloride of platinum. Two molecules of potassic-platinic chloride would be written $2(2KCl,PtCl_4)$. A numeral placed at the right of a symbol and a little below (or sometimes above) multiplies that symbol only. Thus, the formula of sulphuric acid, $H_2SO_4$, signifies that it contains two atoms of hydrogen, four of oxygen, and one of sulphur. A numeral placed in the same position with regard to any number of symbols placed in parentheses has the same function. Thus $(H_4N)_2CO_3$, which is the formula of normal ammonic carbonate, indicates that two molecules of the compound basyle ammonium, $H_4N$, are united to one molecule of the oxion $CO_3$, or carbion. A capital letter with a dash above it is often used to stand for a compound instead of an element, as $\bar{A}$ for acetic acid, $C_2H_4O_2$; $\bar{O}$ for oxalic acid, $C_2H_2O_4$. Other symbols and abbreviations are also given in the article ATOMIC THEORY.

**SYME, James,** a Scottish surgeon, born in Edinburgh in 1799, died there, June 26, 1870. He received his diploma as surgeon in 1821, and in 1823 became a fellow of the royal college of Edinburgh, and in 1843 of the English college of surgeons. From 1821 to 1833 he lectured on surgery, and in 1833 was appointed to the chair of clinical surgery at Edinburgh. He originated or aided in establishing many improvements, including the resection of diseased joints in place of amputation (a practice already introduced by Roux in 1812), the process for amputation of the foot at the ankle joint (known as "Syme's operation"), and the removal of large tumors of the lower jaw by exsection of the entire bone. His works include "The Excision of Diseased Joints" (1831), and "Principles of Surgery" (1832), both republished in Philadelphia (1866).—See "Memorial of the Life of James Syme," by Robert Paterson, M. D. (Edinburgh, 1871).

**SYMMACHUS, Cœlius,** a pope and saint, born at Sinagia in Sardinia about 440, died in Rome, July 19, 514. He was appointed archdeacon of the Roman church by Pope Felix III., and was elected to succeed Anastasius II., Nov. 22, 498. A strong minority of Eutychians, headed by the patrician Festus and favored by the Greek emperor Anastasius I., elected at the same time the archpriest Laurentius, who had consented to sign the *Henoticon* of the emperor Zeno. The claims of the two parties were referred to the arbitrament of Theodoric, king of Italy, who decided in favor of Symmachus, Laurentius being appointed bishop of Nocera. A council held in Rome in March, 499, having enacted decrees against all bribery and intrigue in papal elections, the opposition was renewed, and Laurentius secretly returned to Rome. Symmachus was accused of peculation and adultery, and Rome became the scene of rioting and bloodshed. A council of all the Italian bishops was convened at Rome in 502, and Theodoric hastened thither to secure tranquillity. The pope was unanimously acquitted of the charges brought against him. In France the bishops declined to acknowledge the competency of a local synod to sit in judgment on their superior, and a third council met in Rome in 503, to which the emperor Anastasius (whom Symmachus had excommunicated) sent representatives, who accused the pope of Manichæism and of promoting sedition. Symmachus, through his legate Ennodius, declared that he had freely submitted to the judgment of the former bishops, proved that he had combated Manichæism, and promised to restore the emperor to his communion as soon as the latter ceased to protect Eutychianism. With the council ended the schism in Rome, but Anastasius persecuted all who sustained Symmachus. The latter published a treatise in which he refuted the charges against his doctrine and morality. His feast is held on July 19.

**SYMMACHUS, Quintus Aurelius,** a Roman author of the 4th century A. D. He was educated in Gaul, and, after being quæstor and prætor, was appointed in A. D. 365 corrector of Lucania and the Bruttii. In 373 he was proconsul of Africa, in 384 prefect of Rome, and in 391 consul. He was a sincere pagan, and labored to maintain his faith. His extant works are 10 books of epistles containing 965 letters, and fragments of orations which Angelo Mai discovered in one of the palimpsests of the Ambrosian library, and others from a Turin and Vatican manuscript. The first edition of the epistles was published in the pontificate of Julius II. One of the best is that of Scioppius (4to, Mentz, 1608).

**SYMMES, John Cleves,** an American soldier, born in New Jersey about 1780, died at Hamilton, Butler co., Ohio, May 28, 1829. He entered the army as ensign in 1802, fought in the war of 1812, settled at Newport, Ky., and wrote and lectured on his theory that the earth is hollow, open at the poles, and capable of being inhabited within. He published "Theory of Concentric Spheres" (12mo, Cincinnati, 1826). For an abstract of Symmes's theory and arguments, see the "Atlantic Monthly" for April, 1873.

**SYMPATHETIC INK.** See INK, vol. ix., p. 284.

**SYMPHONY** (Gr. σύν, with, and φωνή, voice), a term originally signifying merely a concordance of tones, but applied successively to certain vocal compositions, to compositions partly vocal and partly instrumental, to short introductory or intermediate instrumental passages in compositions which are predominantly vocal, and finally to elaborate and extended com-

positions for instruments only and in the sonata form. In this sense the word is now generally used. The germ of the modern symphony may be found in the suites prefixed by Scarlatti to his operas, which he designated as the symphony, consisting of three movements: 1, allegro; 2, andante; 3, allegro. But it was not till the time of Haydn, called the father of the symphony, that this kind of composition took its present form. He added a fourth movement, the minuetto, and elaborated the whole structure of the symphony. He composed 118 works of this kind. The form that Haydn fixed upon was adopted by Mozart and Beethoven, the latter especially giving a breadth, dignity, and grandeur to his symphonies that have made them the masterpieces of this form of musical art. In the final movement of his ninth or choral symphony he introduced vocal music, an example which has not been followed by later composers. Mendelssohn, Gade, Reinecke, Liszt, and Raff are among the more modern composers of works of this class.

**SYMPLEGADES.** See Argonauts.

**SYNAGOGUE** (Gr. συναγωγή, assembly, place of assembly; Heb. *beth hakkeneseth*, house of assembly), a building appropriated to worship and the performance of public religious rites in Jewish congregations. Corresponding to the word church in Christian terminology, the term is also applied to the Jewish community in general. The earliest synagogues, established in the times of Persian and Greek rule in Judea, were also for deliberative purposes. (For the "great synagogue" or assembly see Hebrews, vol. viii., p. 591.) In subsequent centuries they were also used as seats of popular as well as higher instruction. In modern Jewish communities this is mostly imparted in a separate building, called *beth hammidrash*, house of study. The synagogue is generally a high building, facing the four cardinal points, and provided with seats and desks on the floor for the male members of the congregation, and with galleries for the females. The east wall, which all must face during the recital of certain prayers, encloses the "holy ark" (*aron hakkodesh*), in which Hebrew copies of the Pentateuch, written on vellum, are deposited; and opposite it, near the centre, is the platform (*bimah*) on which the reading from the same is performed by the reciter or cantor (*'hazan*), or by a special reader (*kore*). Sermons or lectures are delivered from a smaller platform adjoining the "holy ark," by the rabbi or a special preacher or lecturer. The offices of reciter, reader, and lecturer are often united in the same person. Of late the use of the choir has become frequent, and the internal arrangements of the synagogues have been more and more assimilated to those of Christian churches.

**SYNESIUS**, a philosopher of the 5th century, born in Cyrene, Africa, about 379, died at Ptolemais about 430. He was of an ancient Greek family, studied at Alexandria under Hypatia, and at Athens, and on his return to Cyrene devoted himself to literary pursuits. Famine having come upon Cyrene about 397, Synesius was sent to Constantinople to solicit aid, and was successful. After three years' stay in the Byzantine capital, he returned to Cyrene, and soon afterward, under the influence of a Christian wife, renounced paganism. In 410, on the death of the bishop of Ptolemais (now Tolmeta in Barca), Synesius was chosen to the see, although he had not been baptized, was married, and held opinions not regarded in the church as orthodox. He accepted the post with reluctance, was baptized, and after seven months of preparation entered upon his episcopal duties. He was a Neo-Platonist before he became a Christian, and during his episcopate explained Christian dogmas in the light of his philosophy, inclined to the preëxistence of the human soul, believed in its immortality, held the resurrection to be a myth, and conceived the Trinity as a triple-headed energy displaying the innate nature of the "unity of unities." His works consist of epistles, treatises, and hymns. The best complete collection of them is that of Petau, in Greek with a Latin translation, editions of which appeared at Paris in 1612, 1633, and 1640. A new and more critical edition was published by Krabinger (2 vols. 8vo, Berlin, 1851). Many editions of the hymns have been published with translations into various tongues. A French version first appeared in 1581, and new ones in 1836 and 1839. See also Migne's *Patrologie grecque*, vol. lxvi.; and Kolbe, *Der Bischof Synesius von Cyrene* (Berlin, 1870).

**SYPHAX**, a Numidian prince, born about 250 B. C., died in 201. In 213 he was king of the Massæsylians, the westernmost tribe of the Numidians, and was at war with Carthage, in which he was encouraged by the Romans. Carthage, however, induced Gala, king of the Massylians, to declare war against him, and Syphax was defeated by Hasdrubal and Gala's son Masinissa. Syphax fled to Mauritania and collected a new force, but was again defeated by Masinissa. He subsequently regained possession of his throne, and Hasdrubal, to prevent his yielding to the overtures of Scipio for an alliance, gave him his daughter Sophonisba in marriage. On the death of Gala, Syphax with Carthaginian aid wrested the throne from Masinissa, and made him a fugitive. When Scipio landed in Africa in 204, Syphax joined the Carthaginians with an army of 50,000 foot and 10,000 horse. He encamped in the vicinity of the Romans, and during the siege of Utica held prolonged negotiations with Scipio; but the latter suddenly fell upon his camp in the night, set fire to its straw huts, and nearly destroyed his army. Two more armies raised by him were defeated, and he was finally made a prisoner. Polybius says he appeared in Scipio's triumphal procession, but Livy denies it.

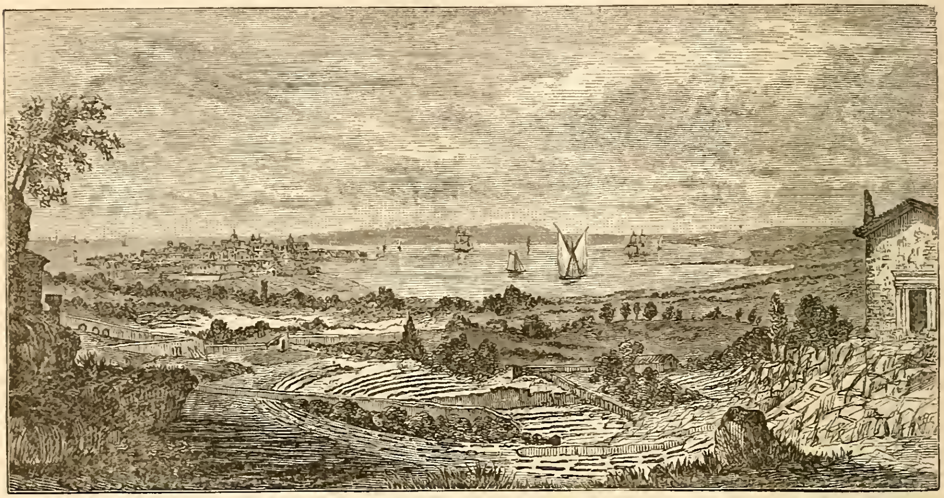
**SYPHILIS.** See Skin, Diseases of the, in Supplement, p. 883.

**SYPHON**, an inverted U-shaped tube used to draw liquids over the containing walls of reservoirs. It acts upon the principle that the flow will be in the direction of that leg which contains the greatest vertical height of liquid. The instrument will act only when the bend at the top is not higher above the level of the water in the reservoir than the atmospheric pressure at the locality is capable of sustaining a column of the liquid acted upon, which for water could only be a little over 33 ft. at the sea level, and at a height of 15,700 ft. less than 20 ft. (See PUMP, vol. xiv., p. 82.) If the liquid is mercury, the bend of the syphon could not be more than 29 or 30 in. above the level in the reservoir at the sea level. In practice the outer or discharge leg is usually longer than the one immersed in the liquid; but the only requirement is that its orifice shall be lower than the level of the liquid. It is convenient to have a suction pipe attached to the outer leg for producing exhaustion, the lower orifice in that leg being closed at the time.

**SYRA**, or **Syros. I.** A Grecian island, included in the Cyclades, 20 m. N. W. of Paros; area, 45 sq. m.; pop. in 1870, 26,480. It is of very irregular outline, with steep and rugged coasts. The chief productions are wheat, barley, cotton, figs, silk, and especially wine, whose praises have been sung by Homer. **II. Syra, New Syros**, or **Hermopolis**, the capital of the island and of the Greek nomarchy of the Cyclades, situated at the head of a bay on the E. coast, near the site of the ancient city; pop. in 1870, 20,996. It is the seat of a Roman Catholic bishop, and of the Greek bishop of the Cyclades. It is the principal commercial port of Greece and an important station for steamers. The imports in 1873 amounted to £791,500, and the exports to £172,337. The old part of the town, originally built on a hill as a protection against pirates, is inhabited chiefly by Roman Catholics, and the lower part by Greeks. At the close of the Cretan war in 1869, the port was blockaded by Hobart Pasha.

**SYRACUSE** (It. *Siracusa* or *Siragosa*). **I.** A province of Sicily, on the E. coast, bordering on Catania and Caltanisetta, and the Mediterranean; area, 1,429 sq. m.; pop. in 1872, 294,885. It is chiefly mountainous, but the south is a plain. The principal rivers are the Anapo, Abisso, and Ragusa. The valleys of these rivers, the bases of the mountains, and the districts along the coast are very fertile, and contain excellent pastures and some good timber. Agriculture and cattle raising are the chief occupations. The principal products are grain, barley, olives, wines, fruit, flax, and hemp. Among the mineral products are marble, agates, stalactites of various colors, and bitumen. The province is divided into the districts of Syracuse, Noto, and Modica. **II.** A city (anc. *Syracusæ*), capital of the province, on the E. coast, 30 m. S. S. E. of Catania, and 81 m. S. by W. of Messina; pop. in 1872, 22,179. It is fortified, and maintains a garrison, but is commanded by the heights of Achradina. It is the see of a bishop, and has a fine cathedral, partly on the site and partly composed of the ancient temple of Minerva, numerous palaces, and several churches and convents. The streets are narrow, and there are extensive ruins of amphitheatres, baths, &c. The city has some trade in wine, oil, brandy, fruits, salt, saltpetre, sulphur, and a little grain.—The ancient Syracusæ was the largest city of Sicily; its walls, flanked by towers, were about 22 m. in circuit, and the number of inhabitants in its most prosperous period is stated by different writers at 500,000, 900,000, and even 1,200,000. It really consisted of five towns adjoining each other, but separated by walls, viz., Ortygia, Achradina, Tyche, Neapolis, and the Epipolæ, and hence was sometimes called Pentapolis. The original city was Ortygia, on an oblong island about 2 m. in circuit, between the Great or Greek harbor on the west and the Little harbor on the east; after a time it was connected with the mainland by a causeway, and was then spoken of as Ortygia on the peninsula. Achradina, which was next in age, was on the other side of the Little harbor, and extended along the sea coast for about 3 m., E. of the port of Trogilus, without the limits of the city; it was built partly on the lowlands along the shore, and partly on the heights which rise in a wall of rocks some little distance inland. N. W. of Achradina and on the same range of heights stood Tyche, separated from it only by a double wall and a highway between; it extended northward about 2 m., and at its W. extremity were several heights named the Epipolæ, which were enclosed by Dionysius the Elder and formed one vast fortress. S. of Tyche, and opposite Ortygia, on the lowlands and extending to the wall of Achradina, at the foot of the heights, was Neapolis or the new town. W. and S. of Ortygia, around the marshy shores of the Great harbor as far as the rocky peninsula of Plemmyrium, were suburbs and gardens. After the Roman conquest, as the city declined in wealth and population, its limits became more restricted; at the time of Augustus it occupied only Ortygia and the lower part of Achradina, and since its capture by the Saracens it has been confined to the Ortygian peninsula. The heights of Achradina now present only a surface of rock, the ancient buildings and the soil having been alike removed. The sea has undermined the shore, the walls have disappeared, and over the elevated and extensive plain only steps hewn in the rock or a few courses of stone give evidence of the vast population which once inhabited it. On the peninsula and the lowland portion of Achradina and Neapolis, evidences of the former greatness of Syracuse are more abundant. Near the borders of Tyche, Achradina, and Neapolis is the ancient theatre hewn out of the rock and now much overgrown with bushes; it is 440

ft. in diameter, contained 60 ranges of seats, all cut in the rock, and could accommodate 24,000 spectators. Not far from this are the ruins of an amphitheatre of the Roman period. Nearer to Ortygia are the ruins of the palace of Agathocles, and on the peninsula are traces of several other palaces. The *lautumiæ* or *latomiæ*, originally quarries cut in the wall of rocks which formed the face of the heights of Achradina, and excavated to the depth of 60 to 80 ft., are still perfect. Some of them were used as prisons; in one the Athenian



Syracuse—Ruins of Theatre in the Foreground.

prisoners were confined on the surrender of Nicias, and most of them perished. Near the site of the ancient theatre, on one side of the quarry, is that remarkable prison cut in the rock, now called the "ear of Dionysius." There are also catacombs of great extent containing subterranean streets of tombs, in which Greek and Roman, Christian and Saracen, have all found burial. The remains of a great aqueduct begun by Gelon and improved by Hiero also exist. Near the left bank of the Anapo, outside the walls and S. W. of the city, are the ruins of the temple of Jupiter Olympius. The celebrated fountain of Arethusa, long in a ruinous condition and used by washerwomen, has been repaired and beautified by the city authorities; a wall separates it from the sea. There are also remains of several baths, one of them with a spiral staircase. In the museum of the modern city are preserved statues, vases, coins, and inscriptions gathered from the ruins.—Syracuse was founded by the Corinthians, under Archias, about 734 B. C. Within 70 years it began to send out colonies, among which were Acræ (664), Casmenæ (about 644), and Camarina (599). In 486 an oligarchy called the Geomori, or Gamori, who had usurped the government, were overthrown. They withdrew to Casmenæ, but Gelon, despot of Gela, restored them to power, reserving for himself the supreme government. (See Gelon.) Hiero, his successor (about 478), was a patron of literature and the arts. His brother Thrasybulus succeeded him in 467, but his tyranny soon caused his expulsion, and a popular government was instituted. (See Hiero.) In 415 the Athenians formed a league against Syracuse, and besieged it the following year. The Spartans came to the aid of the Syracusans, and in September, 413, a great naval battle was fought, in which the Athenians, under Nicias and Demosthenes, were defeated, their ships destroyed, about 30,000 men killed, and 10,000 made prisoners. In 405 Dionysius the Elder, taking advantage of the popular alarm at the aggressions of the Carthaginians, made himself despot of the city, concluded a peace with Carthage, and ruled vigorously but tyrannically for 38 years. He fortified the town, and in 397 commenced war against the Carthaginians, and defeated them. Twelve years later he had extended his dominion over the greater part of Sicily and a part of Magna Græcia. He was succeeded in 367 by his son Dionysius the Younger, whose tyranny and debauchery brought about his expulsion by Dion in 357; he regained his power in 346, but was finally expelled by Timoleon in 343. (See Dionysius.) The restoration of liberty to Syracuse by the latter was followed by unexampled though brief prosperity; and 26 years later Agathocles acquired despotic power over the city, and used it for 28 years to plunge her in new and destructive wars. (See Agathocles.) After his death (289) a short respite was had, but soon new tyrants assumed the sway, till in 270 Hiero II. obtained supreme power, and maintained a firm

and judicious administration for 54 years. In 263 he made a treaty with Rome, whose steadfast ally he thenceforward became. During his reign Syracuse attained to its highest splendor. With his death (216) a great change took place. His grandson and successor Hieronymus abandoned the alliance of Rome for that of Carthage, and after his death the Carthaginians brought about an open rupture with Rome, which led to the siege of Syracuse by Marcellus (214–212), a siege rendered illustrious by the patriotic efforts of Archimedes, but which finally resulted in the capture and plunder of the city. The magnificent works of art then carried as plunder to Rome gave the first impulse to the love of Greek art among the Romans. Syracuse fell into decay, and lost in wealth and population. Augustus in vain endeavored in 21 B. C. to restore it by sending a Roman colony. In the 4th century A. D., though much decayed, it was still one of the largest cities of Sicily. It fell into the hands of the Goths at the overthrow of the western empire, but was recaptured by Belisarius in 535, and remained a fief of the Byzantine emperors till 878, when, after a siege of nine months, it fell into the hands of the Saracens, who massacred its inhabitants, destroyed its fortifications, and burned the city. In 1088 Count Roger of Sicily made himself master of Syracuse. It was partially rebuilt and fortified by Charles V., but in 1542, 1693, and 1757 was nearly destroyed by earthquakes. On April 8, 1849, during the Sicilian insurrection, it surrendered to the Neapolitan fleet, and in 1860 it espoused the cause of Garibaldi.

**SYRACUSE,** a city and the county seat of Onondaga co., New York, at the head of Onondaga lake, on a creek of the same name, 147½ m. by the New York Central railroad W. by N. of Albany and 150½ m. E. of Buffalo; lat. 43° 3′ N., lon. 76° 9′ W.; pop. in 1850, 22,271; in 1860, 28,119; in 1870, 43,051, of whom 13,990 were foreigners, including 5,062 Germans and 5,172 Irish; in 1875, 49,808. The main portion lies in the valley of the creek, while the E. part is on two ridges, the summits being about 200 ft. above the lake. It is very regularly laid out; but few of the streets are less than 66 ft. wide, and many of them 99 ft., well shaded, with occasional small ornamented squares. The business portion is substantially built of brick; but the great majority of the dwellings are of wood, surrounded with lawns and gardens. The court house, of Onondaga dressed limestone, besides the usual court rooms, contains the library of the court of appeals (6,000 volumes); it cost $40,000. The city hall is of brick, on the N. side of a little park. The state armory, on Armory park (about two acres), is of brick, covers an area of 35,000 sq. ft., and cost $85,000. The Onondaga County savings bank is a fine building of Onondaga limestone in the renaissance style, costing $300,000. The Syracuse savings bank, in course of construction, is of Ohio buff sandstone with trimmings of New Jersey red sandstone. The first Presbyterian church, the costliest in the city, is of Fulton brown stone in the middle Gothic style, with a lofty spire. Syracuse university is on an elevation in the S. E. part of the city, with diversified grounds comprising 50 acres. The building is of rough dressed limestone ashlar, with fine cut trimmings in the Italian style, is 80 ft. by 180, and three stories above the basement. On a beautiful elevation just W. of the corporate limits of the city stands the New York state asylum for idiots, an elegant structure in the Italian style erected in 1855. (See IDIOCY, vol. ix., p. 174.) The principal cemetery is Oakwood, comprising about 150 acres, in a fine natural situation in the S. E. quarter of the city. It has been handsomely laid out, and contains many fine monuments.—Syracuse is an important railroad centre; 38 passenger and 60 freight trains arrive and depart daily. The diverging lines are as follows: the Oswego and Syracuse; Syracuse, Phœnix, and Oswego; Syracuse and Northern; New York Central; Syracuse and Chenango; Syracuse, Binghamton, and New York; and the Auburn branch of the New York Central. The Erie canal passes through the city, and the Oswego canal runs N. from near the centre. In 1874, 110,000 tons of freight, exclusive of wood and lumber, cleared at the collector's office. The controlling interest has always been the manufacture of salt. The springs were first visited by Jesuit missionaries in 1654, who made some salt and carried it to Quebec. From this time to the settlement of the whites in 1787 it was manufactured by the Indians and was an article of traffic. The manufacture has steadily increased since the settlement. In 1797 the state took control of the springs and passed laws for the regulation of the business. From 1797 to 1806 inclusive, 78,000 bushels were made; 1807 to 1816, 267,000; 1817 to 1826, 608,000; 1827 to 1836, 1,594,000; 1837 to 1846, 3,058,000; 1847 to 1856, 5,083,000. In 1874, 6,029,300 bushels were manufactured on the reservation, mostly in the city. There are 20 salt companies, which manufacture both by solar and artificial heat, employing a vast amount of capital and hundreds of men. There are about 90 other manufactories, producing articles in 1874 to the value of about $14,000,000. The most important are a blast furnace, Bessemer steel works, two rolling mills, three engine and boiler works, five founderies and machine shops, a bolt and nut factory, a manufactory of mower and reaper knives, a railroad journal-box factory, seven planing mills and sash, door, and blind factories, two fruit-canning establishments, an extension table factory, five manufactories of musical instruments (organs, pianos, &c.), one of picture frames, one of glass, two of matches, one of agricultural implements, one of mowers and reapers, three of saddlery hardware, three of boots and shoes, seven of ready-made clothing, many of cigars, two of

furniture, two of paper boxes, two of silver ware and jewelry, numerous barrel factories, seven breweries, three flouring mills, gas works, and six stone-dressing yards. There are five national banks, with an aggregate capital of $1,130,000; two state banks, capital $440,000; a trust and deposit company; two private banking houses, and three savings institutions, with upward of $7,000,000 deposits.—The city is divided into eight wards, and is governed by a mayor and a board of eight aldermen (one from each ward). It has an effective police force, a good fire department, water works, and street railroads. The assessed value of property is $12,310,937; funded debt of the city, $1,339,000. The principal charitable institutions are the county orphan asylum, St. Vincent de Paul's asylum for children, the "Home" for aged and indigent females, St. Joseph's hospital, and the house of the Good Shepherd. There are a high school and 15 other public schools, with graded departments and an average attendance of 6,434 pupils. The central library in the high school building, a free circulating library under the direction of the board of education, contains about 12,000 volumes.—Syracuse university was established by the Methodists in 1870, and opened in 1871. The plan is that of an assemblage of colleges of both undergraduate and professional grades, and three of these have been established, viz.: the college of the liberal arts, opened in 1871, which in 1875 had 11 professors and 148 students, and which confers degrees in the arts, philosophy, and science; the college of physicians and surgeons, established in 1872, which in 1875 had 15 professors and 60 students; and the college of the fine arts, established in 1873, which in 1875 had 8 professors and 22 students. The number of students in the several preparatory departments in 1875 was 142, making a total of 372 students. The library contains about 8,000 volumes. All the colleges are open to students of both sexes, who pursue the same courses of instruction in the same classes. While the responsibility of support and direction devolves mainly upon the Methodist Episcopal church, all sectarian differences are ignored, and attendance upon chapel exercises is not compulsory. In 1875 the assets of the university amounted to about $600,000, of which the city contributed $100,000, and the rest was derived from private subscriptions.—The Onondaga historical association, incorporated in 1863, has a library of 1,500 volumes and valuable cabinets. The young men's Christian association, organized in 1858, has an excellent library and reading room. There are three daily and eleven weekly newspapers, including two issued on Sundays. The number of churches is 41, viz.: 2 Baptist, 1 Church of Christ, 2 Congregational, 4 Episcopal, 1 Independent Christian, 3 Jewish, 5 Lutheran, 9 Methodist, 4 Presbyterian, 1 Reformed, 7 Roman Catholic, 1 Unitarian, and 1 Universalist.—The first settlement within the corporate limits was made by Ephraim Webster, an Indian trader, near the mouth of Onondaga creek, in 1787. In 1789 Asa Danforth settled in that part now known as the first ward, then called Salt point, and began the manufacture of salt. It soon took the name of Salina, and became the most important place in the county. The first settlement in the central portion of the city was made in 1797. It increased slowly, and assumed successively the names of Bogardus Corners, Milan, South Salina, Cossitt's Corners, Corinth, and Syracuse (in 1824). It was incorporated as a village in 1825. The Erie canal having been completed in that year, the rival villages of Salina and Syracuse rapidly increased in population, and in 1847 were consolidated in the city of Syracuse.

**SYRIA** (Turk. *Suristan;* Arab. *Esh-Sham*), a territory of Asiatic Turkey, bounded N. by Adana and Marash, E. by the Euphrates and the Syro-Arabian desert, S. by Arabia, and W. by the Mediterranean, between lat. 31° and 37° 20′ N., and lon. 34° and about 40° E.; area, about 60,000 sq. m.; pop. about 1,000,000. It includes parts of the vilayets of Syria (capital Damascus; area, inclusive of a part of the desert, 66,000 sq. m.; pop. in 1871, 518,750) and Aleppo, the latter including Marash and some districts E. of the Euphrates (area, 40,750 sq. m.; pop. 535,714). Besides the large gulf of Iskanderun (the ancient gulf of Issus), at the extreme north, which extends between Syria and Asia Minor, the coast is indented by several small bays, as those of Tripoli, Beyrout, Saida, and Acre. The principal rivers are the Jordan, the Asi or Aasy (the ancient Orontes), the Litany (Leontes), the Yarmuk (Hieromax), the Barada (supposed to be the Scriptural Abana), and the Awaj (Pharpar). The Euphrates drains the N. E. border. The only important lakes are the Dead sea and the lake of Tiberias or Gennesaret. The Taurus range forms a part of the N. boundary, and separates Syria from Asia Minor. The two parallel chains which extend through Syria from N. to S., the Libanus or Lebanon and the Anti-Libanus, are offsets of the S. W. continuation of that range known to the ancients as the Amanus (now Alma Dagh). The W. or Lebanon chain runs parallel to the coast, and seldom more than 12 m. distant from it, to the plain of Esdraelon below Mt. Tabor; it is broken by the passage of the Orontes and the Leontes. Its highest summits are 10,000 ft. above the sea. This chain contains the remnant of the ancient "cedars of Lebanon." Separated from this by a beautiful and fertile valley, Cœle-Syria, from 10 to 20 m. in width, is the Anti-Libanus chain, generally lower, though in its loftiest summit, Mt. Hermon, rivalling the highest peaks of the Lebanon range. E. of Hermon a chain of low mountains stretches eastward past Damascus; below it the country is hilly, and, viewed from the deep depression of the Jordan valley, seems mountainous. The mountains of Gilead E. of

the Jordan form the culminating point of these hills. Further E., in the Hauran, is a lofty table land, waterless, and with vast black bowlders and rocks scattered over its face. The most remarkable feature of the topography of Syria is the extraordinary depression of the valley of the Jordan. The valley of Cœle-Syria (now El-Bukaa), between the Libanus and the Anti-Libanus, is about 2,300 ft. above the sea; it formerly contained Heliopolis or Baalbek, and other great cities. Near its southern termination it divides into two branches, one cutting through the Lebanon range in the narrow gorge through which the Leontes finds its way to the sea, the other striking off southward and descending rapidly for 15 m. to the source of the Jordan at the base of Hermon. The continuation of the latter, the valley of the Jordan, descending with a steady but rapid slope, at the plain of Huleh is at the sea level; at the lake of Tiberias it is about 650 ft. below it; and within 60 m. of direct distance, though by the circuitous channel of the river 200 m., at the Dead sea, it is about 1,300 ft. below the Mediterranean. No similar river valley is known. Among the level tracts of Syria are the great plain of Esdraelon, that of Sharon, and the arid sandy plain of Gaza. Around Damascus, an oasis in the desert, vast plains of sand extend E. and S., and cover the region that contains the ruins of Palmyra.—The geology of Syria is interesting. In the extreme south are only primitive rocks, the variegated granite of the Sinaitic peninsula; the deep chasm of the Dead sea, with its bitumen pits, salt mountains, and warm springs, belongs to the carboniferous era; the calcareous and sandstone formations of Hermon and Lebanon abound in fossils of the era of the new red sandstone; and the porphyry and basalt of the Hauran give evidence of their igneous origin. The soil is exceedingly fertile wherever there are sufficient rains, or irrigation can be practised; but where there is no water, it is sandy and utterly barren. The region around the Dead sea is thoroughly impregnated with salt and alkalies, and is entirely devoid of vegetation. In the south and east there are vast sandy wastes. The mineral productions of Syria are iron of excellent quality, a little quicksilver and some coal in the south, and in the Dead sea region salt and bitumen. Good salt is also made on the shores of the Mediterranean.—There are few countries of the same extent in which the climate is so varied as in Syria. On the slopes of Lebanon it is cool and pleasant in the summer months, and in the winter heavy rains fall, but the cold is not severe. In the valley of the Jordan the summer heat is equal to that of the hottest portion of the tropics, and on the coast the summers are also very hot and unhealthful. In winter Beyrout and some of the other cities of the coast are favorable for invalids. In Jerusalem the heat is oppressive during the day in summer; rain seldom falls between the end of April and the beginning of October, and there are few clouds, and hence everything is parched till the rainy season. Damascus is colder in winter than the western slopes of Lebanon, and snow frequently falls; yet the orange and fig thrive there. The average range of heat in the hottest part of summer at Jerusalem and Damascus is from 84° to 86° F. In Aleppo the annual range is very great, the thermometer falling below zero in winter and rising above 100° in summer.—The implements and modes of agriculture are nearly identical with those in use 2,500 years ago. Still the crops, wherever there are rains or irrigation can be practised, are large. Wheat, barley, durra, and spelt are largely produced, as well as rice, lentils, peas, &c.; cotton, hemp, silk, madder, indigo, sesamum, castor oil, tobacco, potatoes, capsicum, melons, cucumbers, and artichokes are also important crops. Figs, olives, mulberries, grapes, almonds, apricots, peaches, pomegranates, oranges, lemons, dates, and other fruits abound. Vineyards are numerous on the mountain slopes and in the hill country of Judea; the grapes are large and luscious, and the wine made from them is excellent. Storax is produced for the market. In the vicinity of Damascus are extensive fields of roses, the petals of which furnish the attar of commerce. The sycamore, Indian fig, carob, mulberry, and pistachio trees grow abundantly, both wild and cultivated. Scammony and sumach are gathered about Mt. Lebanon for exportation. The cedar, pine, and fir are found in extensive forests on the mountains, though the true cedar of Lebanon, once so highly prized for building purposes, is nearly extinct. The arbutus, terebinth, laurel, and several species of juniper occur on the table lands, and also dwarf oaks which produce the best gall nuts. The domestic animals are horses, of which the wandering tribes possess breeds of extraordinary speed and beauty; cattle, generally small and inferior; asses and mules, large and very serviceable; sheep and goats of several kinds, the broad-tailed variety of the former being found only in N. Syria; camels throughout the country, and the domesticated buffalo on the coast and in the valley of the Orontes. Jackals, foxes, and hyænas are common in the desert mountains; the Syrian bear has his home in Mt. Lebanon; wolves and wild boars in the northern forests, and the latter also occasionally further S.; deer are also found in the north, and antelopes in the desert regions; and hares, porcupines, and jerboas are abundant. There are no poisonous serpents. Silkworms are reared extensively in the mountainous districts. Turtles and tortoises are found in considerable numbers. Fish are abundant in some of the inland lakes, though not plentiful along the coast of the Mediterranean. The manufactures are few and coarse. Beyrout is now the chief commercial city, and within 40 years its population has increased from 5,000 to 70,000.—

The inhabitants are of a great variety of races and religions. The ruling race are the Osmanli Turks, though they are but an insignificant portion of the Mohammedan population, who are mostly Arabs; they are bigoted and hostile to Christians, and are strict in their adherence to the Sunna or orthodox Islamism. There are four sects usually considered Mohammedan dissenters, though not all of them can properly be reckoned as Mohammedans. The Metualis are the followers of Ali, the son-in-law of Mohammed, and are allied to the Shiahs of Persia; they number about 30,000, and are found W. of the Orontes and on the S. part of the Lebanon range. The Ansaries or Nossairians, inhabiting the mountains extending from the N. extremity of Cœle-Syria to the gorge of the Orontes at Antioch, and numbering about 30,000, keep their religious views a secret. The Ismaëlians, occupying the mountains W. of Hamah, are few, and were originally Shiahs; they are the descendants of the people known in the time of the crusades as Assassins. The fourth sect is the Druses, in the Lebanon and Anti-Libanus, numbering about 70,000, and the most fanatical of all. The largest of the nominally Christian sects is that of the Maronites, who are found chiefly in the Lebanon, though they have small communities in all the principal towns from Aleppo to Nazareth. Their number in 1874 was about 140,000. (See ANSARIES, ASSASSINS, DRUSES, and MARONITES.) The orthodox Greeks (Greeks in religion, but not generally in blood), numbering about 150,000, are scattered throughout the cities and more level portions of Syria, and engage in agriculture and trade; they have their worship in their own language. There are dissenters also from the Greek church, the Syrians or Jacobites, a mere handful, dwelling mostly N. and N. E. of Damascus. The Greek Catholic and Syrian Catholic churches acknowledge the pope, though in some particulars they approach more nearly to the Greek than the Roman church; they are about 50,000 in all, and embrace a large number of the more wealthy Christians in Syria. The Armenians are 50,000 or 60,000 in number. There are about 25,000 Jews in Syria; those in Palestine are immigrants from foreign countries, while those of Aleppo and Damascus are descendants of Jewish families who have resided there for many centuries. There are Mohammedan schools in the cities, and the Christian sects also maintain some schools. The children of the wealthy are frequently sent to France or England for education, but the great mass of the people are very illiterate. Of late years, however, great improvements have been made in education by means of schools established by Greeks, Catholics, and especially by Protestant missionaries. —The central part of Syria is designated in the Hebrew Scriptures as Aram Dammesek, or the Aram of which Damascus was the capital. The empire of the kings of Damascus gradually extended eastward over a part of the plain of Mesopotamia and westward to the mouth of the Orontes. It was finally overthrown by the Assyrians under Tiglath-pileser, about 740 B. C. From the head waters of the Orontes southward, all of Palestine W. of the Jordan, and probably Gilead and the Hauran E. of it, were peopled by the Canaanites. The Phœnicians settled mainly along the coast of the Mediterranean, and became the earliest commercial nation of the world. Sidon, their first metropolis, is said by tradition to have been founded by Sidon, the oldest son of Ham; and colonies from it went forth to Tyre and Arvad (Aradus), and thence to all portions of the Mediterranean and beyond. Phœnicia attained its greatest power about 1050 B. C., and it enjoyed uninterrupted prosperity for full 300 years, but was at last conquered by the Assyrians, and subsequently by the Babylonians and Persians. The southern parts of western and portions of eastern Palestine were inhabited by a tall race, the Anakim and Rephaim, traces of whose cities yet remain in the Hauran. The S. W. coast was occupied by the Philistines, and the region adjoining the Dead sea to the east by the Semitic Ammonites and Moabites. (See PALESTINE.) The equally Semitic Israelites emigrated from Egypt to Palestine about 1500, or according to some authorities about 1300 B. C., and thenceforward for about 1,500 years exerted a powerful influence in its history. (See HEBREWS.) The theocracy under which they existed for several centuries was terminated by the election of Saul as king early in the 11th century B. C., and the kingdom was divided (about 975) in the reign of Rehoboam, the grandson of his successor David. The ten tribes, or Israel as they were distinctively termed, were conquered and carried into captivity by the Assyrians in 721, and their place was supplied by colonists from Babylonia, Hamath, and elsewhere, who became the Samaritans of a subsequent era, and a few families of whom still exist on their ancient site. The kingdom of Judah fell before Nebuchadnezzar 133 years later, but after a 70 years' captivity the people were restored to their own land, and the second temple was built. Syria from this period, until Grecian power became paramount there, was governed by a Persian satrap resident at Damascus. The battle of Issus, in 333, led to the subjection of Syria proper, Phœnicia, and Palestine to Alexander the Great. On his death, and after a long struggle of succession on the partition of his empire, the Ptolemies in Egypt received Palestine and Cœle-Syria, and Seleucus Nicator northern Syria. He founded Antioch, near the mouth of the Orontes, and made it his capital; and for several centuries it was the greatest of oriental cities. The kingdom of Syria continued flourishing under the Seleucidæ till the beginning of the 2d century B. C. Antiochus the Great wrested Palestine and Cœle-Syria from Egypt. The

revolt of the Jews under the Asmonean family against Antiochus Epiphanes, after a struggle of 25 years, ended in their independence (142). (See Antiochus, Demetrius Soter, Hebrews, and Seleucus.) About 63 B. C. Syria became a Roman province, and subsequently was divided into several provinces; the Herodian family ruled over Judea and some adjoining districts, while northern Syria and the coast were under Roman proconsuls. After the destruction of Jerusalem by Titus (A. D. 70), the whole of Syria, including Judea, was ruled by a Roman prefect, and Antioch was the capital. It continued under the Roman and Byzantine empire till its conquest by Chosroes II. in the beginning of the 7th century, followed by that of the Mohammedans in 632–'8. In 654 Damascus again became the capital of Syria, and in 661 of the great Mohammedan empire. The capital was removed to Cufah in 750, and afterward to Bagdad, and Syria thenceforth became only a province of the empire of the caliphs. About the middle of the 10th century the rival Mohammedan dynasty of the Fatimites in Egypt conquered it, and in the latter part of the 11th the Seljuk Turks made it a part of their empire. The cruelties perpetrated by these fanatics on Christian pilgrims visiting the Holy Land led to the crusades. Jerusalem was taken by assault (1099), and the whole of Syria except Damascus and a part of Mesopotamia conquered by the Christian princes, and divided into principalities. Godfrey was chosen ruler of Jerusalem, Bohemond reigned at Antioch, Baldwin at Edessa, and the count of Toulouse at Tripoli. Their rule was of short duration; after repeated attacks by Noureddin and his successors, it was overthrown by Saladin in 1187. The crusades which followed resulted only in their regaining a few points, in the temporary acquisition of Jerusalem by treaty in 1229, and the final occupation of the whole country by the Mamelukes in 1291. (See Egypt.) For a long period the country was the prey of the two contending Tartar powers, Tamerlane and his successors and the Mameluke sovereigns of Egypt. In 1517 it was conquered by Sultan Selim I., and from that time to our own it has formed a part of the Ottoman empire. In 1832 Ibrahim Pasha conquered Syria for his father Mehemet Ali, pasha of Egypt; but in 1841, after the armed intervention of England and her allies, it was restored to the sultan. In the summer of 1860 an insurrection occurred on the part of the Mohammedans at Damascus, in which many Christians were slain, the Dutch consul killed, and the American consul wounded. At the same time sanguinary disturbances, such as had frequently occurred before, broke out in Mt. Lebanon, between the Druses and Maronites, and a predatory conflict of several months' duration followed, in which nearly 150 villages were destroyed. France and England finally interfered, the outbreak was suppressed, and the prime movers were brought to punishment, but not until more than 15,000 men had been killed, and tens of thousands of people were homeless and destitute, and compelled to take refuge in the cities of the coast.

**SYRIAC LANGUAGE AND LITERATURE.** The Syriac language belongs to the northern branch of the Semitic family. (See Semitic Race and Languages.) It is an Aramaic dialect, which rose to a literary language under the name of Syriac in the Christian schools of northern Mesopotamia. In writing it various forms of character are used, all of them of kindred origin, and coming from the same source whence are derived the other Semitic alphabets. The oldest character is the Palmyrene, represented by sundry inscriptions dating from the time of Christ. Next in age is the Estranghelo alphabet, commonly employed by the Syrians till the 8th or 9th century. The common

modern Syriac alphabet is an adaptation of the Estranghelo to an easier and more rapid style of writing; it began to come into use in the 5th and 6th centuries, and by degrees crowded out its predecessor, which was at last employed only for headings and similar purposes. The Estranghelo is also the parent of the Cufic, from which the modern forms of the Arabic are derived. Finally, we have the Nestorian character, still in common use with modern Nestorian Christians; it is heavier and squarer than the last named, and less altered from their common mother, the Estranghelo. All the Syriac alphabets contain the same 22 characters with the Phœnician and the Hebrew. The Syriac contains many Greek and Latin words, chiefly nouns; it has also partly filled out the scanty structure of the Semitic verb with forms of periphrastic origin. Thus, besides the usual perfect and imperfect (or preterite and future), each of which is capable of standing for time past, present, or future, it has a distinctive present, formed by a participle and following pronoun; an imperfect, formed of a participle and the verb to be; a pluperfect, formed of the perfect (or preterite) and the verb to be; and even a future, with the adjective ready, about to. Of the Semitic conjugations, the Syriac has but three, each with its passive; the second and third are hardly distinguished in meaning, both expressing intensive or causative action. The dual number has entirely disappeared. The ancient Syriac was a vernacular dialect during the first centuries after Christ; after being raised to the rank of a cultivated literary language, it maintained itself as such, unaltered, throughout the whole period of growth of the Syriac literature; and it is still the sacred language of the scattered bodies of Christians in Asia representing the ancient Syriac church. It is no longer properly understood, however, even by the best instructed among them. The vernacular dialect of the once powerful and active sect of Nestorians has been lately, by the efforts of the American missionaries at Urumiah, raised to the rank of a printed language, with a Christian literature, school and scientific books, periodicals, &c. (See NESTORIANS, and PERKINS, JUSTIN.)—The Syriac literature is Christian, composed under Greek influence and after Greek models; and besides the important part it has played as the intermediary between Greek and Moslem science and philosophy, it is a source of valuable historical information. The oldest Syriac work still existing is the translation of nearly the whole Bible, of unknown authorship, commonly called the Peshito; it is supposed to have been made not later than about A. D. 200. The earliest authors whose names, with fragments of their works, have come down to us, are a few years older; they are Bardesanes and his son Harmonius. Besides philosophical works, they composed the first hymns in the language, and fixed its poetic style, giving it a properly metrical form, dependent on accent and number of syllables, with occasional rhyme; it was the first time that any Semitic dialect had been subjected to such rules. But the most prominent early Syriac author is St. Ephraem, or Ephraem Syrus, of the middle of the 4th century; with him begins the full career of the Syriac literature, which continued uninterrupted until the 9th century. A great part of this literature has been lost, and what remains has as yet been but partially worked up and made accessible. It may be said to have done its principal work in the 8th and 9th centuries, in introducing classical learning to the knowledge of the Arabs. The grammatical study and culture of the Syriac began after the founding of the famous school of Edessa, long a chief centre of oriental learning, in the 5th century. The works of previous laborers in this field were effaced by those of Jacob of Edessa, of the 7th century, whose authority gave the classical and sacred dialect its final form. From his time the series of native grammarians and lexicographers is almost unbroken; of most note among the former are Elias of Nisibis (11th century), John Bar-Zugbi (beginning of the 13th century), and Bar-Hebræus, known also as an Arabic author by the name of Abulfaraj (13th century); of the latter the most important are Bar-Ali and Bar-Bahlul, of the 9th and 10th centuries. Bar-Hebræus, who is distinguished by both his Syriac and Arabic works, and in various departments of knowledge, is the last great name in Syriac literary history. The study of Syriac was introduced into Europe in the 15th century, and the names of Ambrosius, Widmanstad, the two Ecchellenses, and Assemani are prominent among its cultivators. The only comprehensive dictionary is that contained in Castell's polyglot lexicon, and published separately by Michaelis (Göttingen, 1788). Of the Latin grammar of Hoffmann (Halle, 1827), an English abridged translation has been published by Cowper (London, 1858); it has also been worked over and much extended and altered by Merx (1867). The German one of Uhlemann (Berlin, 2d ed., 1857) includes also a chrestomathy and glossary; this, too, has been reproduced in English in this country by E. Hutchinson (2d ed., New York, 1875). Among the other chrestomathies published, the most useful are those of Rödiger (Halle, 1838) and Kirsch, edited with a glossary by Bernstein (Leipsic, 1832). A complete lexicon was begun by Bernstein, but interrupted by his death; his collections and Quatremère's have since passed into the hands of Dean R. Payne Smith, who is now (1876) publishing a very full and learned dictionary. Besides Dean Smith, Cowper and Cureton are the best English cultivators of the study, and the latter especially has done great service by the publication of extracts from the precious collection of MSS. some time since acquired for the British museum from the convent of St.

Maria Deipara in Egypt. A grammar of the dialect of Urumiah, by the Rev. D. T. Stoddard, was published in 1856 by the American oriental society. Nöldeke has produced a fuller and more learned one, founded on this and on the texts published by the missionaries, entitled *Grammatik der neusyrischen Sprache* (Leipsic, 1868). Dr. Adalbert Merx has published a *Neusyrisches Lesebuch: Texte im Dialekte von Urmia* (Breslau, 1874).

**SYRINGA.** See LILAC, and PHILADELPHUS.

**SYROS.** See SYRA.

**SYRTIS MAJOR** and **Syrtis Minor,** the ancient names of two large gulfs on the N. coast of Africa, now called respectively the gulf of Sidra and the gulf of Cabes or Gabes. These gulfs were dangerous on account of their shallowness, the number of quicksands, and the uncertainty of the tides. The Greater Syrtis, or gulf of Sidra, is on the N. coast of Tripoli, and extends from the promontory of Boreum (now Ras Teyonas) on the E. side to that of Cephalæ (Ras Kasr Hamet) on the W. The distance between the two promontories is about 270 m., and the greatest extension of the gulf inland is 110 m. The Lesser Syrtis, or gulf of Cabes, indents the E. coast of Tunis, between the island of Jerbah on the south and Caput Vadorum (Ras Kapudiah) on the north; its width is about 100 m., measuring from these points. The region between the two gulfs, formerly called Syrtica, is mostly a narrow sandy or marshy strip of land, now belonging to Tripoli. In ancient times it was peopled by the Lothophagi, Macæ, Psylli, Nasamones, and other Libyan tribes, besides Egyptians and Phœnicians on the coast. Cyrene and Carthage contended for it, the latter winning, it is said, through the self-sacrifice of two brothers, the Philæni.

**SZABADKA** (Ger. *Maria-Theresiopel*), a town of S. Hungary, in the county of Bács, 96 m. S. S. E. of Pesth; pop. in 1870, 56,323. Its inhabitants are mostly agriculturists, but there is also considerable trade in cattle, tobacco, and other products.

**SZABOLCS,** a N. E. county of Hungary, in the Trans-Tibiscan circle, the Theiss constituting the N. and part of the W. frontier; area, 2,304 sq. m.; pop. in 1870, 265,584, chiefly Magyars. It is a wide, sandy plain, with large marshes, especially in the north and west, but the soil is fertile. The chief products are cattle, grain, tobacco, and wine. Capital, Nagy-Kálló.

**SZALA.** See ZALA.

**SZALAY, László,** a Hungarian historian, born in Buda, April 18, 1813, died in Salzburg, July 17, 1864. He studied at the university of Pesth, was admitted to the bar in 1833, was a member of the diet of 1839-'40, and prepared with Deák and others the penal code adopted by the lower house. Having edited for some time the *Themis*, and subsequently the *Budapesti szemle* ("Buda-Pesth Review"), he succeeded Kossuth in July, 1844, as editor of the *Pesti hirlap* ("Pesth Journal"). In 1847-'52 he published *Statusférfiak könyve* ("The Book of Statesmen"), a collection of political biographies. In 1848 he was sent by the Batthyányi ministry as envoy to the provisional central government of Germany at Frankfort, whence he soon after retired to London, and subsequently resided in Switzerland, until allowed to return to Hungary about the beginning of 1861, where he became a prominent member of the diet at Pesth. His principal work is *Magyarország története* ("History of Hungary," 6 vols., Leipsic and Pesth, 1850-'63; German ed., 1866 *et seq.*).

**SZATMÁR,** or **Szathmár. I.** A N. E. county of Hungary, in the Trans-Tibiscan circle, bounded N. by the Theiss, and intersected by the Szamos; area, 2,260 sq. m.; pop. in 1870, 280,568, chiefly Magyars. The E. part is mountainous, and contains the gold and silver mines of Nagy-Bánya; the remainder is level and partly marshy. The climate is healthful and mild, and the soil fertile, producing corn, maize, hemp, flax, wine, and tobacco. Cattle, swine, sheep, and bees are raised in great numbers. **II.** A town, capital of the county, 65 m. E. N. E. of Debreczin; pop. in 1870, 18,353. It consists of two parts, Németi on the N. bank of the Szamos, and Szatmár on an island in the river. It is the seat of a Catholic bishop, and has a Catholic gymnasium, a lyceum, a seminary, and Greek and Protestant churches. A considerable trade is carried on in wine, linen, and woollen fabrics.

**SZÉCHENYI, István,** count, a Hungarian statesman, born in Vienna, Sept. 21, 1791, died by his own hand at Döbling, April 8, 1860. He was the son of Count Francis Széchenyi, the founder of the national museum at Pesth, served in the last campaigns of Austria against Napoleon, and in 1825 took his seat in the upper house of the Hungarian diet. He contributed the sum of $30,000 toward the foundation of the Hungarian national academy, and was its vice president; and as leader of the national party he carried through a grand series of public enterprises. To popularize his schemes of reform, he published *Hitel* ("Credit," Pesth, 1830), and *Világ* ("Light," 1832). Frightened by Kossuth's radical agitation, he wrote against him his *Kelet népe* ("People of the East," 1840), and combated him in the diet of 1847; but in 1848 he yielded to the current, and entered the Batthyányi-Kossuth cabinet as minister of public works. On the outbreak of the war he became insane, and was taken to an asylum at Döbling near Vienna, in which, though he recovered after some time, he spent the remainder of his life. In March, 1860, his abode and papers were searched by the Austrian police, and shortly after he shot himself.

**SZEGEDIN** (Hun. *Szeged*), a city of Hungary, capital of the county of Csongrád, on the right bank of the Theiss, opposite the mouth of the Maros, 55 m. W. of Arad and 96 m. S. E. of Pesth; pop. in 1870, 70,179, chiefly Magyars

and Slavs. It stands in a marshy plain, and is divided into the town proper and the upper and lower suburbs. The river is crossed by a bridge of boats, and the town is defended by an old fortress built by the Turks in the 16th century, which contains extensive barracks, a house of correction, and a church of its own. There are six Roman Catholic churches, a Catholic gymnasium, and a beautiful Greek church. Cloth, tobacco, soda, and soap are manufactured, and river boats are built. It is connected by rail with all parts of the country, and carries on an extensive trade. In the summer of 1849 it was the seat of the Hungarian diet till it was taken by the Austrians early in August.

**SZEKLERS.** See Transylvania.

**SZOLNOK. I. Middle,** a county formerly belonging to Transylvania, and now to Hungary, bounded S. E. by Transylvania; area, 855 sq. m.; pop. in 1870, 113,639, chiefly Wallachs. It is mountainous, and watered by tributaries of the Szamos. Capital, Szilágy-Somlyó. **II.** A town of Hungary, in the county of Heves, on the Theiss, 56 m. E. S. E. of Pesth; pop. in 1870, 15,847, chiefly Magyars. It is connected with Pesth, Arad, and Debreczin by rail, and has considerable trade and important fisheries.

# T

T, THE 20th letter and 16th consonant of the English and other alphabets derived from the Roman, the 19th of the Greek (*tau*), and the 9th of the Hebrew (*teth*). It is of the denti-lingual class, and represents the sound produced by a forcible emission of the breath after placing the tongue against the roof of the mouth near the roots of the teeth. This forcible emission of the breath is the principal distinction between the sounds of *t* and its sonorous counterpart *d*. In etymology it is interchangeable with *d*, and sometimes with *th*, *p*, *s*, and *l*. By itself it has but one sound; but combined with *h*, it forms a simple sound, hard or soft in quality, distinct from that of either component; as the *th* in *thigh*, which the Anglo-Saxons represented by ð, the Greeks by $\theta$ (*theta*), and the Hebrews by ת (*tav*); or as in *thy*, which the Anglo-Saxons represented by þ. This sound is wanting in all the other European languages except Spanish (*d*, *z*, and *c* before *e* or *i*), modern Greek ($\theta$ and $\delta$), Danish (*d* between vowels, very faint), and Welsh (*dd*). In French *t* is dropped in many words from the Latin where it is preceded and followed by a vowel; as in *père*, *mère*, *vie*, from *pater*, *mater*, *vita;* also from the termination of many words. In English, before *i* and another vowel, *t* has the sound of *sh*, as in *nation;* in French, of *s;* in German, of *tz.*—As a Greek numeral $\tau$ stood for 300, $\,_{,}\tau$ for 300,000. Among the Latins T represented 160, and with a dash above it ($\bar{T}$) 160,000. As an abbreviation it stands for *theologia*, as in S. T. D., *sacræ theologiæ doctor;* and in ancient writings, monuments, or coins, for Titus, Titius, Tullius, and sometimes *tribunus.* (See D.)

**TABASCO,** a S. E. state of Mexico, bounded N. by the gulf of Mexico, E. by Campeachy, S. by Guatemala and Chiapas, and W. by Vera Cruz; area, 12,716 sq. m.; pop. in 1871, 83,707, chiefly Indians. The coast is indented by several bays and lagoons, and there are islands toward its N. E. extremity, the most important of which are Laguna, Carmen, and Puerto Real. The surface is generally flat and in some places marshy, and there are several small lakes. The rivers, with the exception of the Usumasinta and Tabasco, are generally small, and they all overflow at certain seasons. The climate is hot and unhealthful; and between September and March gales render navigation dangerous even on the rivers. Oak, cedar, ironwood, and mahogany abound. Cacao, coffee, pepper, sugar cane, palmetto, tobacco, maize, and rice are cultivated; in some places indigo grows spontaneously; and wild bees afford large supplies of wax and honey. Capital, San Juan Bautista.

**TABERNACLE** (Lat. *tabernaculum*, tent; Heb. *ohel*), the sanctuary which the Israelites carried with them through the desert, and which, after the conquest of Canaan, was set up in various towns of Palestine until the time of Solomon, when it was replaced by the temple of Jerusalem. It was constructed, by order of Moses, by Bezaleel and Aholiab, and set up for the first time on the first day of the first month in the second year after leaving Egypt. Its framework consisted of 48 perpendicular gilded boards of acacia wood, which were kept together by golden rings and fixed into silver sockets. Over these boards four coverings were spread. The entrance, at the east end, was closed by means of a splendid curtain, supported by five columns. A curtain divided the interior into two rooms, the sanctuary and the holy of holies. In the sanctuary was placed, on the north, the table with the 12 loaves of shew bread (see Shew Bread); toward the south the golden candlestick; and in the middle the altar of incense. In the holy of holies stood the ark of the covenant. The tabernacle was surrounded by a kind of courtyard which was 100 cubits long and 50 cubits wide. The typical significance of the tabernacle has been, ever since the times of Philo and Josephus, a subject of investigation. The most important treatises on the subject in modern times are by Creuzer, *Symbolik des mosaischen Cultus* (2 vols., Heidelberg,

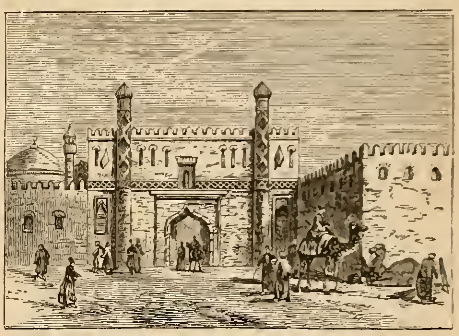
1837–'9), and Friedrich, *Symbolik der mosaischen Stiftshütte* (Leipsic, 1841).

**TABERNACLES, Feast of** (Heb. *'hag hassukoth*), one of the three great festivals of the Jews, observed after harvest, and beginning on the 15th day of the month Tisri. It commemorated God's protecting care over his people while they dwelt in the wilderness. It was also a harvest feast or thanksgiving. It continued eight (among the exiled Jews nine) days, the first and last (in exile the first two and last two) of which were the most important. To the ceremonies of the festival belongs the waving toward the four quarters of the world of fine fruits and leafy branches, with the singing of liturgical songs, commonly called, from the repetition of the words *hosia' na* (Oh save!), Hosanna. On the seventh day this was repeated, for the last time, with greater solemnity. During the first seven days the living in booths was obligatory, which is still partially observed by the Jews in most countries. Sacrifices took place in the temple, and in later times also a ceremony of "pouring water" on the sacrifice, and a great illumination of the outer court, with dances by torchlight.

**TABOR, Mount** (Gr. *'Αταβύριον*; now *Jebel et-Tur*), an insulated eminence in the plain of Esdraelon, about 6 m. S. E. of Nazareth, in Galilee, commonly regarded as the scene of the transfiguration of Christ. It is about 1,800 ft. high, composed entirely of limestone, and its sides are covered up to the summit with the valonia oak, wild pistachios, myrtles, and other shrubs. Its summit is a plateau about 600 yards in extent from N. to S. and 300 yards across. All around this plain are traces of an ancient wall, and below it on the S. E. side of the hill are the ruins of a fortification, a gateway of Saracenic architecture called "the gate of the wind," and a small vault where the Latin monks from Nazareth annually celebrate the transfiguration. Among the ruins of a church on the N. side of the mountain the Greeks observe the same festival. Tabor is several times mentioned in the Old Testament, and upon it Deborah and Barak assembled the warriors of Israel previous to the battle with Sisera. There was upon it a city of the Levites of the tribe of Zebulon, which was taken and fortified by Antiochus the Great, 218 B. C. In 55 B. C. a battle was fought near it between the Romans under the proconsul Gabinius and the Jews under Alexander the son of Aristobulus, in which 10,000 Jews were slain. Tabor is not named in the New Testament, and was first mentioned as the place of the transfiguration in the 4th century. At the foot of it the crusaders several times fought the Moslems, and Napoleon gained a victory over the Turks.

**TABORITES.** See HUSSITES.

**TABRIZ, Tebriz,** or **Tauris,** a walled city of Persia, capital of the province of Azerbijan, in lat. 38° 4′ N., lon. 46° 15′ E., near the river Aji; pop. about 120,000. It stands on a wide plain, 4,944 ft. above the sea, enclosed on all sides but the west by low mountains or hills. The vicinity is very fertile, and beautified by innumerable fruit gardens, celebrated for their peaches and apricots, and producing grapes from which is made a wine resembling Marsala. The wall of sun-dried bricks is about 3½ m. in circuit. The streets are narrow and tortuous, and the houses low and flat, but there is a large square, and the bazaars are numerous and spacious. The most remarkable buildings are the citadel, a lofty structure with massive brick walls; the Blue mosque, built in the 17th century by Abbas the Great, but now in ruins; and the villa of the heir apparent to the Persian throne, who resides here as governor of Azerbijan. Tabriz is one of the most important commercial cities in Persia. It is on the caravan route between the interior and Trebizond and Tiflis, and carries on a large foreign trade, also maintaining manufactories



City Gate, Tabriz.

of silk and cotton goods.—According to Persian tradition, Tabriz was founded by Zobeida, wife of Haroun al-Rashid; but the town existed in antiquity, and under the name of Gazaca was the capital of the Median province of Atropatene. At a later period it was the capital of Tiridates III., king of Armenia. It was visited by Marco Polo about 1293, and in 1320 there appear to have been Venetians settled there, and a Genoese factory in 1341. The present number of European inhabitants probably does not exceed 100. Tabriz has frequently been captured by the Turks, and it has often been damaged by earthquakes. The Anglo-Indian telegraph line passes through the city.

**TACHÉ, Alexandre,** a Canadian archbishop, born at Kamouraska, Lower Canada, in 1822. He graduated at the college of St. Hyacinthe, became an Oblate of the Immaculate Conception, and in 1843 asked to be sent to the Red River mission. He was ordained priest at St. Boniface, and devoted himself to the Indian tribes beyond the civilized regions of Canada, especially along the valley of the Saskatchewan. He was among the first to penetrate into the unexplored portions of the northwestern territory, and contributed toward the colonization and progress of Manitoba. He was consecrated

coadjutor to Bishop Provencher of St. Boniface, Nov. 23, 1851, and succeeded him, June 7, 1853. In September, 1871, he was made metropolitan. During the troubles attendant on the Riel insurrection in 1869–'70 he exerted his influence to prevent the effusion of blood; and after the surrender of Riel and the latter's election to the Dominion house of commons, the archbishop resisted successfully all attempts of the authorities to punish him as a traitor. He has established a college and theological seminary at St. Boniface, opposite Fort Garry, and, besides numerous interesting reports on the Indian missions printed in the "Annals of the Propagation of the Faith," has published *Vingt années de missions dans le nord-ouest de l'Amérique* (Montreal, 1866), and *Esquisse sur le nord-ouest de l'Amérique* (1869).

**TACITUS, Caius Cornelius**, a Roman historian, born probably about A. D. 55, died probably after the accession of the emperor Hadrian (117). He was early appointed to a public office under Vespasian, and married a daughter of Julius Agricola. He held a prætorship under Domitian, and was *consul suffectus* under Nerva. Nothing positive is known of his subsequent career. He was famous as an orator and a lawyer, and the rhetorical studies of his earlier years led him to compose his first work, the *Dialogus de Oratoribus*, which contrasts strongly with his later writings for diffuseness and negligence. His *Vita Julii Agricolæ* is the masterpiece of ancient biography, and specially valuable for the account it gives of the early condition and history of Britain. The *Germania* (*De Origine*, *Situ*, *Moribus ac Populis Germaniæ*) appeared soon after, both probably in 98. It is based on the works of Pliny and the most trustworthy sources obtainable at the time, and as such is of great importance to students of German antiquities. Numerous theories have been broached in regard to the author's purpose in writing it, but there is every reason for supposing that one of his main objects was to remind the Romans of the virtues of their former days, and to warn them of the dangers threatening them from the north. Its geographical and historical accuracy has often been attacked, and as often successfully vindicated, though he has frequently exaggerated or idealized the customs and morals of the German people. About the year 105 appeared the first portion of his history of Rome after the time of Augustus, embracing *Historiæ* of the years 69–96, or from the last days of Galba to the death of Domitian. Only the first four books and a part of the fifth, reaching to the year 70, are extant. Next appeared the *Annales*, a concise history of the events from 14 to 68. Its original title was *Ab Excessu D. Augusti Libri.* Of the original 16 books, only nine complete and parts of three others are extant. The portions relating to the last two years of Nero are wanting. Tacitus is commonly compared to Thucydides; but the latter has none of the psychological characteristics of the former. There is a greater resemblance between Tacitus and his forerunner Sallust. His style is remarkable for its vigor and conciseness. A melancholy and almost tragic earnestness pervades his pictures of imperial history. Numerous interpolations disfigure his writings, especially the last portion of the *Annales* and the *Historiæ*. The *editio princeps* of Tacitus, which is far from complete, was printed at Venice in 1469 by Vindelin de Spira; and of the numerous subsequent editions that of Ernesti (Leipsic, 1752), successively revised by Oberlin, Bekker, Walther, Ruperti, and others, and Halm's (Leipsic, 1874), are esteemed the best. The best translations are: in German, by Roth (Stuttgart, 1855–'7); in French, by Louandre (Paris, 1858) and Dureau de la Malle (1874); and in English, by Church and Brodribb (London, 1864). German literature abounds with hermeneutical treatises on Tacitus; Pfitzner's *Die Annalen des Tacitus kritisch beleuchtet* (Halle, 1869) is very thorough.

**TACITUS, Marcus Claudius**, a Roman emperor, born at Interamna (now Terni), Umbria, about A. D. 200, died at Tyana, in Cappadocia, in April, 276. Previous to the assassination of the emperor Aurelian in March, 275, he held various important civil offices, the last being that of consul in 273, and was well known for his love of letters, his great wealth, and his integrity. In September, 275, Tacitus was unanimously elected emperor by the senate. He instituted a few domestic reforms, and attempted to revive the authority of the senate, but died within little more than half a year from the commencement of his reign. According to one account, he was assassinated by his soldiers when on an expedition against the Goths in Asia Minor. He claimed descent from the historian Tacitus, whose works he ordered to be placed in all public libraries, and to be multiplied to the extent of ten copies a year at the public expense.

**TACKMAHACK, or Balsam Poplar.** See POPLAR.

**TACONIC SYSTEM, or Taghkanic.** See UNITED STATES (geological part).

**TADEMA, Lourenz Alma**, a Dutch painter, born at Drouryp, West Friesland, Jan. 8, 1836. He studied under Leys at Antwerp in 1861, and became known as a painter of classical subjects. His wife, the countess Pauline Dumoulin, died in 1869, and in 1870 he married an English woman and removed to London. His works include "Venantius Fortunatus and Radegond" (1862), "How they enjoyed themselves in Egypt 3,000 Years ago" (1863), "The Mummies" (1867), "The Siesta of Ancient Romans" (1868), "The Vintage Celebration at Rome" (1870), "The Last Plague of Egypt" (1872), and "The Picture Gallery" (1874).

**TADMOR.** See PALMYRA.

**TADOLINI, Adamo**, an Italian sculptor, born in Bologna in 1789. He studied in the academy of Bologna, and settled in Rome. In 1812 he received for his "Dying Ajax" the grand

prize instituted by Canova, under whose direction he executed from 1813 to 1820 many works, including a statue of Washington. His subsequent productions comprise "Venus and Amor," "The Abduction of Ganymede," "Francis de Sales," "A Bacchante," and "The Archangel St. Michael," a colossal marble group for which an American is said to have paid $40,000 (1869).

**TADPOLE.** See FROG.

**TAEL,** a Chinese measure of weight, equal to 1⅓ oz. avoirdupois. The Chinese government does not coin gold or silver. All payments are made in bullion or foreign coins, by weight; hence the tael (Chin. *liang*) has become a money of account, and 720 taels are received at Hong Kong and Shanghai as equivalent to 1,000 Mexican dollars. Taking the value of the Mexican dollar as fixed by the secretary of the treasury of the United States, Jan. 1, 1875, the tael would be equivalent to 1·386 United States dollar. The name is sometimes applied to the money of Japan, Siam, and Sumatra, and is probably of Malay origin.

**TÆNARUM.** See CAPE MATAPAN.

**TAFILET,** or **Tafilelt,** a division of Morocco, consisting of the oasis of the same name, lying S. E. of the Atlas mountains, between lat. 30° 45′ and 31° 10′ N. and lon. 3° 3′ and 3° 25′ W.; pop. estimated at 100,000. The oasis of Tissimi lies N. of it, and that of Sahra N. E. Tafilet is a fertile plain watered by two rivers, both of which are lost in the sands of the desert. Rain seldom falls. Wheat and barley are cultivated on the banks of the rivers, but dates are the chief product. Large herds of sheep and goats are kept, and stuffs and carpets are manufactured. There are mines of lead and antimony. The oasis is divided into five districts, Sfalet, Rhorfa, Iffli, Shiffa, and Tannajiut. The most important town is Abuam, about 240 m. E. S. E. of Morocco, but the official centre is Rissani, a few miles N. E. of Abuam. The inhabitants are mostly Shelloohs. A considerable trade is carried on with other parts of Morocco and with Algeria.—Tafilet, which is mentioned by the earliest Arab chroniclers, is probably identical with the kingdom of which Sigilmessa, founded A. D. 759, was the capital. In 1648 a king of Tafilet founded the dynasty which still rules Morocco.

**TAGANROG,** a city of southern Russia, in the government of Yekaterinoslav, on a promontory formed by the sea of Azov, 18 m. from the mouth of the Don and 27 m. N. W. of Azov; pop. in 1867, 25,027, including many Armenians and Greeks. It is strongly fortified, and despite the shallowness of the harbor it is the principal port of the sea of Azov. The exports in 1873, chiefly wheat, amounted to 28,797,839 rubles, and the imports to 8,048,663. The town has four large squares. The principal buildings are the cathedral, the admiralty, the marine hospital, the quarantine, the exchange, the theatre, and the palace near the Greek monastery of Jerusalem, built by Alexander I., who died and has a monument here. It was originally founded in 1696, but the present city dates from 1768. Taganrog was much damaged in 1855 by the bombardment from French and English gunboats, as well as the neighboring seaport Mariupol (founded in 1779 by Greeks; pop. about 6,000), which is under the municipal authority of Taganrog.

**TAGLIACOZZI.** See TALIACOTIUS.

**TAGLIONI. I. Filippo,** an Italian ballet master, born in Milan in 1777, died near the lake of Como, Feb. 11, 1871. He was successively connected with the theatres at Stockholm, Cassel, and Warsaw till 1853, when he returned to Italy. The most celebrated of his numerous ballets is the "Sylphide." He married a daughter of the Swedish tragedian Karsten. **II. Maria,** a dancer, daughter of the preceding, born in Stockholm about 1804. In 1822 she first appeared at Vienna, in 1827 at Paris, and in 1832 at Berlin. In the last year she married Count Gilbert de Voisin. She retired in 1847, and has since lived at her villa on the lake of Como, or in one of her palaces at Venice. She gained her greatest triumphs in *La bayadère*, *La Sylphide*, and *La fille du Danube*. **III. Paul,** brother of the preceding, born in Vienna about 1808. After performing with his sister in various theatres, he married the dancer Amalia Galster, with whom he made tours in Europe and the United States. His career as a dancer ended in 1847, when he became ballet master at the royal theatre in Berlin. He has since produced *Sardanapal*, *Undine*, and other celebrated ballets.—His daughter MARIA, born in Berlin in 1834, excelled as a dancer, but in 1866 retired from the stage, on her marriage with Prince Joseph Windischgrätz.

**TAGUS** (Span. *Tajo;* Port. *Tejo*), a river of Spain and Portugal, the longest in the peninsula, and dividing it into two nearly equal parts. It rises in the Sierra de Cuenca, in the province of Teruel near the border of Guadalajara, and flows N. W. for about 35 m.; then nearly W. 20 m., receiving the waters of the Molina; then S. W. a little more than 70 m., the Guadiela and other streams augmenting it; then nearly W. till it becomes for about 20 m. the boundary of Portugal, its principal affluents being the Jarama, Cedron, Guadarrama, Alberche, and Alagon. Entering Portugal, it inclines more and more to the southwest, receiving below Abrantes the Zezere, and from that point is navigable for vessels of 150 tons. In the lower part of its course are numerous islands, and for about 20 m. it spreads out into a table-like basin, 8 m. or more in width; but as it approaches Lisbon the hills on either side close up the valley, and at its mouth it is not over a mile wide. The banks of the Tagus are generally rugged and precipitous, and the adjacent plains are dry and barren. Lisbon, Santarem, and Abrantes in Portugal, and Talavera de la Reyna, Toledo, and Aranjuez in Spain, are on its banks. Its length is about 540 m.

**TAHITI.** See SOCIETY ISLANDS.

**TAHLEQUAH,** the capital of the Cherokee nation, Indian territory, in the valley of Illinois river, a tributary of the Arkansas, 170 m. W. N. W. of Little Rock, Ark., and 15 m. E. of the Missouri, Kansas, and Texas railroad; pop. about 300. The capitol, of brick, cost $20,000. There are two schools and a weekly newspaper (Cherokee and English).

**TAILLANDIER, René Gaspard Ernest.** See p. 905.

**TAINE, Hippolyte Adolphe,** a French author, born in Vouziers, April 21, 1828. He was educated at the Bourbon college, was connected with the normal school of Paris for five years, and since 1864 has been professor of the history and æsthetics of art in the school of fine arts. His *Essai sur Tite Live* (1854) received a prize from the French academy. His other works are: *Voyage aux eaux des Pyrénées* (1855); *Les philosophes français du XIX^e siècle* (1856); *Essais de critique et d'histoire* (1857; second series, 1865); *La Fontaine et ses fables* (1860); *Histoire de la littérature anglaise* (4 vols., 1864); *Idéalisme anglais: étude sur Carlyle* (1864); *Le positivisme anglais: étude sur Stuart Mill* (1864); *Philosophie de l'art* (1865); *Philosophie de l'art en Italie* (1866); *Voyage en Italie* (2 vols., 1866); *Notes sur Paris* (1867); *L'idéal dans l'art* (1867); *Philosophie de l'art dans les Pays-Bas* (1868); *De l'intelligence* (2 vols., 1869); *Philosophie de l'art en Grèce* (1870); and *Notes sur l'Angleterre* (1874). Most of his works have been translated into English by Durand, Van Laun, Haye, Rae, Fiske, and Stevens. In 1875 Taine began the publication of *Les origines de la France contemporaine*, with a volume on the *Ancien régime*, which is to be followed by one on the revolution.

**TAIPING.** See CHINA, vol. iv., p. 463.

**TAIT, Archibald Campbell,** an English clergyman, born in Edinburgh, Dec. 22, 1811. He was educated at the university of Edinburgh and at Balliol college, Oxford, and was afterward public examiner of the university. He was prominent in the opposition to the tractarians. In 1842 he succeeded Dr. Arnold as head master of Rugby school, where he remained eight years. In 1850 he was made dean of Carlisle, in 1856 bishop of London, and in 1868 archbishop of Canterbury. He has published "The Dangers and Safeguards of Modern Theology" (London, 1861), "The Word of God and the Ground of Faith" (1863), and two volumes of sermons.

**TAIT, Peter Guthrie,** a British mathematician, born about 1825. He graduated at Cambridge, was fellow of St. Peter's college, became professor of mathematics in Queen's college, Belfast, and in 1862 was elected professor of natural philosophy in the university of Edinburgh. He has published "A Treatise on Dynamics of a Particle," in conjunction with William J. Steele (8vo, Cambridge, 1856); "Value of the Edinburgh Degree, an Address" (8vo, Edinburgh, 1866); "Elementary Treatise on Quaternions" (8vo, Cambridge, 1867); and "Thermodynamics" (8vo, Edinburgh, 1868). He has also, in conjunction with Sir William Thomson, published an "Elementary Treatise on Natural Philosophy" (8vo, London, vol. i., 1867).

**TALAVERA DE LA REYNA** (anc. *Talabriga*), a town of Spain, in the province of Toledo, on the Tagus, 64 m. S. W. of Madrid; pop. about 9,000. It is a place of great antiquity, and was the scene of many conflicts between the Moors and Christians. On July 27 and 28, 1809, a battle was fought in the immediate vicinity, between the French, under Victor, Jourdan, and Sebastiani, and the British, under Sir Arthur Wellesley. In the decisive contest of the 28th, 30,000 French were driven back by 16,000 British troops.

**TALBOT. I.** An E. county of Maryland, bounded W. by Chesapeake bay, and S. and E. by the Choptank river; area, 250 sq. m.; pop. in 1870, 16,137, of whom 6,666 were colored. The surface is generally level, and the soil highly fertile. The Maryland and Delaware railroad terminates at the county seat. The chief productions in 1870 were 302,078 bushels of wheat, 515,122 of Indian corn, 38,825 of oats, 41,770 of Irish and 10,725 of sweet potatoes, 29,695 lbs. of wool, 99,008 of butter, and 990 tons of hay. There were 3,298 horses, 3,309 milch cows, 3,678 other cattle, 6,044 sheep, and 9,411 swine; 3 manufactories of carriages and wagons, 5 of clothing, 3 ship yards, and 7 saw mills. Capital, Easton. **II.** A W. county of Georgia, bounded N. E. by Flint river and drained by several large creeks; area, 524 sq. m.; pop. in 1870, 11,913, of whom 7,157 were colored. The surface is hilly and the soil good. It is crossed in the southeast by the Southwestern railroad. The chief productions in 1870 were 18,372 bushels of wheat, 200,645 of Indian corn, 12,940 of oats, 27,786 of sweet potatoes, and 7,020 tons of hay. There were 631 horses, 1,325 mules and asses, 2,021 milch cows, 3,435 other cattle, 1,093 sheep, and 9,308 swine. Capital, Talbotton.

**TALBOT, William Henry Fox,** an English author, born at Chippenham, Wiltshire, Feb. 11, 1800. He was educated at Harrow and Cambridge, represented the liberal interest of Chippenham in the first reform parliament, 1832–'4, and became high sheriff of Wiltshire in 1840. In 1833 he began the experiments which in 1840 resulted in the discovery which laid the foundation for the photographic art. (See PHOTOGRAPHY.) For this discovery he received in 1842 the medal of the royal society; and although he patented his process, he left it open to the public. Of late years he has devoted himself to deciphering cuneiform inscriptions. He has published "Legendary Tales in Verse and Prose" (London, 1830); "Hermes, or Classical and Antiquarian Researches" (2 parts, 1838–'9); "Antiquity of the Book of Genesis" (1839); "The Pencil of Nature," in which he details his experiments and discoveries in photography (6 parts, 1844–'6); and "English Etymologies" (1846).

**TALC**, a silicious mineral occurring in two forms, crystalline and massive. The massive variety was formerly called steatite (soapstone), and was regarded as a distinct species; but it has the same chemical composition as crystalline talc, viz., $4MgO,5SiO_2\frac{3}{2}H_2O$, or silica 62·14, magnesia 32·92, and water 4·94 per cent., being a hydrous silicate of magnesia. Talc is commonly in the form of lamellar crystals, which cleave perfectly in one direction, but are usually too incompletely developed to allow of an exact determination of their crystalline system; but hexagonal prisms and plates are occasionally found. They are optically biaxial. The lamellæ are very flexible but not elastic, and are unctuous to the touch. Talc is very soft, being only 1 on the scale of 10; sp. gr. from 2·6 to 2·8; lustre pearly; color apple-green to white, also greenish gray to dark green, subtranslucent. Talc, either in a foliated or lamellar form, or massive as steatite, is common, forming extensive beds in some localities. It is often associated with serpentine, talcose, or chloritic schist. Steatite or soapstone is known in different localities as potstone (*Topfstein*), *lapis ollaris*, rensselaerite, and French chalk (*craie de Briançon*). There are extensive quarries at Grafton, Athens, Westfield, and Marlborough, Vt.; at Francestown, Pelham, and Keene, N. H.; at Middlefield, Chester, and other places in Massachusetts; in Maryland near Baltimore, in Virginia near Washington and in Loudon co., and in Guilford co., N. C., and numerous other places, in metamorphic rocks. It is used for making stoves, ovens, and hearths; for sizing-rollers in cotton factories, on account of its not being affected by acids; and sometimes as a lubricant for journals. It is also used for slate pencils and crayons, and for the stoppers of chemical vessels. The American aborigines use it for culinary articles, and the Chinese for the carving of idols.

**TALENT** (Gr. *τάλαντον*; Lat. *talentum*), a term originally applied by the ancient Greeks to a balance for weighing, afterward to the substance weighed, and finally to the weight itself. In the system of weights in use the talent was the highest denomination, and was equivalent to 60 minas, each of which was equal to 100 drachmas, and each of these to 6 oboli. The values of these weights remained constant in relation to each other, while that of the units of the measure varied in different times and in different places. The system of money being based upon the weight of silver, the names of the weights employed came to be used as money values, in the same way as the English pound originally represented a pound weight of silver. No coins however are known to have been made larger than the tetradrachma, and the mina and talent were moneys of account only. The determination of the weights of the different talents in terms of our modern standards is a subject involved in great difficulty, and there is a marked disagreement among scholars. The oldest talent was the Babylonian, which was carried into the Phœnician and Grecian countries, and may with great probability be assumed as identical with the oldest Greek talent, called the Æginetan. The Hebrew talent differed but little if at all from this. The Euboic talent, also probably derived from the East, was in use in Attica previous to the time of Solon, and is often called the old Attic; it continued in use after the time of Solon, and hence was also called the commercial talent. Solon, in order to relieve the debtor class, reduced the talent so far as money was concerned, and the talent established by him, called the new Attic or Attic silver talent, is the one always meant in the classical authors when the context does not indicate a different one. The ratio of these talents to each other was as follows, in whole numbers: 15 Æginetan talents were equal to 18 Euboic or commercial talents, and to 25 Solonian or Attic silver talents. Their weights compared with our avoirdupois weight were probably as follows: the Æginetan equalled 95 lbs.; the Euboic, 79 lbs. 2 oz. 291·63⅓ gr.; the Attic silver talent, 57 lbs. The value of these talents in pure silver, taking the American trade dollar, containing 378 gr. of pure silver, as the standard, would be as follows: the Æginetan talent equals $1,759 26; the Euboic, $1,466 05; the Attic silver talent, $1,055 56. The coins in actual use fell below this standard both in weight and in purity, and varied in different ages. For approximate calculation the coin value of the above named talents may be assumed as equal to $1,700, $1,400, and $1,000 respectively. Various other talents are named by the ancient writers, the comparative values of which have been treated in the works of Böckh and of Hussey. The gold talent of the Greeks, or the Sicilian talent, the one always meant in Homer, contained about ¾ oz. and 71 gr. avoirdupois of gold.

**TALFOURD, Sir Thomas Noon**, an English author, born at Doxey, a suburb of Stafford, Jan. 26, 1795, died in Stafford, March 13, 1854. He was called to the bar in London in 1821, and in 1833 was made serjeant at law. From 1835 to 1841 he was member of parliament for Reading, and again from 1847 to 1849, when he was made a judge of the court of common pleas. In parliament he was distinguished by his efforts in behalf of the rights of authors, for whose benefit he introduced in 1837 the copyright act which, somewhat modified, was passed in 1842. His tragedy of "Ion" (1835) was acted with great success under the direction of Mr. Macready, and was followed by "The Athenian Captive" (1838), "Glencoe" (1840), and "The Castilian" (1854). The last was not acted, and "The Athenian Captive" and "Glencoe" were but moderately successful on the stage. His other works include memoirs and correspondence of his friend Charles Lamb (1837 and 1838, subsequently published as one work), and "Final Memoirs" (1848).

**TALIACOTIUS, Gasparo** (TAGLIACOZI, or TAGLIACOZZIO), an Italian surgeon, born about 1546, died in Bologna, where he was professor of anatomy and surgery, in 1599. He attained high renown for his medical lectures, but is now mainly remembered for what has been named from him the Taliacotian operation for the restoration of lost noses, ears, &c. Though this operation was not original with him, yet he carried it to greater perfection and was more successful than any of his predecessors. His process was fully detailed in his work *De Curtorum Chirurgia per Insitionem Libri II.* (2 vols. fol., Venice, 1597; new ed., Berlin, 1831). (See AUTOPLASTY.)

**TALIAFERRO,** a N. E. county of Georgia, drained by affluents of the Ogeechee and Little rivers; area, 185 sq. m.; pop. in 1870, 4,796, of whom 2,987 were colored. The surface is hilly and the soil generally fertile. Granite, gneiss, sulphuret of iron, and magnetic ore are found. It is intersected by the Georgia railroad. The chief productions in 1870 were 9,418 bushels of wheat, 78,815 of Indian corn, and 3,024 bales of cotton. There were 543 horses, 2,120 cattle, 1,220 sheep, and 3,714 swine. Capital, Crawfordsville.

**TALIPOT TREE.** See PALM, vol. xiii., p. 20.

**TALLADEGA,** a N. E. county of Alabama, bounded W. by the Coosa river and drained by Chockolocko creek and other streams; area, about 700 sq. m.; pop. in 1870, 18,064, of whom 9,595 were colored. The surface is moderately hilly and the soil fertile. The Selma, Rome, and Dalton railroad traverses it. The chief productions in 1870 were 69,321 bushels of wheat, 284,783 of Indian corn, 42,821 of oats, 14,469 of sweet potatoes, 5,697 bales of cotton, 5,784 lbs. of wool, and 53,167 of butter. There were 922 horses, 1,786 mules and asses, 5,333 cattle, 2,355 sheep, and 6,947 swine; 4 tanneries, 3 currying establishments, and 2 saw mills. Capital, Talladega.

**TALLADEGA,** a city and the capital of Talladega co., Alabama, on the Selma, Rome, and Dalton railroad, 78 m. N. by E. of Montgomery; pop. in 1870, 1,933, of whom 1,013 were colored; in 1875, about 3,000. It is the seat of the state institution for the deaf and dumb and the blind, of a Presbyterian female seminary, and of Talladega college. The college was incorporated in 1869, and is sustained by the American missionary society. It admits both sexes and colors, and has in operation preparatory, theological, and normal courses, and grammar, intermediate, and primary departments. In 1874–'5 it had 13 instructors and 247 students. Talladega has two weekly newspapers and six churches, and trade in cotton, wheat, &c. On its site, Nov. 9, 1813, Gen. Jackson gained a victory over the Creeks.

**TALLAHASSEE,** a city and the capital of Florida, county seat of Leon co., on the Jacksonville, Pensacola, and Mobile railroad, at the junction of a branch to St. Mark's, 155 m. W. of Jacksonville and 21 m. N. of the gulf of Mexico; lat. 30° 25′ N., lon. 84° 18′ W.; pop. in 1870, 2,023, of whom 820 were white and 1,203 colored; in 1875, about 2,500; including suburbs, 4,000. It is beautifully situated on high ground, and is regularly laid out in a plot a mile square, with broad streets and several public squares, shaded with evergreens and oaks. The abundance and variety of flowers and shrubs give it the appearance of a garden. The business portion is of brick. The public buildings are the capitol (commenced in 1826), a large three-story brick edifice, with pillared entrances opening east and west; the court house, a substantial two-story brick structure; and the West Florida seminary, a large two-story brick building, on a hill commanding a view of the entire city. In the vicinity are beautiful springs, the most celebrated of which is Wakulla, an immense limestone basin, 16 m. distant. The surrounding country is fertile. The city contains the car and machine shops of the railroad company, and has the only cotton factory in the state. The seminary has separate male and female departments, and is supported by the proceeds of the "seminary lands" granted to the state by congress. There are several free public schools, two weekly newspapers, and Baptist, Episcopal, Methodist, Presbyterian, and Roman Catholic churches.—The site of Tallahassee was selected as the seat of the territorial government in 1822; it was laid out in 1824, and incorporated as a city in 1827. In 1843 the entire business portion, then of wood, was destroyed by fire.

**TALLAHATCHIE,** a river of Mississippi, the principal tributary of the Yazoo, rising in the N. E. part of the state, and flowing in a circuitous but generally S. W. and S. course 250 m. to its junction with the Yalobusha river to form the Yazoo. It is navigable by steamboats more than 100 m.

**TALLAHATCHIE,** a N. W. county of Mississippi, intersected by the Tallahatchie river; area, about 750 sq. m.; pop. in 1870, 7,852, of whom 4,637 were colored. The surface is level and in many places swampy, and the soil fertile. The Mississippi and Tennessee railroad touches the N. E. corner. The chief productions in 1870 were 203,425 bushels of Indian corn, 13,620 of sweet potatoes, and 6,760 bales of cotton. There were 842 horses, 954 mules and asses, 5,500 cattle, 908 sheep, 7,406 swine, and 6 saw mills. Capital, Charleston.

**TALLAPOOSA,** a river of Georgia and Alabama, which rises in Paulding co., Ga., flows S. W., S., and W. 250 m., and unites with the Coosa, forming the Alabama, about 10 m. N. of Montgomery. Its principal affluent is the Little Tallapoosa. It is navigable for steamboats more than 40 m. above the Coosa.

**TALLAPOOSA,** an E. county of Alabama, intersected by the Tallapoosa river, and drained by its branches; area, 700 sq. m.; pop in 1870, 16,963, of whom 4,190 were colored. The surface is hilly and the soil in some parts fertile. The Savannah and Memphis railroad traverses

it. The chief productions in 1870 were 48,468 bushels of wheat, 267,764 of Indian corn, 33,353 of oats, 26,236 of sweet potatoes, 5,446 bales of cotton, and 10,439 lbs. of wool. There were 1,224 horses, 1,198 mules and asses, 8,251 cattle, 3,538 sheep, 12,799 swine, and 26 flour mills. Capital, Dadeville.

**TALLEYRAND - PÉRIGORD, Charles Maurice,** prince de, a French statesman, born in Paris, Feb. 13, 1754, died there, May 17, 1838. He was the eldest son of the count de Talleyrand-Périgord, and, having been lamed by accident when about a year old, was neglected by his family. In 1766 he was placed by an uncle in the college of Harcourt at Paris, and though he there greatly distinguished himself, a family council in 1769 decided that in consequence of his incurable lameness he should give up his birthright to his younger brother, and become a churchman. He was sent immediately to St. Sulpice, and graduated with much distinction at the Sorbonne in 1774. He was then presented at court, and received *in commendam* the abbey of St. Denis in the diocese of Rheims and several other livings. Despite his notorious licentiousness, he was ordained priest soon afterward, and displayed uncommon business tact and brilliant conversational powers. From 1780 to 1785 he held the post of general agent of the French clergy. He mingled in the financial discussions of the time, became acquainted with Mirabeau, Calonne, and Necker, and was noted for his prudence and skill as a speculator. In 1787 he was one of the assembly of notables, and in 1788 was made bishop of Autun, which gave him a yearly income of 60,000 francs. When the states general were summoned in 1789, he was elected one of the deputies of the clergy, insisted that his colleagues should join at once the representatives of the third estate who had assumed the name of "national assembly," figured conspicuously among Mirabeau's friends, and proved a strong supporter of every liberal measure. It was he who moved the celebration of the great patriotic feast, styled the "federation," on July 14, 1790; and in his capacity of bishop, at the head of 200 priests, wearing the national colors over their white robes, he officiated in that solemnity upon the great altar erected in the midst of the Champ de Mars. In the assembly he reported a plan for the reorganization of public instruction, and advocated the abolition of ecclesiastical tithes, the assumption by the government of the lands belonging to the clergy as national property, and the establishment of a civil constitution for that order; and on this constitution being adopted, he consecrated such priests as consented to take the oath to it. This, added to his many deficiencies as a Catholic bishop and his political course, caused him to be excommunicated; but he was secularized by the pope, on condition that he should wear a lay habit and abstain from all clerical functions. In April, 1791, he attended Mirabeau in his last moments, and was charged by the great orator to deliver in the assembly a speech he had prepared upon testamentary powers and the rights of succession. On the dissolution of the constituent assembly, Sept. 30, 1791, Talleyrand was sent, under Chauvelin, on a fruitless mission to England. After the king's fall he retired to England; but, while a warrant was issued against him in Paris by the committee of public safety, he received peremptory orders from the ministry (January, 1794) to leave England in 24 hours. He then sailed for the United States, where through speculation he accumulated a fortune, and carefully studied American institutions and commerce. Before the adjournment of the convention, on motion of Chénier, acting under Mme. de Staël's influence, his name was erased from the list of emigrants; he returned to Paris, found himself a member of the academy of moral and political sciences, was one of the original members of the constitutional club, and in July, 1797, was called to the ministry of foreign affairs. On Bonaparte's return from Italy, Dec. 5, he welcomed him, introduced him to the directors, delivered a speech in his honor at his great official reception, and promoted his subsequent designs. While the young general sailed for Egypt, the diplomatist was to go to Constantinople to reconcile the sultan to the invasion of one of his provinces; he neglected this mission, and continued in office till July, 1799, when he was forced to resign. When Bonaparte returned from Egypt, he again propitiated the conqueror, procured an interview between him and Sieyès, and prevailed upon Barras to resign, thus greatly contributing to the success of the *coup d'état* of the 18th Brumaire. He was rewarded by his reappointment, in November, 1799, as minister of foreign affairs, which office he held till August, 1807, and aided in the reëstablishment of the peace in Europe, taking part in the successful conclusion of the treaties of Lunéville, 1801, and of Amiens, 1802. On June 29, 1802, Pius VII., at Bonaparte's request, released Talleyrand from excommunication; and yielding to Bonaparte's injunction, he married Mme. Grant, with whom he had lived for several years. The pope's refusal to allow this lady to be presented to him filled Talleyrand with resentment; and he is said to have counselled the partition of the Papal States. He prompted the seizure of the duke d'Enghien, and hastened his execution. After the establishment of the empire he received the office of grand chamberlain, and in 1806 the principality of Benevento in Italy. Having vainly advocated an alliance with England, and feeling the growing coldness of the emperor, he resigned his ministerial office, Aug. 9, 1807, and received the title of vice grand elector, to which a large salary was attached. Thenceforward he was only occasionally consulted by his sovereign, but gave very free expression to his views on great political ques-

tions, and was in consequence deprived of his office of chamberlain in 1809; but this only stimulated his sarcastic criticisms against the imperial policy. As early as 1812 he is said to have foretold the approaching overthrow of Napoleon, and on its occurrence he was looked upon at home and abroad as the most influential statesman of the day and the leader of the new revolution. A last interview between him and the emperor in the beginning of 1814 completed the estrangement between them; and Talleyrand, though still a dignitary of the empire and one of the council of regency, thought of nothing but ruining his master. He secretly sent word to the allied sovereigns to hasten toward Paris; and when that city surrendered, March 30, he offered his hotel to the emperor Alexander. His management secured the appointment by the senate, on April 1, of a provisional government, and its formal declaration on the day following of Napoleon's dethronement. While Marshal Marmont was prevailed upon to sign at Essonne (April 3) a convention that baffled Napoleon's last hopes of resisting, Talleyrand welcomed the count of Artois to the French metropolis, April 12, and remained the head of the new government. On the arrival of Louis XVIII. he was appointed (May 12) minister of foreign affairs, holding in fact the premiership in the cabinet; and on June 4 he was made a peer of France. He negotiated the first treaty of Paris, May 30, 1814; and four months later he was sent as minister plenipotentiary to the congress of Vienna, where he failed in protecting the interests of France as well as he desired. He was surprised there by the sudden return of Napoleon from Elba, and participated in the declaration that "outlawed the enemy of nations." He was excepted from the amnesty granted to those who had previously deserted the emperor, went to Ghent, where he joined the exiled king Louis XVIII., accompanied him to France when he returned there after the battle of Waterloo, and resumed, July 8, 1815, the premiership in the cabinet and the ministry of foreign affairs; but being disgusted by the hard terms imposed upon France by the allied powers and by the reactionary tendencies of the new chamber of deputies, he resigned his office at the end of a few weeks. According to another account, having become obnoxious to the emperor Alexander, he was dismissed; but through the duke of Richelieu's entreaties he received the title of grand chamberlain of France, with a salary of 40,000 francs. He still visited the Tuileries, but was coldly received; he retained his seat in the chamber of peers, and delivered there several opposition speeches; but his influence was greatest in social intercourse, his saloon being the gathering place of politicians of every shade of opinion. After the revolution of July, 1830, he was appointed ambassador to England with a princely salary, and negotiated a treaty, April 22, 1834, by which France, England, Spain, and Portugal united for the pacification and settlement of the two peninsular kingdoms. He resigned his office, Jan. 7, 1835, and retired to private life. The most remarkable of his essays is his *Mémoire sur les relations commerciales des États-Unis vers* 1797. He left personal memoirs, which according to his will were not to be published till 30 years after his death. In 1868 Napoleon III. obtained from the heirs a further postponement of 22 years; and in 1872, it having been announced that the memoirs were about to be published, the duke de Montmorency, custodian of the manuscript, refused to violate the pledge given to the late emperor. On the day before his death Talleyrand wrote a letter to the pope enclosing a "retraction" written two months before. The "retraction" deplores his acts which had afflicted the church; and the letter says that his memoirs will explain to posterity the writer's conduct during the revolution.

**TALLIEN, Jean Lambert,** a French revolutionist, born in Paris in 1769, died there in November, 1820. He was the son of the house steward of the marquis de Bercy, who gave him the means of a classical education. In 1791 he started a transient newspaper, *L'Ami du Citoyen*, and became a member of the Jacobin club, and in 1792 clerk of the commune of Paris and deputy to the convention from Seine-et-Oise. He took his seat among the *montagnards*, voted for the death of Louis XVI., and was one of the bitterest opponents of the Girondists. He was sent on a mission to Bordeaux in 1793, and became acquainted with Mme. de Fontenay, whom he married. (See Chimay.) At her instigation he denounced Robespierre and procured his execution, which made him the leader of the Thermidorians. Through his influence Fouquier-Tinville, Carrier, and Lebon were doomed to punishment; and through his energy the revolutionary attempt of the 1st Prairial was baffled. As commissary of the convention with the army of the west in 1795, he ordered all the royalist prisoners made by Hoche on the Quiberon peninsula to be shot. On the 13th Vendémiaire he was among the defenders of the convention against the rebellious sections of Paris. After the establishment of the directorial government he was a member of the council of 500, and shared in the republican *coup d'état* of the 18th Fructidor. In 1798 he accompanied Bonaparte to Egypt as one of the committee of scientific men, and held there a high administrative office. While returning to France he was taken prisoner by the English, and welcomed to London by the whig party. In 1805 he was appointed consul to Alicante; but sickness obliged him to return to Paris, where he received a paltry pension from Napoleon, which he lost in 1811. Mme. Tallien, from whom he was divorced in 1802, had borne him four children.

**TALLOW**, the solid fat of various terrestrial animals, chiefly quadrupeds, which has been separated from the membranous cellular tissue by melting. The ruminants, particularly oxen and sheep, furnish the tallow of commerce. Russia, South America, and Australia furnish the largest proportion. That is esteemed best which is procured from animals that have fed upon dry fodder; hence that of Russia, where animals feed for eight months upon dried grass, is especially valued. Texas and particularly southern California formerly furnished large quantities to commerce. Formerly tallow that had been simply "tried out" or "rendered" was extensively used for candles; very little is now so used, but instead of it the stearine which has been separated from the other constituents is made into candles, which are of more uniform quality and higher melting point. (See Stearic Acid.) Tallow is also largely consumed by soap manufacturers (see Soap), and in the dressing of leather. Tallow consists of several compound acid radicals united with the basic radical of glycerine. Of these, stearine is found in largest quantity, with more or less of palmitine and oleine, depending upon the kind of tallow. In the process of soap making the tallow is decomposed, the potash or soda combining with the stearine, &c., and setting glycerine free.—Vegetable tallow is obtained in China in great quantities from the solid sebaceous covering of the seeds of *Stillingia sebifera*, a tree that is extensively cultivated in that country. (See Tallow Tree.) The tallow, which is brittle, white, opaque, and tasteless, is preferred to animal tallow for making candles. It is regarded as nearly pure stearine. In the United States, the wax-like covering of the berries of the *myrica cerifera* is in some localities used for the same purposes as ordinary tallow, under the name of bayberry tallow. It is hard, of olive-green color, and has a fragrant spicy odor. It is also used to a limited extent in pharmaceutical preparations.

**TALLOW TREE** (*Stillingia sebifera*), a Chinese tree, belonging to the spurge family (*euphorbiaceæ*), growing from 20 to 40 ft., with long and flexible branches, and long-petioled leaves, much resembling those of the poplars, save that they are entire; the flowers are in dense terminal spikes, the upper part of which consists of sterile flowers, with a few fertile ones at the base; the fruit a small three-lobed capsule with one seed in each cell; the seeds are covered with a white tallow-like substance, which gives the tree its common name, and which the Chinese use for candles. This tree is abundantly naturalized in Georgia and South Carolina near the coast, and in Florida on the St. John's. The time and manner of its introduction do not seem to be known; Michaux in 1803 speaks of it as being in cultivation in Charleston and Savannah, and as also growing spontaneously at that time; and Elliott (1824) speaks of the abundance of the fruit, of which no use is made, though it contains much oil. The seeds produce two oily substances: the tallow-like coating which envelops them, and an oil within the kernel itself. To obtain the first, the capsules are cracked without bruising the seeds, the shells separated, and the seeds treated with boiling water and the tallow

Tallow Tree (Stillingia sebifera).

skimmed off; after this, the seeds are crushed and pressed for their oil. The tallow when fresh is creamy white, but it becomes brown on long exposure; the Chinese convert it into candles, which receive a final dip in a mixture of the same substance with some insect wax, which gives them a hard surface and preserves their form in hot weather; the oil is used for lamps; the refuse of the process is used for fuel and for manure. The wood is hard, and is used by the Chinese to make blocks for printing.—Another species, *S. sylvatica*, popularly known as queen's delight, is an herb, 2 or 3 ft. high, with alternate, nearly sessile, oblong-lanceolate, serrate leaves, and a dense terminal yellowish spike of male flowers with a few fertile ones at the base; it is found in light dry soils from Virginia to Florida. The root in large doses is emetic and cathartic; in small doses it is regarded by some southern physicians as influencing the secretions, and it is useful in syphilis and skin diseases.

**TALMA, François Joseph**, a French actor, born in Paris, Jan. 15, 1763, died there, Oct. 19, 1826. He received a collegiate education, and in 1787 appeared at the Théâtre Français in the part of Séïde in Voltaire's *Mahomet*. He early turned his attention to the substitution of contemporary historical dresses for the fancy costumes then worn, a reform which had been previously and unsuccessfully attempted by Lekain, and which Talma finally effected. His first original creation was the principal part in Joseph Chénier's *Charles IX*. Besides the parts he performed in Lafosse's *Manlius*, Racine's *Iphigénie* and *Britannicus*, and Voltaire's

*Œdipe*, he won great applause in Chénier's *Henri VIII.*, and above all in Ducis's *Hamlet*, *Othello*, and *Abufar ;* and under the empire he frequently played before royal audiences. During the restoration some of his most popular performances were political manifestations in disguise; especially in Jouy's *Sylla*, in which his striking resemblance to Napoleon made a great sensation. Since 1796 he had devoted his undivided attention to tragedy; but in 1823 he appeared as Damville in Casimir Delavigne's comedy *L'école des vieillards*, in which he proved a worthy associate of Mlle. Mars. He represented and may be said to have created more than 70 characters. His last and perhaps most perfect creation was the part of Charles VI. in Delavigne's tragedy, and in which he made his last public appearance in June, 1826. In 1855 a statue by David d'Angers, representing Talma in his great part of Sylla, was placed in the Tuileries garden. He left an interesting pamphlet entitled *Réflexions sur Lekain et sur l'art théatral* (8vo, 1815; reprinted in 1856 and 1865). His memoirs by Moreau, by Tissot, and by Duval appeared in 1826; by Laregier, by Lemercier, and by Regnault-Warin, in 1827; and his autobiography, edited by Alexandre Dumas, in 1849–'50 (4 vols. 8vo).—His wife, originally Mlle. Vanhove (born at the Hague, Sept. 10, 1771, died in Paris, April 11, 1860), was one of the most remarkable actresses of her day, but retired from the stage in 1811, nine years after her marriage.

**TALMAGE, Thomas De Witt,** an American clergyman, born in Boundbrook, N. J., Jan. 7, 1832. He graduated at the New York university in 1853, and at the New Brunswick (N. J.) theological seminary in 1856, and was ordained pastor of the Reformed Dutch church in Belleville, N. J. He was pastor of the Reformed Dutch church in Syracuse, N. Y., from 1859 to 1862, when he was called to the second Reformed church in Philadelphia; and in 1869 he became pastor of the Central Presbyterian church in Brooklyn, N. Y., in which office he still continues (1876). In 1870 his congregation erected a new church, semicircular, of wood and iron, and capable of seating 3,400 persons. This building, known as the "Brooklyn Tabernacle," was enlarged in 1871 so as to seat 500 more, but was destroyed by fire Dec. 22, 1872. On Feb. 22, 1874, a new "Tabernacle" was dedicated, built in Gothic style, of brick, but retaining the semicircular arrangement, and seating 5,000 persons. It is the largest Protestant church in America. Since the erection of the former tabernacle the church, at Mr. Talmage's instance, has been free, being maintained wholly by voluntary offerings, with no pew rents. In 1872 he organized in the building formerly occupied by the church a lay college for religious training. It is open to persons of all denominations, and gives instruction in philosophy, logic, and general literature, and in natural and systematic theology, sacred history, the evidences of Christianity, the interpretation of Scripture, and sacred rhetoric. Mr. Talmage is a very popular lecturer, but has latterly seldom appeared in that capacity. His sermons are delivered extempore, but are reported, and published in several religious journals in the United States and Great Britain. He has edited a religious newspaper, "The Christian at Work," since 1874, and has published four volumes of "Sermons" (New York, 1872–'5); "The Almond Tree in Blossom" (Philadelphia, 1870); "Crumbs Swept Up" (1870); "Abominations of Modern Society" (New York, 1872); "Around the Tea Table" (Philadelphia, 1874); "Old Wells Dug Out" (New York, 1874); "Sports that Kill" (1875); and "Every-Day Religion" (1875).

**TALMUD** (late Heb., study), the collective name of the Mishnah and Gemara, containing the oral law and other traditions of the Jews. (See MISHNAH, and HEBREWS, vol. viii., pp. 593–'5.) In a limited sense the term is used of the Gemara alone. The Mishnah constitutes the earlier text of the Talmud, which the Gemara elucidates, not so much in the manner of a running commentary as by furnishing additional textual paragraphs with explanatory remarks, given in the name of renowned scholars. Authority is placed against authority, and discussions in the form of dialogues are frequent. The arguments show keenness, but are often fanciful in the extreme. There are two Gemaras (or Talmuds), the Palestinian (*Yerushalmi*, of Jerusalem) and the Babylonian (*Babli*). The former contains comments on 39, and the latter on 36 treatises of the Mishnah. The Babylonian, which is later, is the principal authority. The Mishnah is in the Hebrew dialect used after the exile; the Gemara in an Aramaic idiom, very corrupt, especially in that of Jerusalem. The rabbis cited in the Mishnah and the Gemara are the representatives of Jewish religious learning during about six centuries, beginning shortly before the time of the Maccabees. The chief commentator is Rabbi Solomon ben Isaac, known under the abbreviation Rashi. The best compendium of Talmudical decisions is the *Mishneh torah* of Maimonides. The editions of the Talmud, mostly in 12 folio volumes, including the most important commentaries and notes, are very numerous. They are so arranged that the Mishnah and Gemara, in square Hebrew characters without vowel points, occupy the centre of the page, and the chief commentaries and notes (Rashi's, *Tosaphoth*, &c.), in a mediæval style of writing, the margins all around. Other commentaries are generally added at the end of each treatise. One of the fullest is the Warsaw edition of the Talmud of Babylon (1859 *et seq.*). An important essay on the Talmud was published by Emanuel Deutsch in the "Quarterly Review" (1869; reprinted in his "Literary Remains," New York, 1873), and another by M. Grünbaum some months later in the "North

American Review." The best Talmudical lexicon is J. Levy's *Wörterbuch über die Talmudim und Midraschim* (Leipsic, 1875 *et seq.*), based, like its predecessors, on Nathan ben Jehiel's *'Arukh*, composed about 1100.

**TAMA,** an E. central county of Iowa, intersected by the Iowa river; area, 720 sq. m.; pop. in 1870, 16,131. The surface is undulating and the soil highly fertile and well timbered. There are rich valleys along the streams, and good water power. It is intersected by the Chicago and Northwestern railroad. The chief productions in 1870 were 1,054,167 bushels of wheat, 1,103,371 of Indian corn, 282,591 of oats, 23,588 of barley, 88,616 of potatoes, 17,080 lbs. of wool, 407,567 of butter, and 25,854 tons of hay. There were 7,959 horses, 6,073 milch cows, 9,218 other cattle, 4,547 sheep, and 17,646 swine; 11 manufactories of carriages and wagons, 3 of furniture, 3 of lime, 5 of saddlery and harness, 8 flour mills, and 3 saw mills. Capital, Toledo.

**TAMANDUA.** See Ant-Eater.

**TAMAQUA,** a borough of Schuylkill co., Pennsylvania, on the Little Schuylkill river and on branches of the Philadelphia and Reading railroad and the Central railroad of New Jersey, 16 m. E. N. E. of Pottsville and 60 m. N. E. of Harrisburg; pop. in 1870, 5,960; in 1875, about 7,000. It is in a rich coal and iron region, and has good water power. It contains three machine shops and founderies (one of them the largest in the state), stove works, a boot and shoe factory, a rolling mill, two saw mills and sash factories, a spike factory, a brick kiln, a powder mill, a tannery, a lime kiln, two breweries, seven or eight bottling establishments, a gun factory, two screen factories, and two saddle and harness factories, besides shops of the Philadelphia and Reading railroad company. It has a fire department, a national bank, a banking and trust company, three brick school houses, a daily and a weekly newspaper, and ten churches.

**TAMARACK.** See Larch.

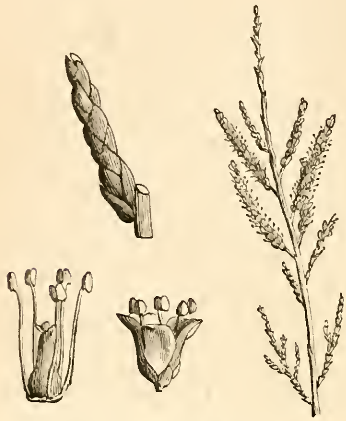
**TAMARIND,** the fruit of a leguminous tree, *tamarindus Indica*, the common and botanical name being derived from the Arabs, who, having learned of the fruit from the Hindoos, called it *tamare-hindi*, the Indian date. The tree is indigenous to various parts of Africa, and probably also to India, and it grows wild in several of the East Indian islands; it was early introduced into the West Indies, and is completely naturalized there, and also in portions of Brazil and Mexico. There is only one species of the genus. It is a large handsome tree, 60 to 80 ft. high; its compound leaves, of 10 to 20 pairs of small oblong leaflets, form a dense foliage; the flowers, white when they first open, but soon turning yellow, have purple and brown stamens, are borne in racemes, and are fragrant; the fruit is an indehiscent legume or pod, 3 to 6 in. long, straight or curved, thick, and with a hard, brittle exterior shell; the seeds, from 4 to 12, are each surrounded by a tough papery membrane, outside of which, and between it and the shell, is a firm, juicy, very acid pulp, traversed by strong woody fibres, which start from the fruit stalk and run through, throwing off branches, to the opposite end (apex) of the pod. The ripeness of the pods is known by the brittleness of the outer shell; they are picked, and in the West Indies deprived of the shell and packed in a cask, and boiling sirup is poured over them until the vessel is full; when cool the package is headed up and is ready for market. A better kind, rarely found on sale, is prepared by packing the shelled fruit in stone jars, with alternate layers of sugar. In the East Indies the fruit is usually preserved without sugar; the shell is removed and the pulp and seed are kneaded into a mass, and in this form tamarinds are chiefly used on the continent of Europe. The pulp has a brisk acid taste, modified more or less by the amount of sugar used; it contains tartaric, citric, and other acids, and some principle not well ascertained which gives it a laxative property. Tamarinds are used, especially in tropical countries, to prepare a refreshing drink, by pouring boiling water

Tamarind (Tamarindus Indica).

over the fruit; this drink is also used as a laxative and refrigerant in fevers. By boiling the preserved fruit with a small quantity of water, and sifting, the pulp is obtained pure; it is used as an article of diet, and it enters into the composition of a popular laxative, the compound confection of senna. The wood is useful for timber, and makes a fine charcoal. The shell of the seeds is astringent and contains tannin; their kernels are used as food in India in times of scarcity.

**TAMARISK,** the name of ornamental shrubs of the genus *tamarix* (the ancient name, supposed to be from the river Tamaris), of a small family (*tamariscineæ*) closely related to the pink family. The genus belongs to the old world, and the more than 50 described species are reducible to about 20, all shrubs or small trees, with minute scale-like or awl-shaped, alternate leaves, which are appressed, and small purplish flowers in terminal spikes or racemes; the parts of the flower are in fours or fives; it has a one-celled ovary, ripening into a pod

with many seeds, each of which has a small tuft of hairs. The common tamarisk (*T. Gallica*) is abundant on the Mediterranean and Atlantic coasts of Europe, and, though spontaneous in England, is thought to have been introduced there; from its slender graceful



Common Tamarisk (Tamarix Gallica).

habit, and the abundant though not showy flowers, this is deserving of a place among shrubbery; in the northern states it is often killed to the ground in severe winters. *T. Africana* and others are offered in the catalogues, but there is much confusion as to names. *T. mannifera* of the East (regarded by some botanists as a variety of *T. Gallica*) is supposed by some to be the plant the manna from which fed the Hebrews. (See MANNA.) Tamarisk manna is produced in small drops from the *T. Gallica* in Arabia, the branches having been punctured by an insect. Tamarisk galls are found upon *T. orientalis*, in N. W. India, and are used in India instead of oak galls.

**TAMATAVE,** a town and the principal port of Madagascar, on the E. coast, in lat. 18° 10′ S., lon. 49° 28′ E.; pop. about 7,500. It is built on a point about 350 yards wide, with low sand hills behind it. Nearly all the buildings, excepting a few belonging to foreign residents, are in the native style, with high roofs thatched with rushes. The town has a large trade with the interior, and is fast increasing in commercial importance. The total value of imports in 1873 was $487,255; of exports, $360,930. The principal imports are sheetings, calico, rum, brandy, shoes, and salt; exports, beef, hides, and India rubber. The duties are 10 per cent. in kind on imports, and 10 per cent. in money on exports.

**TAMAULIPAS** (formerly Nuevo Santander), an E. state of Mexico, bounded N. by Texas, E. by the gulf of Mexico, S. by Vera Cruz, and W. by San Luis Potosí and Nuevo Leon; area, 28,659 sq. m.; pop. in 1871, 108,778. The coast is low and sandy, and several lagoons extend along the shore, the largest being the laguna Madre, more than 100 m. long, and in some places 20 m. wide. The Rio Grande del Norte forms the northern boundary line; other rivers are the Fernando or Tigre, Borbon, Santander, and Tampico; the mouths of all are so much encumbered with bars that they are almost useless for navigation. In the northern part of the state the flat country extends inland for some distance, and the surface then rises into elevated plains; but in the south it is diversified by numerous mountains and fine valleys. During the hot season the climate on the coast is unhealthful, but in the elevated parts of the interior it is temperate and agreeable. There are rich silver and copper mines, but they are little worked. The forests abound in valuable timber. Much of the soil is very fertile, and the grains, vegetables, and fruits of the temperate and torrid zones are easily grown; but little attention is paid to agriculture. Vast numbers of cattle, and to a less extent horses, mules, goats, and sheep, are reared. The chief towns are Ciudad Victoria, the capital, Matamoros, and Tampico.

**TAMBERLIK, Enrico,** an Italian singer, born in Rome in 1820. He made his début at the Teatro del Fondo in Naples in 1841, and subsequently sang in Spain, South America, England, and St. Petersburg, in which city he appeared for 18 consecutive seasons. He visited the United States in 1875, but without success, his voice being impaired.

**TAMBOURINE,** an instrument of the drum species, consisting of a wooden or metal hoop, over which parchment is distended, and which is hung with a set of bells. It is held in either hand and beaten with the knuckles of the other. Certain peculiar effects of sound are produced by rubbing the parchment briskly with the thumb. The tambourine is one of the most ancient instruments known, and, from the graceful use which can be made of it, has always been a favorite with dancers.

**TAMBOV.** I. A S. E. government of European Russia, bordering on Vladimir, Nizhegorod, Penza, Saratov, Voronezh, Orel, Tula, and Riazan; area, 25,683 sq. m.; pop. in 1870, 2,150,971. It is level, and partly traversed by steppes in the south. The chief rivers are the Tzna, Moksha, and Vorona, the banks of which are swampy and covered with forests. Grain, hemp, flax, and poppies are raised, especially in the southern part. The other products include timber, peat, iron, saltpetre, and sulphur; and there are many mineral springs. The government is celebrated for its horse markets and studs. II. A city, capital of the government, 260 m. S. E. of Moscow; pop. in 1867, 28,617. It is the seat of a bishop, and has many churches, schools, and charitable institutions, and manufactories of tallow, woollens, sail cloth, &c. The annual markets are celebrated. Gardens and fine streets make it one of the pleasantest of provincial cities.

**TAMBURINI, Antonio,** an Italian singer, born in Faenza, March 28, 1800. After several

years' practice in the theatre and churches of his native city, he made his public début at Bologna in 1818, and soon rose into great celebrity in Italy. In 1832 he first appeared in London and Paris, and thenceforth visited them annually until his retirement in 1854, when he settled at Sèvres, France. With Grisi, Rubini, and Lablache, he was one of the original performers in Bellini's *Puritani*, and for several seasons continued a member of that remarkable quartet. His voice, a baritone of great power and sweetness, was shown to the best effect in the operas of Rossini, Bellini, and Donizetti, and he was also an excellent actor both in serious and buffo opera. His finest parts were Figaro and Don Giovanni.

**TAMBURINI, Pietro,** an Italian theologian, born in Brescia in 1737, died in Pavia in March, 1827. In 1772, while professor in the seminary of Brescia, he was appointed by Pope Clement XIV. prefect of studies in the Irish college of San Isidoro at Rome. In 1778 he was appointed by the empress Maria Theresa professor of theology at Pavia and director of studies in the Germano-Hungarian college in that city. In 1795 he resigned his professorship, but in 1797 the French authorities in Lombardy compelled him to fill the chair of ethics and international law in the university. This chair was suppressed in 1798, but restored in 1801, and filled by him till 1818, when he was appointed dean of the faculty of law. He published *Idea della Santa Sede* (Pavia, 1784), in which he opposed the doctrine of papal official infallibility, while maintaining the jurisdictional supremacy of the Roman see; *Introduzione allo studio della filosofia* (Milan, 1797); *Lezioni di filosofia morale, e di naturale e sociale diritto* (4 vols., Pavia, 1806–'12); *Elementa Juris Naturæ* (Milan, 1815); and *Cenni sulla perfettibilità dell' umana famiglia* (Milan, 1823).

**TAMERLANE.** See Timour.

**TAMILS, or Tamuls.** See India, Races and Languages of, vol. ix., p. 215.

**TAMPICO, or Santa Aña de Tamaulipas,** a seaport town of Mexico, in the state of Tamaulipas, on the river Pánuco, 5 m. from the gulf of Mexico, and 235 m. N. N. W. of Vera Cruz; pop. about 5,500. It is on rising ground, with wide streets crossing at right angles. The houses are mostly of stone, and there are two churches, a custom house, two hospitals, a prison, and some monuments. The harbor is not very safe, and has a dangerous bar. The commerce is principally with New York, New Orleans, and Liverpool, and to the latter port there is a regular line of steamers. For the year ending Sept. 30, 1874, the value of imports was $715,821; of exports, $1,836,472, including $1,264,015 specie.

**TANAGER,** a name given to the *tanagrinæ*, a very large division of the finch family, peculiar to America, and almost entirely confined to the southern portion of the continent, which contains nearly 200 of the more than 220 species described by Sclater. The bill has the upper mandible notched, and is usually triangular at the base and arched; the toes have strong claws, and the hind toe is long and strong. They are small and brilliant birds, the prevailing colors being orange, scarlet, and black; many have a pleasing song, and a few are remarkable for their musical powers; their flight is rapid, movements active, and habits arboreal; most unite in flocks, often in the neighborhood of human habitations, but a few are solitary; the food consists of insects, fruits, and seeds. Of the 20 genera, only a few of the common ones can be here noticed.—In the genus *pyranga* (Vieill.) the wings are long and pointed, the second quill nearly as long as the third, which is longest; tail moderate and nearly even. One of the most richly colored of North American birds is the scarlet tanager (*P. rubra*, Vieill.), about 7¼ in. long and 11¾ in. in alar extent; the male in the breeding season is of a general bright carmine color, with the wings and notched tail velvety black; the female is dull yellowish green, which is also the color of the young and the other sex in autumn and winter.

Scarlet Tanager (Pyranga rubra).

It enters the United States from Mexico early in April, arriving in New Jersey about the middle of May; it goes as far north inland as Lake Huron, and has been found breeding in New Brunswick and Nova Scotia; it is very sensitive to cold; its migrations are performed at night; its notes are lively, but not musical according to Wilson, resembling the syllables "chip, churr." The change from the winter to the summer plumage takes place very rapidly; it is shy and unsociable, preferring the deep recesses of forests, and rarely approaching human habitations in crowded villages; the food consists of fruits and insects, especially wasps and bees. As in the subfamily generally, the nest is thin and coarsely made; the eggs are three to five, dull greenish blue with brown and purple specks, and are seven eighths by five eighths of an inch in size. This species is found from the eastern states to Missouri. The Mississippi tanager or summer red bird (*P. æstiva*, Vieill.) is 7¼ in. long and 11 in. in alar extent; the color is light red, brightest on the head, the back dusky, and the quills and shafts of tail feathers brown; bill light horn

color, and the gape, as in others of the genus, well provided with bristles bending downward; the females olive above and reddish yellow below, as are the young males; the color is lighter and more rosy than in the scarlet tanager, and the bill is much larger. It is found in the S. Atlantic and gulf states and Guatemala, is so sensitive to cold that it rarely goes further north than Massachusetts, and is not seen in the southern states after the middle of September; it is of solitary habits, preferring growths of stunted hickories and oaks. The song is like the syllables "chicky, chucky, chuck," and is chiefly at night; the food consists of insects, especially large beetles, taken on the wing; the nest is rudely made and insecurely fastened to its supporting branch; the eggs are four or five, light blue, and are incubated for 12 days by both sexes. In the genus *tanagra* (Linn.) the bill is short, elevated at base, rather triangular; the wings moderate, with the third and fourth quills longest. There are many species, all South American, living in troops; the nest is carelessly made. The bishop tanager (*T. episcopus*, Linn.) is purplish violet, with the small wing coverts bluish white, the middle shaded with violet, the larger ashy, and the wings and tail blackish bordered with blue.—The genus *calliste* (Boie) comprises about 30 species of the most beautifully variegated of tropical birds, all inhabitants of the dense South American forests. The best known species is the festive tanager (*C. festiva*, Boie), which has the throat and crown blue, forehead and upper back black, collar scarlet, rest of plumage parrot green. The celebrated *organista*, remarkable for the sweetness and great compass of its voice, belongs to the genus *euphonia*.

**TANAIS.** See DON.

**TANANARIVO**, or **Antananarivo**, a city of Madagascar, capital of the province of Imerne in the territory of Ankova, and the residence of the so-called sovereign (now queen) of Madagascar, near the middle of the island, in lat. 18° 56′ S., lon. 47° 28′ E.; pop. about 75,000. It is on a long irregular hill in the midst of a highly cultivated valley, 18 m. long by 10 m. wide, and 7,000 ft. above the sea. The houses of the better classes are substantially constructed of wood, with high bamboo roofs thatched with rushes; those of the poorer classes are of split bamboo covered with mats. The palace, on the summit of the hill, is rectangular, about 60 ft. high, with a tall roof pierced with three rows of windows, and with double verandas. A smaller palace near by is the residence of the prince royal, and the houses of the chief nobles and military officers are in the immediate vicinity. N. of the palace is a natural amphitheatre, capable of holding 100,000 persons, where large public assemblies are held. Courts are held in the open air W. of the palace, and a little beyond is a precipice 300 ft. high, down which those convicted of witchcraft and sorcery are thrown. Through the efforts of the missionaries a marked improvement has taken place of late years in the habits and manner of life of the people, who have adopted many European customs. Schools and chapels have been established, printing offices opened, and many thousand Bibles and other books printed.

**TANCRED**, an Italian crusader, born in 1078, died in Antioch in 1112. He was a son of the marquis Odo or Ottobonus and of Emma, a daughter of Tancred de Hauteville and sister of Robert Guiscard, duke of Apulia. He took the cross under his cousin Bohemond, son of Robert Guiscard, made over his heritage to his younger brother, and embarked in 1096 from Taranto. In the plains of Chalcedon his troops joined those of Godfrey of Bouillon, with whom he formed an intimate friendship. At the siege of Nicæa in 1097 he distinguished himself, at the battle of Dorylæum saved the army of the cross from destruction, and after the taking of Nicæa led the advanced guard through Asia Minor. He took possession of Tarsus and Malmistra, to both of which Baldwin laid claim, giving rise to a bitter quarrel; but they were afterward reconciled. He achieved great distinction during the siege of Antioch; and at the storming of Jerusalem he was one of the first to mount the walls. In the carnage and rapine which followed, he almost alone of the Christian knights manifested compassion, and at the risk of his own life saved thousands of the captured. When the sultan of Egypt marched toward Jerusalem, Tancred defeated his advanced guard, and shared in the subsequent victory at Ascalon, Aug. 12, 1099. He afterward took Tiberias, beleaguered Jaffa, and was made prince of Tiberias or Galilee. Bohemond, now prince of Antioch, being taken prisoner by the Saracens, Tancred marched to his relief, and administered his government during his detention; and when Bohemond after his release went to Europe to arm the West against the Byzantine empire, he left the defence of Antioch to Tancred. During his absence his principality was attacked on all sides, but was heroically defended by Tancred, who reduced Artesia, besieged Tripoli in 1109, and subsequently withstood in Antioch a severe siege from the Saracens. Bohemond died at Salerno, and the host he had collected was scattered. Tancred now resumed the offensive, defeated the Saracens, and forced the sultan to evacuate Syria. His exploits have been celebrated, partly in prose, partly in verse, by Raoul de Caen, in *Les gestes de Tancrède;* and he is one of the principal characters of Tasso's "Jerusalem Delivered."

**TANEY**, a S. W. county of Missouri, bordering on Arkansas, and drained by White river and its affluents; area, about 700 sq. m.; pop. in 1870, 4,407, of whom 10 were colored. The surface is hilly, and the soil fertile. The chief productions in 1870 were 6,375 bushels of wheat, 135,577 of Indian corn, 11,075 of oats, and 48,250 lbs. of butter. There were 1,163

horses, 1,025 milch cows, 1,594 other cattle, 3,189 sheep, and 9,500 swine. Capital, Forsyth.

**TANEY, Roger Brooke,** an American jurist, born in Calvert co., Md., March 17, 1777, died in Washington, D. C., Oct. 12, 1864. He belonged to a Roman Catholic family, graduated at Dickinson college, Pa., in 1795, was admitted to the bar in 1799, commenced practice in his native county, and was elected a delegate to the general assembly as a federalist. In 1801 he removed to Frederick, and in 1816 was elected to the state senate. In 1822 he removed to Baltimore, where he continued to reside until his death. In 1824 he identified himself with the supporters of Gen. Jackson, but was nevertheless made attorney general of the state by the federal governor in 1827. In 1831 he was appointed by President Jackson attorney general of the United States. He supported the president in his controversy with the United States bank, and in September, 1833, was appointed secretary of the treasury on the dismissal of Mr. Duane from that office; and he immediately issued orders for the removal of the government deposits from the United States bank to the local banks selected by him as agents of the government. When his nomination was communicated to the senate, that body rejected it by a vote of 28 to 18. In 1835 he was nominated to fill a vacancy on the bench of the supreme court, but was not confirmed by the senate. When Chief Justice Marshall died, and the president nominated Mr. Taney as his successor, the senate, now having an administration majority, confirmed the nomination, and he took his seat upon the bench in January, 1837. In the decision of the questions which came before him as a judge he displayed great ability; and though his views of constitutional law were less in the direction of centralization than those of his predecessor, he did not fail to sustain to the fullest extent the powers which he believed were justly claimed for the federal government. A striking illustration of this is the case of Ableman *v.* Booth, 21 Howard, 506 (1859), in which he denied the right of the state courts to inquire into the validity of imprisonment by or under a claim of federal authority, and asserted exclusive jurisdiction for that purpose in the federal courts; a decision opposed to the general practice that had before prevailed, but which has recently been reaffirmed by the court. The most noted of his decisions was that in Dred Scott *v.* Sandford, 19 Howard, 393. In that case Scott, who was held as a slave in Missouri, brought suit to recover his freedom, suing in the federal court on the ground of being a citizen of a different state from the defendant, and claiming his freedom because of having been taken by his master into territory made free by the act of congress commonly called the Missouri compromise. The case, having been decided in the circuit court, was removed to the supreme court. The decision (1857) declared that Scott was not entitled to bring suit in the federal court, because he was not a citizen; the chief justice in an elaborate opinion declaring that for more than a century previous to the adoption of the declaration of independence negroes, whether slave or free, had been regarded "as beings of an inferior order, and altogether unfit to associate with the white race, either in social or political relations; and so far inferior that they had no rights which the white man was bound to respect." Having reached this conclusion, which of itself put an end to the case, the court went further, and considered the main question involved, namely, whether it was competent for congress to exclude slavery from the territories of the Union; and the majority, Justices McLean and Curtis dissenting, denied the power. The party dissatisfied with this conclusion made it the occasion for a severe arraignment of the court, not only because of the views held as to the right to legislate against slavery, but because those views were expressed in a case not calling for them, inasmuch as the court had already decided that it had no jurisdiction. The decision, in its denial of the right of citizenship to negroes, was disregarded by the executive department after Mr. Lincoln became president, and by the judicial also when Mr. Chase became chief justice and admitted colored persons as practitioners in the federal courts. In May, 1861, Chief Justice Taney was applied to for a writ of *habeas corpus* on behalf of John Merryman of Baltimore, who had been arrested under the orders of a federal general, and promptly issued the writ. The officer to whom it was addressed declined to obey, on the ground that Merryman had been arrested on a charge of treason, and that the officer had been duly empowered by the president to suspend the writ of *habeas corpus*. Upon this the chief justice ordered an attachment to issue, but as it was impossible to serve this, he wrote out his opinion denying to the president the power to suspend the writ of *habeas corpus*, and insisting that it could only be done by legislative authority. To this opinion no attention was paid at the time, but congress soon passed the necessary law to meet the objection. A memoir of his life, prepared at his request by his friend Prof. Samuel Tyler (Baltimore, 1872), includes his autobiography, which only comes down to 1801. A bronze statue of him by Rinehart, ordered by the state of Maryland, was unveiled in Annapolis, Dec. 10, 1872.

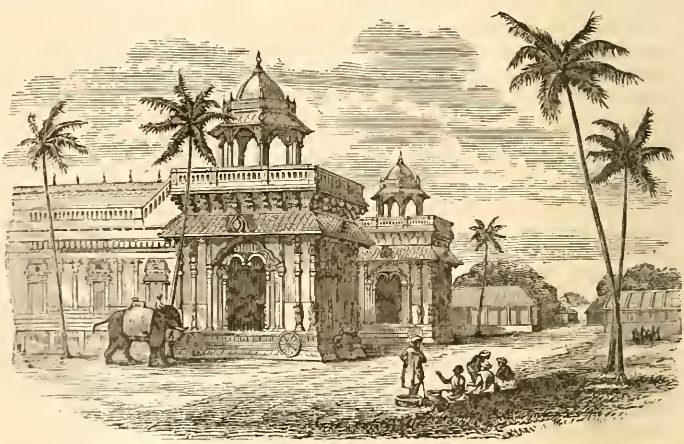
**TANGANYIKA** (the meeting place of waters), a lake in central Africa, discovered by Burton and Speke on Feb. 13, 1858. It occupies a long depression in a region of considerable elevation, S. of the Victoria and Albert lakes and N. W. of Lake Nyassa. It is included between lat. 3° and 9° S., and lon. 29° and 32° 30′ E., and extends about 400 m. in a N. W. and S. E. direction, its width varying from 10 to 60 m. Its height above the level of the sea,

according to the latest observations (made by Lieut. L. V. Cameron, R. N., 1874), is 2,711·2 ft. The water is deep and pure, though peculiar in taste. The northern portion of the lake, which was thoroughly explored by Livingstone, lies between the 29th and 30th meridians, and narrows as it trends northward, being largely hemmed in by mountains on or near the coast. Nearest the W. shore, just S. of the 4th parallel, is the large island of Mozima, 40 m. long. At its N. extremity the lake receives the waters of the Rusizi. S. of lat. 6° the lake is wholly E. of the 30th meridian. The E. coast is hilly. The wide bay which forms the S. extremity of Tanganyika is the Lake Liemba of Livingstone. Between lat. 6° and 7° the W. coast rises into mountains 2,500 ft. high, wooded to their summits. On both sides innumerable small streams and many considerable rivers flow into the lake. The river Lukuga, discovered by Lieut. Cameron on the W. coast in May, 1874, which is 300 to 500 yards wide and from three to five fathoms deep, leaves the lake, near lat. 6°, with a current of 1·2 knot an hour. This explorer traced the river four or five miles, until his boats were stopped by the density of the aquatic vegetation.—The hydrographic relations of Lake Tanganyika have been the subject of much controversy. As to its asserted connection with the Nile system, see NILE. According to native information, the Lukuga flows into Livingstone's Lualaba, but Capt. Burton regards this outlet as really such only in the season of floods, when it acts as a surplus drain, becoming in turn a tributary to the lake in the dry season; a view which is evidently founded on Livingstone's observation that from February to November the surface water of the lake, as seen at Ujiji, moves northward at the rate of about a mile an hour, while during the remainder of the year there is a similar gentle movement in the opposite direction. — The shores of the lake are rich in beautiful scenery, and in many portions are thickly inhabited. The principal place upon it is the town of Ujiji, on the E. coast.

**TANGIER,** or **Tangiers** (Moorish, *Tanja*), a city and seaport of Morocco, near the W. entrance of the strait of Gibraltar, in lat 35° 47′ N., lon. 5° 48′ W.; pop. about 12,000. It is on high ground overlooking a spacious bay, surrounded by a wall, and defended by several forts. Its streets are narrow and dirty. The harbor was once good, but is now so filled up with sand that vessels of 300 or 400 tons only can enter it. The entrances in 1873 were 525 vessels, tonnage 48,956; clearances 520, tonnage 49,036. The total value of the imports was $1,758,125, of which $600,000 was in specie; of the exports, $1,216,080. Its trade consists principally in supplying Gibraltar, Cadiz, and Lisbon with provisions.—Tangier is the ancient Tingis, supposed to have been founded by the Carthaginians. It was an important city under the Romans, and under Claudius became the capital of Mauritania Tingitana. In 1471 it fell into the hands of the Portuguese, who held it till 1662, when it was ceded to England as a part of the dowry of Catharine of Braganza, queen of Charles II. The British abandoned it in 1684, after destroying the mole which they had built. In 1844 it was bombarded by the French.

**TANGIPAHOA,** a S. E. parish of Louisiana, bounded N. by Mississippi and S. by Lakes Pontchartrain and Maurepas, and intersected by the Tangipahoa river; area, about 720 sq. m.; pop. in 1870, 7,928, of whom 2,994 were colored; in 1875, 7,248, of whom 3,196 were colored. The surface is low and level, and the soil in some parts fertile, in others sandy. It is traversed by the New Orleans, Jackson, and Great Northern railroad. The chief productions in 1870 were 64,023 bushels of Indian corn, 35,809 of sweet potatoes, 1,642 bales of cotton, 20,423 lbs. of butter, 9,071 of wool, and 57,030 of rice. There were 772 horses, 1,480 milch cows, 4,877 other cattle, 3,457 sheep, and 6,270 swine. Capital, Amite City.

**TANJORE. I.** A district of Madras, British India, bounded N. by Trichinopoly and South Arcot, E. and S. E. by the bay of Bengal, S. and S. W. by Madura, and W. by Trichinopoly and the dependent native state of Poodoocottah; area, 3,736 sq. m.; pop. in 1872, 1,975,042. There are no important harbors. The



The Palace, Tanjore.

country is watered by the Coleroon and Cavery and their numerous branches. There are 64 irrigation tanks in the district, and extensive works connected with the rivers, so that the entire area of irrigation in 1872-'3 was 748,673 acres. The surface consists for the most part of an extensive plain of great fertility. Cotton goods are manufactured, and salt is made in the neighborhood of Point Calymere. The inhabitants are nearly all Hindoos, and their institutions have been more perfectly preserved than in most other parts of India. The district forms the inland boundary of the French coast settlement of Carical. **II.** A city, capital of the district, on a branch of the Cavery, 180 m. S. W. of Madras and 45 m. from the bay of Bengal; pop. about 80,000. It contains two forts, the greater about 4 m. in circumference and the lesser about 1 m., both strong and well constructed. The rajah's palace stands in the centre of the great fort. The pagoda in the small fort is considered the finest building of the kind in India. The manufactures consist of silk, muslin, and cotton goods. Tanjore was founded about A. D. 214, and became the capital of a Hindoo principality of the same name, which was absorbed by the Mahrattas in the 17th century. The British assumed the government about the year 1800.

**TANNAHILL, Robert,** a Scottish poet, born in Paisley, June 3, 1774, died May 17, 1810. He worked all his life as a weaver. His volume of "Poems and Songs" (1807) became very popular; but while revising it he fell into a state of despondency, aggravated by the refusal of Constable to print a new edition, burned all his new and revised poems, and drowned himself. An enlarged edition of his remains, with a memoir, was published at Glasgow in 1838, and reprinted at Paisley in 1874.

**TANNIC ACID, or Tannin.** The astringent principles existing in a great variety of plants, which render them capable of combining with the skins of animals to form leather, of precipitating gelatine, of forming bluish black precipitates with the per-salts of iron (or if a free acid be present a dark green color), were formerly termed tannin. These substances, being found to possess acid properties, are now known as tannic acid, and various distinctive names are given to them as they are found of different chemical compositions, though agreeing in their essential properties. Thus the tannic acid derived from the gall nut is termed gallotannic acid; that of the oak, quercitannic acid; of the fustic (*morus tinctoria*), moritannic acid; of the cinchona, quinotannic acid, &c. The principal sources of tannin have been named in the article LEATHER, and the method of extracting it has been particularly described in the article on GALLS, which are the most abundant source of it. Besides this variety, which is the same as that existing in the bark and leaves of many forest trees, fruit trees, and shrubs, and in some roots, as those of the tormentilla and bistort, there is another less known, as the tannin of the catechu and kino, which precipitates the salts of iron dark green instead of blue. Gallotannic acid when pure is a whitish, uncrystallizable solid substance, without odor, intensely astringent to the taste; it dissolves freely in water, to a less extent in dilute alcohol, and sparingly in ether. The best solvent for medical uses is glycerine. It changes blue litmus paper to red, and expels carbonic acid from its compounds with effervescence. Its formula is $C_{27}H_{22}O_{17}$. Its aqueous solution exposed to the air absorbs oxygen, and is converted into gallic acid. Besides its use in tanning, gallotannic acid is employed to produce with the salts of iron the gallotannate of iron, which is the basis of most of the writing inks. It is also employed in medicine for its astringent property, chiefly in checking hæmorrhages, as a wash for ulcers, ophthalmic affections, &c. If taken internally in large quantities, it is an irritant; but in small doses it is absorbed and makes its appearance in the urine as gallic acid, having undergone a process of oxidation in the organism. The combinations of tannic acid with iron and with lead have been applied in the form of ointments to the dressing of ringworms, gangrenous sores, &c.

**TANNING.** See LEATHER, vol. x., p. 275.

**TANSY** (Fr. *athanasie*, contracted to *tanaisie*, from Gr. ἀθανασία, immortality, in allusion

Tansy (Tanacetum vulgare).

to some supposed preservative quality of the plant, or to its durable flowers), *tanacetum vulgare*, a plant of the composite family, a native of Europe, which was formerly cultivated, but has escaped from gardens and become a common roadside weed. It is a perennial herb, with large, twice or thrice pinnately divided, deep green leaves, and stems 2 to 4 ft. high, bearing corymbs of heads of golden yellow flowers, which are nearly all tubular and fertile. A variety called double tansy has the

leaves more cut and crisped. The leaves have a strong fragrance, due to a volatile oil, and a bitter, aromatic taste, and have long been in use infused in spirits as a domestic aromatic tonic; in former times it was held in much esteem as a remedy in dropsy, and as a worm-destroying medicine. The volatile oil is kept in the shops, and is popularly supposed to produce abortion; it is highly poisonous, and its use for criminal purposes has often killed the mother. The green leaves were formerly used in cookery, but have been superseded by foreign spices, though tansy puddings are still made in England.—A native species, *T. Huronense*, found in Maine and on the great lakes, is only of botanical interest.

**TANTALUM.** See Columbium.

**TANTALUS,** a character of Greek mythology, differently described as king of Argos, Corinth, Lydia, or Paphlagonia. Having given offence to the gods, he was punished in the lower world by confinement in a lake, where he was tormented with thirst, yet could not drink, for the waters always receded from his lips. Branches laden with fruit hung over his head, and when he stretched forth his hand to take the fruit the branches withdrew.

**TAOS,** the N. W. county of New Mexico, bordering on Colorado and Arizona; area, about 7,500 sq. m.; pop. in 1870, 12,079. It is watered by the Rio Grande and the Rio de Chama, one of its tributaries, and by the San Juan, a branch of the Colorado, and is crossed by several spurs of the Rocky mountains. Gold mining is carried on to some extent. The chief productions in 1870 were 153,799 bushels of wheat, 80,224 of Indian corn, 21,542 of oats, 15,040 of peas and beans, 2,323 of potatoes, and 90,503 lbs. of wool. There were 1,043 horses, 999 mules and asses, 924 milch cows, 2,600 working oxen, 4,104 other cattle, 81,108 sheep, and 688 swine; 2 flour mills, and 1 quartz mill. Capital, Fernandez de Taos.

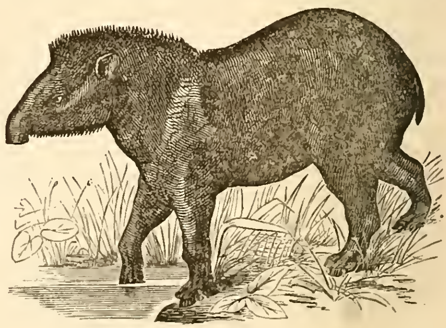
**TAPE GRASS.** See Valisneria.

**TAPESTRY** (Gr. τάπης, a carpet), an ornamental figured cloth, used for lining the walls of apartments, or for covering articles of furniture. The Egyptians and Hebrews attained great skill in ornamenting textile fabrics by colored yarns worked in by the hand, and also by the loom. The art was early introduced into France, and about the 9th century tapestry was made with the loom; but the fabrication with the needle continued as an occupation for ladies of the highest rank. Up to the 12th century the use of tapestry was limited to the adornment of churches and monasteries; but after this period it began to be adopted in dwellings. In France the workmen employed in the manufacture were originally called *sarazins* and *sarazinois*, indicating the origin of the art as derived from the Saracens. The finest work in the 14th and 15th centuries was produced by the Flemings, and about this period the principal manufactories in the west of Europe were at Bruges, Antwerp, Arras, Brussels, Lille, Tournay, and Valenciennes. Florence and Venice at that time produced very rich and costly tapestry; but in the 16th century the more ornamental work with threads of gold and silver was introduced in the manufacture of Fontainebleau. One of the most famous pieces is the Bayeux tapestry, commemorating the Norman conquest of England. (See Bayeux Tapestry.) About the end of the reign of Henry VIII. the art of weaving tapestry was introduced into England. In the reign of James I. the manufacture was established at Mortlake in Surrey under royal patronage. For the earlier designs old patterns were employed, but afterward original scenes were furnished by Francis Cleyn. The method of weaving tapestry in what is called the *haute-lisse* or high warp has been described in the article Gobelins.—See *Notice historique et descriptive sur la tapisserie dite la reine Mathilde*, by the abbé Laffetay (Bayeux, 1874); and "The Bayeux Tapestry, reproduced in Autotype Plates, with Historic Notes by Frank Rede Fowke" (Arundel society, London, 1875).

**TAPEWORM.** See Entozoa, vol. vi., p. 663.

**TAPIOCA.** See Cassava.

**TAPIR** (*tapirus*, Cuv.), a genus of ungulate mammals, characterized by a nose prolonged into a short, movable proboscis; skin very thick and covered with close short hair, the neck furnished with a kind of stiff mane; tail very short; ears small, erect, and pig-like; four toes on the fore and three on the hind feet, separate and ending in nail-like hoofs; skull pyramidal as in the hog, with the nasal bones much arched for the muscles of the proboscis; teeth, 6 incisors and 2 small canines in each jaw, and molars 14 above and 12 below. The tapirs look like hogs, but the legs are longer; they inhabit the moist tropical forests of South America and of the Malayan peninsula and archipelago, usually sleeping by day in retired places, and feeding at night on fruits, grasses, and other vegetable substances, though they



American Tapir (Tapirus Americanus).

are as omnivorous as the hog; like their congeners, they are fond of rolling in the mud and water, and are excellent swimmers; they are gentle and easily tamed; when pursued they

take to the water if possible, where they easily defend themselves with the teeth; on land they do not go by open paths, but break through the thick undergrowth of the woods by their powerful and wedge-like head, in this way escaping the larger carnivora; they have an acute sense of hearing and of sight, and are strong and tenacious of life; their flesh is eaten both in South America and Asia. The best known species is the American tapir (*T. Americanus*, Cuv.), about 6 ft. long and 3½ ft. high, of a uniform brown color, tinged with gray on the head and chest. It is found over almost the whole extent of South America east of the Andes, and its herds sometimes do great mischief by trampling down cultivated fields; it has only one young at a birth, in November. The Asiatic tapir (*T. Malayanus*, Horsf.) is 7 or 8 ft. long, with the hind parts of the body white, and the anterior and the legs black; the trunk is 7 or 8 in. long, the eyes very small, and the rounded ears bordered with white; though the largest, it is the gentlest of the genus. Fossil species are found in the tertiary formations of central Europe.

**TAPPAN, Henry Philip,** an American clergyman, born at Rhinebeck, N. Y., April 23, 1805. He graduated at Union college in 1825, studied at the Auburn theological seminary, was for a year assistant pastor of the Reformed Dutch church in Schenectady, and in 1828 was settled as pastor of a Congregational church at Pittsfield, Mass. In 1832 he was appointed professor of moral and intellectual philosophy in the university of the city of New York. In 1838 the faculty resigned, and for some years he conducted a private seminary. In 1852 he was elected president of the university of Michigan, which post he held till 1863, since which time he has resided chiefly in Europe. His principal works are: "Review of Edwards's Inquiry into the Freedom of the Will" (12mo, New York, 1839); "The Doctrine of the Will determined by an Appeal to Consciousness" (1840); "The Doctrine of the Will applied to Moral Agency and Responsibility" (1841); "Elements of Logic, together with an introductory Review of Philosophy in general, and a preliminary View of the Reason" (12mo, 1844; revised and enlarged ed., 1856); "Treatise on University Education" (1851); and "A Step from the New World to the Old" (2 vols. 12mo, 1852). His three works on the will were republished in Glasgow (1 vol., 1857).

**TAR,** a thick, black, viscid, impure turpentine, procured by burning the wood of *pinus palustris*, *P. sylvestris*, and other species of pine and coniferous trees; also obtained as a product of the destructive distillation of peat, bituminous coals, and shales. It was known to the ancient Greeks, and Dr. Clarke, who describes the method of manufacturing it in the forests of Bothnia, says there is not the smallest difference between the processes there practised and those of ancient Greece. Along the whole coast of the gulf of Bothnia the inhabitants are very generally engaged in this occupation. They make use of the roots of the fir trees, with logs and billets of the same, which they arrange in a conical stack, fitted to a cavity in the ground, generally in the side of a bank. In the bottom of this cavity is placed a cast-iron pan from which a spout leads out through the bank. The heap is covered over with turf, and is then fired, as in making charcoal. Tar collects in the latter part of the process of charring, and runs off through the spout into barrels. Tar is a product where charcoal is the chief object of the process, but is seldom obtained in quantities sufficient to render it an object to collect it, except in charring the resinous woods of the pine family. In Sweden, where the business is also important, some peculiar methods are adopted to increase the yield of tar. Trees of no value for the saw mill are partially peeled of their bark a fathom or two up from the ground, not enough to kill them, but only to check their growth. After five or six years, when cut down, the wood is found to be much richer in resinous matters which produce tar. It is noticed that the condition of the weather during the process of charring may make a difference of 15 or 20 per cent. in the yield of tar. In the United States tar is produced in almost all parts of the country where pitch pine and the *pinus australis* are found. Along the coast of the southern states, especially of North Carolina, Virginia, and Georgia, the business is carried on upon a large scale in connection with the manufacture of turpentine, rosin, and pitch. Old trees which have ceased to produce turpentine, and dead wood which is rich in resinous matter, are selected for the coal pits. The process does not materially differ from that already described. The product is not only sufficient for home consumption, but large quantities are annually exported.—In the preparation of pyroligneous acid, tar is one of the products of the destructive distillation, settling in the bottom of the tanks in which the liquids are collected. The variety known as coal tar is obtained when bituminous matters are distilled for the production of illuminating gas. (See GAS, and PETROLEUM.) Both wood and coal tars are complex mixtures of a variety of liquids holding solid matters in solution or suspension; thus, wood tar contains the hydrocarbons included in the term eupion, and the benzole series of hydrocarbons, including toluole, xylole, cymole, also naphthaline, &c., besides oxidized compounds, including creosote, picamar, kapnomor, &c. Rosin and paraffine are among its solid contents. When its volatile products have been driven off by distillation or boiling, the black carbonaceous residue is known as pitch. The composition of coal tar is materially different, as it contains all the great variety of products derived from the destructive distillation of bituminous coal as obtained from the gas works. Coal tar, a refuse product of these works, may be considered in

general as consisting of from 3 to 15 per cent. of light oils, from 60 to 67 per cent. of heavy oils, usually termed "dead oil," and from 18 to 35 per cent. of pitch; the best coals, as the cannel and boghead, produce tar richer in light oils, and yield least pitch.—Wood tar is thick and hard in cold weather, and softens when warm so as to flow like thick molasses. Its specific gravity is about 1·04. It is boiled down to produce pitch, is used to coat the bottoms of vessels to render them water-tight, and to cover rigging of ships to preserve it from the action of the weather, and is a useful lubricant for the journals of wheels. In medicine it is used internally in chronic catarrhs, and in some cutaneous diseases, as ichthyosis. The inhalation of its vapor is recommended in cases of bronchial disease, the air of a room being impregnated with it by moderately heating the tar placed in a cup over a lamp. It has been found beneficial as an external application to ulcers and various diseases of the skin. It is administered in pills mixed with flour, or in an electuary of tar and sugar. It yields a portion of its properties to water with which it is stirred, and this preparation, known as tar water, is administered as a stimulant and diuretic, and is applied as a wash in chronic cutaneous affections.—Coal tar has an exceedingly repulsive odor, and was long considered of no value; but it has been found that the light oils obtained by its distillation may be made to furnish a variety of singular products, possessing rare properties, and affording the rich colors applicable to dyeing, known as the aniline colors (see ANILINE, BENZOLE, and MAUVE), and also flavors of various essences and agreeable perfumes. The dead oil is frequently burned for the production of lampblack. One of its most useful products is carbolic acid. (See CARBOLIC ACID.) Coal tar is now in common use as a coating for iron work exposed to the weather, and is used with asphalt and other substances to form a tight covering for roofs and the walls of vaults, &c. Its use in preparing a fuel with the dust of mineral coal is noticed in FUEL, vol. vii., p. 518.

**TAR**, a river of North Carolina, which rises in Person co. and flows S. E., passing Tarborough, Greenville, and Washington, and discharges into Pamlico sound by an estuary called Pamlico river. Its length is 140 m., or including Pamlico river 180 m., and it is navigable for small steamers to Tarborough, 85 m. from the sound.

**TARANTO** (anc. *Tarentum*), a city of S. Italy, in the province of Lecce, in Apulia, 44 m. W. S. W. of Brindisi; pop. in 1872, 27,546. It stands on an island at the N. end of the gulf of Taranto, and is connected with the mainland by two bridges. The inner harbor (*mare piccolo*), 12 m. in circumference, is useless as a roadstead, and ships must anchor in the outer harbor (*mare grande*), which is much exposed. The castle and fortifications, built by Charles V., command both harbors. Taranto is the seat of an archbishop, and has a cathedral dedicated to St. Cataldus, an Irishman and the first bishop of Tarentum, about 166. Linen and cotton stockings are made here, and gloves from the byssus of the mollusk *pinna marina*.—Tarentum was colonized by exiles from Sparta in 708 B. C. Its harbor was then the best on the coast. It became a large and powerful city, and 14 other towns were subject to it. It carried on long contests with the Messapians and Peucetians; and about 474 its army suffered a disastrous defeat from the former, in which so many of its nobles were killed that its government, previously an aristocracy, was thereafter democratic. It was predominant in the league of the Greek cities of Italy against Dionysius of Syracuse and the Lucanians. Rome declared war against it in 281. The Tarentines called in Pyrrhus, king of Epirus, after whose defeat and withdrawal from Italy the city surrendered to the consul Papirius in 272, while a Carthaginian fleet was approaching to its relief, and thereafter continued subject to Rome. During the second Punic war the citizens betrayed it into the hands of Hannibal, who held it for more than two years, but was unable to dislodge the Roman garrison from the citadel. In 209 Fabius Maximus retook the city and gave it up to plunder, after putting the Carthaginians to the sword. It continued to be the chief town of S. Italy under the empire. The present town occupies only the site of the ancient citadel, which was originally a promontory, but was made an island by Ferdinand I. of Naples.

**TARANTO, Duke of.** See MACDONALD.

**TARANTULA**, or **Tarentula**, a terrestrial hunting or wolf spider of S. Europe, belonging to the genus *lycosa*, the *L. tarentula* (Latr.). It is the largest of European spiders, measuring 1½ to 2 in. in the length of the body; the color is ashy brown above, marked with gray on the thorax, and with triangular spots and curved streaks of black bordered with white on the abdomen; below saffron-colored, with a transverse black band. It received its popular name from being common in the vicinity of Taranto in S. Italy. It makes no web, wandering for prey, which it runs down with great swiftness, and hiding in holes in the ground and crevices lined with its silk; it has one spiracle on each side, one pulmonary sac, and eight eyes. Its bite was once considered highly poisonous, producing the nervous febrile condition called tarantism, which was supposed to be curable only by dancing to lively music until the person fell exhausted.—The *L. Carolinensis* (Bosc) is called tarantula in the southern states; it attains a length of 2 in. with an extent of legs of 4 in.; it is mouse-colored above, with white sides and whitish dots and lines on the abdomen; below blackish; legs whitish tipped with black. It makes deep excavations in the ground, which it lines with silk; the females carry their young on the back. Its poison is active, and might cause troublesome symptoms in man

if the fangs could be opened at an angle proper to pierce his skin. The great hairy spiders of the genus *mygale* are called tarantulas in the southwestern states, and are destroyed by the large red-winged wasp, *pompilus formosus*.

**TARARE,** a town of France, in the department of the Rhône, on the Tardine, 21 m. N. W. of Lyons; pop. in 1872, 13,694. It is situated at the foot of Mount Tarare, and is celebrated for its muslin manufactures.

**TARASCON** (anc. *Tarasco*), a town of France, in the department of Bouches-du-Rhône, on the left bank of the Rhône, 10 m. N. of Arles and 50 m. N. W. of Marseilles; pop. in 1872, 12,454. It is connected with Beaucaire, on the opposite side of the river, by one of the finest suspension bridges in France. It contains a magnificent castle of the counts of Provence, on a rock overhanging the river, built in the 15th century on the site of a temple of Jupiter, and now used as a prison. The church of St. Martha is a Gothic edifice commenced in the 15th century, with a richly sculptured entrance and a crypt with remarkable tombs and a marble statue of St. Martha. Silk, woollen, and cotton goods are manufactured.

**TARBES,** a town of France, capital of the department of Hautes-Pyrénées, beautifully situated on the left bank of the Adour, 23 m. E. S. E. of Pau; pop. in 1872, 16,565. It is the seat of a bishopric dating from about A. D. 400, and has a modern cathedral built on the site of the castle of Bigorre. It was injured during the middle ages by successive invaders, and was twice burned by the Huguenots in the 16th century.

**TARDIGRADES.** See SLOTH.

**TARE.** See VETCH.

**TARENTUM.** See TARANTO.

**TARGUMS** (Chal. *targem*, to translate), the general name given to the Chaldee, or more accurately Aramaic versions and paraphrases of the Hebrew Scriptures. On account of the many vicissitudes of the Jewish people in the course of their history, and more especially on account of their long captivity in the Babylonian empire, the knowledge of the ancient Hebrew language had gradually declined, and Aramaic had become the language of the people. Hence after the time of Ezra, whenever the Scriptures were read in public by the priest, an interpreter (*meturgeman*) translated them into the Aramaic. This translation it was forbidden to reduce to writing; but the rule was gradually violated, and by the end of the 2d century A. D. the practice of writing translations or "targums" had become fixed. The work of collecting and comparing the versions of individual translators, and reducing them to one, was probably accomplished about the end of the 3d century. The oldest and best of the targums is on the Pentateuch, usually called the "Targum of Onkelos," or "of Onkelos the proselyte." The existence of Onkelos, and his name, have been fruitful themes of discussion among Biblical scholars, but it is now pretty generally agreed that he had nothing whatever to do with the targum attributed to him. Its language is Chaldee, very similar to that of the book of Daniel, and as faithful to the original as its destination as a version for the people would permit. A principal feature is its careful avoidance of all anthropomorphic expressions. Its final redaction probably took place about A. D. 300, and in Babylonia. The targum second in time and importance is that called the "Targum of Jonathan ben Uzziel," or "Targum on the Prophets," embracing Joshua, Judges, Samuel, Kings, Isaiah, Jeremiah, Ezekiel, and the twelve minor prophets. It probably originated in Palestine, and was completed in Babylon about the middle of the 4th century. There is no evidence that Jonathan ben Uzziel ever had anything to do with it, and it was undoubtedly the work of many hands. The third and fourth targums are essentially one work. The former, embracing the whole Pentateuch, is the later, and is called like the second the "Targum of Jonathan ben Uzziel;" but as he could not possibly have had any connection with it, it is often called the "Targum of Pseudo-Jonathan." The fourth, called "Targum of Jerusalem," a name originally common to both this and the third, embraces portions of each of the books of the Pentateuch. The "Targum of Pseudo-Jonathan" is an emended and completed edition of the "Targum of Jerusalem," the latter being itself a collection of emendations, amplifications, &c., to the Targum of Onkelos. They originated in Syria or Palestine in the latter half of the 7th century. The fifth class of targums are on the Hagiographa, and are usually called "Targums of Joseph the Blind," who had undoubtedly been dead many centuries when they were written. They probably originated in Syria some time between the 9th and 12th centuries. They embrace: 1. Proverbs, Job, and Psalms. The targum of Proverbs is both faithful and complete; those of Job and the Psalms are mere collections of fragments. 2. Targums on the Song of Songs, Ruth, Lamentations, Esther, and Ecclesiastes. They appear to be all by one author, but their differences from the originals are so great that they can hardly be called versions. Their dialect is about equally related to East and West Aramæan. 3. Two targums on Esther. One of these, known as the second targum, is for the most part a collection of tales and legends. The sixth targum is on Chronicles, and appears to have been made in Palestine at a very late period. The seventh targum, according to the enumeration of Deutsch, is on Daniel, has been known only within the last 30 years, and exists so far as known only in a translation of a portion of it into Persian. It is not usually included in the list of targums. The eighth targum is on the apocryphal portions of Esther, and has no particular value. Many fragments of lost targums are scattered in va-

rious works of Semitic literature. There is no edition of any of the targums which deserves to be called critical. Most of them are included in the large polyglot editions of the Bible, and a much improved edition of the "Targum of Onkelos" was published at Wilna in 1852. —For an extended discussion of the targums, condensing almost all the learning of the subject, see E. Deutsch's "Literary Remains" (New York, 1874).

**TARIFA,** a town of Spain, in the province of Cadiz, Andalusia, on the southernmost point of the kingdom, in lat. 36° 3′ N., lon. 5° 35′ W., 52 m. S. E. of Cadiz, and 25 m. S. E. of Cape Trafalgar; pop. about 12,000. It is surrounded by old walls and towers, and has a strong fortress. A Moorish castle within the walls is now used as a prison. Tarifa was named from Tarif ibn Malek, a Saracen chief who landed here from Africa in 710, a year before the great Moorish invasion of Spain. During the Moorish domination all vessels passing through the straits of Gibraltar were here compelled to pay duties; whence the word tariff. In 1292 Sancho the Brave of Castile captured it, and Alonso Perez de Guzman held it against the Moors in 1294. About 1340 the Moors besieged it again, but were driven away by the kings of Castile and Portugal. In 1811 it was garrisoned by 1,200 British troops and 600 Spaniards, who held it from Dec. 19 to Jan. 4, 1812, against 13,000 French troops. The French captured the place in 1823.

**TARLETON, Bannastre,** an English soldier, born in Liverpool, Aug. 21, 1754, died Jan. 23, 1833. He was a lieutenant colonel in Cornwallis's army, and raised in this country a troop called the British legion, which contributed largely to British successes in the south. He massacred Col. Buford's regiment, stationed on Waxhaw creek, May 29, 1780, and "Tarleton's quarter" became a synonyme for cruelty. In 1781, with 1,100 men, he attacked an inferior American force near the Cowpens under Gen. Morgan, and was defeated. He was with Cornwallis during the rest of the war, and was present at the surrender of Yorktown. After his return to England he was promoted to the rank of colonel, and was so popular that in 1790 he was sent to parliament free of expense from his native town. In 1817 he received the commission of major general. He was created a baronet, Nov. 6, 1818. He published a "History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America" (4to, London, 1787).

**TARN,** a S. department of France, in Languedoc, bordering on the departments of Aveyron, Hérault, Aude, Haute-Garonne, and Tarn-et-Garonne; area, 2,217 sq. m.; pop. in 1872, 352,718. The S. E. part is mountainous, and the rest of the department is traversed by hills. The principal river is the Tarn, a tributary of the Garonne, which receives the Aveyron, Tescou, and Agout; and near Albi there is a series of falls called Saut-du-Tarn. Coal, iron, lead, copper, gypsum, and porcelain and potters' clay are found. The vine is cultivated, and much brandy is made. Woollen, cotton, and silk goods, iron, leather, and paper are manufactured. It is divided into the arrondissements of Albi, Gaillac, Castres, and Lavaur. Capital, Albi.

**TARN-ET-GARONNE,** a S. department of France, in Guienne, bordering on the departments of Lot, Aveyron, Tarn, Haute-Garonne, Gers, and Lot-et-Garonne; area, 1,436 sq. m.; pop. in 1872, 221,610. The whole department belongs to the basin of the Garonne, and the surface has a gradual slope to the west. The Garonne, Tarn, and Aveyron are all navigable in this department. Iron, coal, and marble are found. About two thirds of the surface is arable, one tenth is forest, and one tenth is devoted to the vine, the wine being excellent. The mulberry for rearing silkworms is extensively cultivated. Mules and poultry are reared in great numbers and are a principal source of wealth. The minerals include iron and some coal and marble. Woollen, linen, and silk goods, cutlery, iron, and beet sugar are manufactured. The department is divided into the arrondissements of Montauban, Moissac, and Castelsarrasin. Capital, Montauban.

**TARPEIA,** a Roman maiden, the daughter of Spurius Tarpeius, who, according to the legendary history of the period, was governor of the citadel on the Capitoline hill when the Sabines invested Rome. Tarpeia saw and admired the bracelets of the Sabines, and offered to betray the citadel to them for "what they wore on their left arms." She opened the gate at night, and as they passed in they threw upon her their shields, which were worn on the left arm, and crushed her. She was buried on that part of the hill called the Tarpeian rock.

**TARQUIN. I. Lucius Tarquinius Priscus** ("the Elder"), fifth king of Rome, assassinated about 578 B. C. According to the common story, his father was a Corinthian nobleman named Demaratus, of the family of the Bacchiadæ, who fled on the overthrow of his order by Cypselus and settled at Tarquinii in Etruria. The son, whose original name was Lucumo, inherited great wealth, married a noble Etruscan woman named Tanaquil, who was skilled in augury, and at her instigation removed to Rome to seek a higher career than any within his reach in Etruria. He gained the confidence of King Ancus Marcius, became guardian to his children, and on the king's death was elected to the vacant throne, about 616. He destroyed the Sabine town of Apiolæ, and subdued a number of Latin towns. His greatest exploit was the defeat of the Sabines, who advanced to the gates of Rome, but were driven back and at length completely overthrown upon the Anio. He built the vast sewers which drained the lower part of the city, and are still perfect; laid out the Circus Maximus, and instituted the Roman games; assigned the shops in

the forum to private citizens; and began to surround the city with a stone wall, which his successor finished. Under Tarquin 100 new members (the *patres minorum gentium*) were added to the senate, and the number of the vestal virgins was increased from four to six. The sons of Ancus Marcius, fearing that he would secure the succession to his son-in-law Servius Tullius, planned his death. (See SERVIUS TULLIUS.) **II. Lucius Tarquinius Superbus** ("the Proud"), the seventh and last king of Rome, son of the preceding, died about 495 B. C. About 534 he formed a conspiracy, murdered Servius Tullius, and usurped the throne. He immediately, as the semi-legendary story of his reign has it, abolished all the privileges that Servius had given to the plebeians, decreed the death of the senators who had supported them, took the whole administration of justice into his own hands, and put to death or exiled all who were obnoxious to him. The senate was seldom consulted, and its vacancies were not filled. Under him the Latin league was joined by the Hernici and by two Volscian towns, and Rome became the head of the confederacy. With the spoils from the wealthy city of Suessa Pometia he began the erection of the capitol. He subdued Gabii, a Latin city which refused to enter into the league, and about 510 besieged Ardea. While Tarquinius Collatinus, son of Aruns, the brother of Tarquinius Priscus, was with the army before this city, his cousin Sextus Tarquinius, the king's son, went to his house at Collatia, and there violated his wife Lucretia. Lucretia sent to the camp at Ardea, and summoned thence her father and her husband. With them came Lucius Brutus. To these three she told what had happened, enjoined them to avenge her, and stabbed herself with a dagger. Brutus led the way into the market place, whither the corpse was carried, summoned the people, and related the occurrence. So great was the hatred already entertained of the Tarquins and the indignation now excited, that a decree was immediately passed by which the king was deposed, and his family banished from the city. Tarquin hastened to Rome, but found the gates closed against him. Brutus repaired to Ardea, where he was received with joy, and the army renounced its allegiance to the tyrant. Tarquin took refuge at Tarquinii, and thence sent ambassadors to Rome to demand his private property. These ambassadors conspired with some young nobles for the restoration of the king, but were discovered, and with their confederates—among them two sons of Brutus—were executed, and Tarquin's private property was given up to plunder. He now formed an alliance with the Etruscan cities of Tarquinii and Veii, and endeavored to recover the throne by force, but was defeated near the forest of Arsia. He next obtained the assistance of Lars Porsena of Clusium, who marched against Rome with a great army. (See PORSENA.) Finally the whole Latin confederacy espoused the cause of Tarquin against Rome, and the contest was decided by the Roman victory in the battle of Lake Regillus, about 498. Tarquin retired to Cumæ, and there died.

**TARRAGON** (Lat. *dracunculus;* Span. *taragona*), an aromatic herb (*artemisia dracunculus*) belonging to the *compositæ*, and in the same genus with the common wormwood, but differing from this and most other species in having undivided leaves. It is a native of Siberia and the region of the Caspian sea, and is much cultivated in European, and sparingly in American gardens. It is a perennial, with stems 2 to 3 ft. high, and bears upon the upper branches small heads of inconspicuous flowers, which in cultivation are infertile; the long, narrow, and smooth leaves have an aromatic odor and a taste somewhat like that of anise. The French, who call it *estragon*, consider the leaves or young shoots essential to the proper dressing of some salads, and use it also to flavor vinegar, pickles, and mustard, and in other compounds. Tarragon vinegar is made by simply infusing the leaves in strong vinegar. The plant is perfectly hardy in this country.

**TARRAGONA. I.** A N. E. province of Spain, in Catalonia, bordering on the Mediterranean and the provinces of Lérida, Barcelona, Castellon, Teruel, and Saragossa; area, 2,451 sq. m.; pop. in 1870, 350,395. The province is traversed from N. to S. by the Prades mountain range, which has numerous offsets that extend to the coast, and the intervening valleys are very fertile. The only river of importance is the Ebro. There are mines of lead, copper, silver, and manganese, and the hills are covered with pine, cork, and oak. Good wine is produced, and there are many manufactories of silk, woollen, velvet, and cotton goods, oil, soap, pottery, and brandy. **II.** A city (anc. *Tarraco*), capital of the province, on the Mediterranean, at the mouth of the Francoli, 273 m. E. N. E. of Madrid; pop. about 18,000. It is fortified, and consists of two parts, the high and the low. It is the seat of an archbishop. There are schools of navigation and design, and an ecclesiastical seminary. The mole, begun in 1790 and finished in 1874, is 4,242 ft. long. The exports to the United States for the year ending Sept. 30, 1874, chiefly wine, nuts, and liquorice, amounted to $286,212.—The town is supposed to have been originally settled by the Phœnicians. Under the Romans it was the capital of Hispania Tarraconensis, and is said to have contained 1,000,000 inhabitants. There are remains of a Roman amphitheatre and aqueduct. It was captured by the Goths, was destroyed by the Moors under Tarik, and remained uninhabited for four centuries. It was captured by the British in the war of succession. In 1811 the French under Suchet took it by storm. In the middle ages a number of church councils were held in Tarragona.

**TARRANT**, a N. W. county of Texas, intersected by the West fork of Trinity river; area,

900 sq. m.; pop. in 1870, 5,788, of whom 705 were colored. The surface is undulating, partly timbered and partly prairie, and the soil fertile. The chief productions in 1870 were 29,587 bushels of wheat, 203,595 of Indian corn, 72,635 of oats, 12,995 of sweet potatoes, 41,669 lbs. of butter, and 728 bales of cotton. There were 6,953 horses, 4,099 milch cows, 14,946 other cattle, 4,205 sheep, and 13,052 swine. Capital, Fort Worth.

**TARRYTOWN,** a village in the town of Greenburgh, Westchester co., New York, on the E. bank of the Hudson river where it widens into the Tappan Zee, and on the Hudson River railroad, 26 m. N. of New York city; pop. in 1875, 6,500. It is very picturesque, and contains a large number of elegant country seats. It is celebrated as the scene of the capture of Major André in 1780, and contains a monument commemorative of that event. South of the village is Sunnyside, the residence of Washington Irving, whose grave is in the Sleepy Hollow cemetery, near the old Dutch church. The village contains a silk factory, a boot and shoe factory, a steam pump factory, a tool factory, a sash and blind factory, a national bank, a savings bank, several public schools, two female seminaries, two boarding schools for boys, a weekly newspaper, and 11 churches.

**TARSHISH,** the name of an ancient emporium, or, according to some critics, more than one, as some of the passages of Scripture in which it is mentioned appear to indicate that it was W. and others E. of Palestine. There are 25 or 30 references to it in the Scriptures. Tartessus in Spain, Tarsus in Cilicia, the island of Thasos in the Grecian archipelago, Carthage, some seaport of the British isles, and Point de Galle in Ceylon have all been urged as fulfilling certain conditions of the Scriptural references. The following facts concerning it are gleaned from various passages of Scripture. It was largely engaged in commerce, and probably in ship building; it is several times spoken of as an island or seacoast; it had large traffic with Tyre and Sidon, especially in gold and silver, tin, iron, and lead; it is usually represented as W. of Palestine and of Tyre, and its ships are spoken of as broken by an E. wind. Yet we are told distinctly in 2 Chron. ix. 21, that Solomon's ships went to Tarshish with the servants of Hiram, returning every three years, and bringing "gold and silver, ivory, and apes, and peacocks;" and that Jehoshaphat joined with Ahaziah in building ships at Ezion-geber, a place on the Elanitic gulf of the Red sea, to go to Tarshish (2 Chron. xx. 36), while the corresponding passages in 1 Kings (ix. 26–28, x. 22, xxii. 48) say that Tarshish vessels were built at Ezion-geber and sent to Ophir, whence they brought "gold and silver," &c. This apparent discrepancy has been explained in three ways: 1 (which is most plausible), that the name "ships of Tarshish" does not necessarily imply that the ships were built at Tarshish or intended to ply between that and some other port, but designated a peculiar style of ships, and that hence ships intended for a long coast voyage were called "ships of Tarshish" from their resemblance to the Phœnician model; 2, that the ships built at Ezion-geber were really intended for the trade to Tarshish (Tartessus) in Spain, and were to be transported across the isthmus of Suez to the Mediterranean; and 3, that there were two and possibly more places called Tarshish.

**TARSUS,** a city of Asiatic Turkey, in the vilayet and 20 m. W. S. W. of the city of Adana, on the right bank of the Cydnus, about 10 m. from the Mediterranean; pop. about 8,000. It stands in a fertile plain, and is well built of stone. It has an ancient church, several mosques, handsome caravansaries, and public baths. Wheat, barley, cotton, copper, and gall nuts are exported.—Tarsus is said by the ancients to have been founded by Sardanapalus. It was taken by Alexander, and under the Romans rivalled Athens, Antioch, and Alexandria. It was the birthplace of the apostle Paul and of several Greek philosophers, poets, and grammarians.

**TARTAR** (named from Tartarus, the infernal regions, according to Paracelsus, on account of its fiery heat; also called argol), the crude bitartrate of potash, precipitated from wines as they ferment, being set free as alcohol is produced, in which it is insoluble. When purified it is known as cream of tartar or bitartrate of potassium. Salt of tartar is a name often given to pure carbonate of potash. Soluble tartar is a name given to the normal or neutral tartrate of potassium, used in medicine as a cooling purgative. (See POTASSIUM, vol. xiii., p. 763.)—Tartar is also the name of an incrustation upon the teeth, composed, according to Berzelius, of salivary mucus 13·5, animal matter soluble in muriatic acid 7·5, and phosphate of lime (earthy phosphates) 7·9.

**TARTAR, Cream of.** See CREAM OF TARTAR.

**TARTAR EMETIC,** a double tartrate of antimony and potassium. (See ANTIMONY.)

**TARTARIC ACID,** an organic tetratomic acid, which is now regarded as belonging to a group derived from corresponding tetratomic alcohols by the substitution of oxygen for hydrogen molecules. Only one of the acids, the erythric ($C_4H_8O_5$), has been actually formed, from erythrite ($C_4H_{10}O_4$), but the composition and behavior of tartaric acid favors the theory that it has a similar derivation. The formula of tartaric acid is $C_4H_6O_6$, and includes four bibasic acids having different crystalline forms, and different properties in regard to polarized light, viz.: dextrotartaric acid, which turns the plane of polarization to the right; lævotartaric acid, which turns it to the left with equal force; paratartaric or racemic acid, which has no rotatory power, but is separable into two equal parts of right-handed and left-handed acids; and an inactive acid not thus separable.

Dextrotartaric acid is the ordinary tartaric acid found in grapes, tamarinds, pineapples, and several other fruits, usually in combination with potassium, and frequently with a small portion of calcium. The acid of commerce is prepared from tartar or argol, and was first separated from it by Scheele in 1770. The present mode of manufacture is as follows. The crude tartar is dissolved in hot water in which is stirred a little pipe clay and bone black to remove coloring matter. The filtered or decanted liquid deposits on cooling crystals of cream of tartar, from which the acid may be prepared by dissolving them in boiling water, or the original solution may be employed. Powdered chalk is added as long as there is effervescence or the liquid reddens litmus. The product consists of an insoluble tartrate of calcium and a soluble normal tartrate of potassium, which latter, after separation of the calcium salt, is mixed with an excess of chloride of potassium, which throws down the remaining tartaric acid also as tartrate of calcium. Both precipitates are washed and digested with sulphuric acid diluted with eight or ten parts of water, by which means sulphate of lime is precipitated while the tartaric acid is left free in the solution. The filtrate is carefully evaporated to the consistency of a sirup, and placed in a warm situation to crystallize. Liebig found that tartaric acid is produced by the action of nitric acid upon milk sugar. It may also be obtained from succinic acid by submitting the latter to the action of bromine and treating one of the products, dibromosuccinic acid, with oxide of silver and water. Tartaric acid crystallizes in transparent, oblique rhombic prisms of sp. gr. 1·75, which are inodorous, permanent in the air, and easily soluble in hot and cold water and in alcohol, but insoluble in ether. The aqueous solution soon spoils, becoming covered with a fungoid growth. Tartaric acid is used in calico printing to liberate chlorine from bleaching powder, and in medicine, principally for the preparation of effervescing powders. (See EFFERVESCENCE.)—*Other Varieties of Tartaric Acid.* The grapes cultivated in certain districts of the upper Rhine and in the Vosges contain, besides ordinary tartaric acid, an isomeric acid, called paratartaric or racemic acid, which resembles it in many particulars, but differs much in others; for instance, it is rather less soluble, and has not the power of rotating the plane of a polarized ray of light. Pasteur has made some interesting researches upon the subject, and finds that if racemic acid is united with single bases, a salt is formed whose crystals are all identical; but if it is united with two bases, after the manner of Rochelle salt, and the solution allowed to crystallize slowly, two varieties of crystals are formed, bounded by the same number of faces, inclined to one another at exactly the same angles. They however have certain hemihedral faces which are developed on opposite sides of the two crystals, so that one crystal is like the reflected image of the other, and may be denominated morphologically right-handed and left-handed crystals. If these crystals are selected and separately recrystallized, each variety will produce its own particular form of crystal, and one will have right-handed and the other left-handed rotatory powers on polarized light. The acids obtained from these two varieties of crystals have also corresponding right-handed and left-handed rotatory powers, one being in fact ordinary or dextrotartaric, the other lævotartaric acid. As these two acids have equal rotatory powers in opposite directions, if their solutions are mingled in equal proportions the mixture will have no effect upon polarized light. When concentrated solutions of the two acids are mingled, crystals of racemic acid are deposited with sensible evolution of heat. Both acids also exhibit pyro-electricity, but in opposite directions. Pasteur also found that racemic acid may be artificially produced by the action of heat upon certain compounds of tartaric acid which are capable of resisting a high temperature; for instance, when tartrate of cinchonine is exposed to a temperature of about 338° F. and afterward repeatedly boiled in water and treated with chloride of calcium, racemate of calcium is formed. Left-handed tartaric acid may in like manner be converted into racemic acid. The formation of racemic acid in these reactions is accompanied by the production of a fourth modification, which Pasteur calls inactive acid, having, like racemic, no action on polarized light, but which, unlike racemic, cannot be resolved into right-handed and left-handed acids.

**TARTARS**, a branch of the Mongolian or Turanian division of the human race, principally inhabiting Asia. The name is one of indefinite and indiscriminate application, used with varying comprehensiveness by different writers. In its widest sense it may be regarded as embracing the Altaian group of Mongolians, according to Virchow; that is, all the various tribes and nations inhabiting the table lands of central and northern Asia who are not of Aryan blood, including the Tartars proper, the Kirghiz, the Calmucks, the Mantchoos (sometimes called the Mantchoo Tartars), the Mongols proper, or people of Mongolia (who, however, probably constitute a separate branch), and the Tungusians, who are thought by Huxley to share the physical characteristics of the Esquimaux. In a more restricted application of the word, the Tartars comprise the Turanian inhabitants of Turkistan and the adjacent regions. These are the nomad Kirghiz, who dwell in Khokan and Kashgar, on the Pamir steppe, and in the adjacent valleys; the Uzbecks, who have advanced furthest toward settled civilization and constitute the governing class in Turkistan; the Kiptchaks, a semi-nomadic people living in Khokan, who travel with their flocks

during the grazing season; the Buddhist Calmucks of eastern Turkistan, extending into Dzungaria; the Kazaks, in the region of the Sir Darya; and many smaller tribes. The predatory Turkomans inhabiting the country E. of the Caspian, from the Oxus to the Persian frontier, are of Tartaric origin, although the pure Tartar features are preserved in but few of the tribes, owing to the large admixture of Aryan blood. The characteristic Tartar physiognomy appears most distinctively at the present day among the Kirghiz, who have high cheek bones, noses thick but depressed, narrow eyes, and little or no beard. Almost every grade of variance from this type, however, is met with. In central Asia, the word Turk is used as synonymous with Tartar, merely to indicate Mongolians. According to Col. Yule, the two classes of people whom Marco Polo would identify with Gog and Magog represent the two genera of the Tartar race, namely, the White Tartars, or Turks, and the Black Tartars, or Mongols proper, who formed the bulk of the followers of Genghis Khan. Indeed, the name Mongol (bold), which he is said first to have given to the tribes who followed his standard, has been regarded as directly derived from Magog.—The word Tartar or Tatar (also Ta-ta) appears to be of Chinese origin, and was applied to early invaders of China from the upper Amoor region. They were a warlike and savage race; and possessing vast numbers of horses, they often descended upon the peaceable Chinese, and plundered their villages. Their predatory characteristics came to be so closely associated with their name as to lead to its eventual application to numerous other robber hordes. The Altai mountains appear to have been the centre of the great Mongolian migratory movement which began in the 4th century and lasted until the 10th, extending over the neighboring Asiatic countries, and under Attila far into Europe, where its results may still be traced in the Tartar population of eastern and southern Russia. The vast military expeditions of Genghis Khan and Timour were subsequent movements of a like character. Shamanism was the original faith of the Mongols. This was succeeded by Buddhism, which was abandoned for Lamaism about the end of the 16th century. Sunni Mohammedanism is now professed by the western Tartars generally, both in Asia and Europe.

**TARTARUS**, in the Grecian mythology, a son of Æther and Gæa, and the father of the giants Typhæus and Echidna. In the Iliad Tartarus is a place as far below Hades as heaven is above the earth, and there by later writers the spirits of the wicked are said to be punished. By the later poets also the name is often used synonymously with Hades.

**TARTARY**, a geographical designation now usually limited to Turkistan and the adjoining regions, but formerly of much wider signification, embracing a broad belt stretching across the centre of the Asiatic continent from the Japan and Okhotsk seas on the east to the Caspian on the west, and according to some geographers extending westward into Europe as far as the river Don. Tartary in its most extended sense therefore includes, in Asia, Mantchooria, Mongolia, Dzungaria, East Turkistan or High Tartary, Turkistan proper, including Khokan, Bokhara, and Khiva (formerly known as Independent Tartary), and all the southern part of the Russian possessions in Asia; and in Europe, the greater part of the Russian governments of Orenburg, Astrakhan, and Yekaterinoslav, the Don Cossack territory, and the Crimea, the last of which was formerly called Little Tartary, and also Crim Tartary, from the name of the horde which settled there in the 13th century. The name Tartary, however, is now seldom applied to any region outside of that bounded N. by Siberia, E. by Mantchooria, S. by China proper, Thibet, India, Afghanistan, and Persia, and W. by the Caspian sea.

**TARTINI, Giuseppe**, an Italian violinist, born at Pirano, Istria, in 1692, died in Padua in 1770. He gave up law and theology, acquired unrivalled proficiency as a violinist, eloped with one of his pupils, and lived for two years concealed in the convent of Assisi. There he diligently studied music, and being at length forgiven, came out of the convent the best player in Europe. Among his celebrated pupils were Pagin, La Houssaye, and Pugnani. His most remarkable composition is his *Sonate du diable*, or "Tartini's Dream."

**TARTRATES**, salts formed by the union of tartaric acid with bases. Tartaric acid is dibasic, and forms with monatomic metals acid salts, like bitartrate of potassium, $KHC_4H_4O_6$; normal salts, like normal potassic tartrate (soluble tartar), $K_2C_4H_4O_6$; and double salts, like sodic-potassic tartrate (Rochelle salt), $NaKC_4H_4O_6$. With diatomic metals it forms normal salts, like normal basic tartrate, $BaC_4H_4O_6$, and double salts consisting of a double molecule of the acid in which two atoms of hydrogen are replaced by a diatomic and two atoms by a monatomic metal, like baric-potassic tartrate, $BaC_4H_4O_6,K_2C_4H_4O_6+2H_2O$. With triatomic metals it forms a peculiar class of salts, well illustrated in the case of the antimony salts, as normal antimonious tartrate, $(SbO)_2C_4H_4O_6$; acid antimonious tartrate, $SbO,C_4H_5O_6$; and potassio-antimonious tartrate, tartar emetic, $KSbOC_4H_4O_6$. Many of the tartrates are used in medicine, and several are employed in calico printing and dyeing, as the tartrate of chromium and the tartrate of potassium and tin. The principal medicinal tartrates are the double salts, tartar emetic and Rochelle salt. (See ANTIMONY, and ROCHELLE SALT.) The tartrates of the alkalies are oxidized in the animal system to bicarbonates, so that the administration of tartrate of potassium renders the urine alkaline. The acid alone, on the other hand, is more efficient than the mineral acids in acidifying this excretion.

**TARUDANT,** the chief city of the province of Sus, Morocco, in the valley of the Sus, about 44 m. from the Atlantic coast, and 140 m. S. W. of Morocco; pop. estimated by Rohlfs at 30,000 to 40,000. It lies near the foot of the S. slope of the Atlas, about 4 m. from the right bank of the river Sus. The country around it is highly cultivated, and it is surrounded by gardens and palm groves. The wall, enclosing a large area, much of which is occupied by gardens, is flanked by towers and entered by five gates. The *kasba* or citadel occupies an angle on the E. side. The streets are crooked, narrow, and impracticable during rains. There are three principal mosques and many smaller ones, two prisons, and several fountains. The dwelling houses are mostly of one story. Tarudant is noted for its leather and dye works, and for manufactures of copper, mostly pots and kettles, which are exported as far as Timbuctoo, Kuka, and Kano. It was formerly celebrated for sugar culture, but the plantations no longer exist. The inhabitants are rude and intolerant to Christians.

**TASCHEREAU, Jules Antoine,** a French author, born in Tours, Dec. 19, 1801, died in Paris, Nov. 11, 1874. He was one of the editors of the *National*, and for a short time after the revolution of July, 1830, he was secretary general of the prefect of Paris and a member of the council of state. Subsequently he became one of the editors of *Historiettes de Tallemant des Réaux* (6 vols., 1833–'4), and the founder of the *Revue rétrospective* (20 vols., 1833–'7). From 1838 to 1842 he was a member of the chamber of deputies, and in 1848 he was returned to the constituent and subsequently to the legislative assembly. Early in 1852 he was placed in charge of the catalogue of the national library, of which he published many volumes (1855 *et seq.*), and he was director general of the library from 1858 to 1874. He edited the works of Molière (8 vols., 1823–'4) and Boufflers (2 vols., 1827), and the literary correspondence of Grimm and Diderot (15 vols., 1829–'30), and wrote biographies of Molière (1825) and Corneille (1829; new ed., 1857).

**TASCHEREAU, Elzéar Alexandre,** a Canadian archbishop, born in Quebec in 1818. He studied in the seminary of Quebec, was ordained priest in 1842, and became successively professor of mental philosophy there, director of studies, and superior. In 1856 he received in Rome the degree of doctor in canon law, and was appointed to teach that science in the Laval university. In 1870 he governed the diocese of Quebec as administrator, after the death of Archbishop Baillargeon, and he was consecrated as his successor, March 19, 1871.

**TASHKEND** (anc. *Shash*), a city of Turkistan, formerly included within the boundaries of Khokan, but now under Russian rule, situated in lat. 43° N., lon. 68° 40′ E., near the junction of two small affluents of the Sir Darya or Jaxartes, 150 m. N. W. of the city of Khokan; pop. estimated at 80,000, mostly Mussulmans. It stands in a fertile plain covered with numerous gardens, amid what is described as literally a forest of fruit trees, is enclosed by a high wall of unburned bricks 16 m. in circuit, and is entered by 12 gates. A great part of the town consists of houses surrounded by gardens and vineyards, the walls of which are so close together that only narrow lanes are left between. The houses are principally built of mud, and are about 11,000 in number. The former residence of the khan consists of a castle defended by walls and ditches; and there are more than 300 mosques, 15 bazaars, and numerous colleges and old temples. The principal manufactures are silk and cotton goods, iron, and gunpowder. Commercially, Tashkend is perhaps the most important city in Russian Turkistan. The chief lines of communication from northern Asia concentrate there, and by means of caravans an extensive trade is carried on with all the neighboring countries, including British India. The attempt of the Russian government, however, to establish a great fair at Tashkend, similar to that held at Nizhni Novgorod, has proved a failure.—Tashkend has been celebrated in central Asia from the earliest times for its wealth and as a commercial emporium. It was assaulted and captured by a Russian force under Gen. Tcherniayeff, in the war with Khokan, in June, 1865, and now with the surrounding territory constitutes a separate administrative district of Russian Turkistan.

**TASMAN, Abel Janssen,** a Dutch navigator, born at Hoorn about 1600, died probably on his second voyage to New Guinea and New Holland. In 1642 he was sent by Van Diemen, governor general of the Dutch East India company, to explore the extent of the continent of New Holland. He set sail from Batavia on Aug. 14, and on Nov. 24 discovered the island to which he gave the name of the governor general (now Tasmania). He subsequently discovered New Zealand, the islands of the Three Kings, and the archipelagos of the Friendly and Feejee islands, and returned to Batavia after a voyage of 10 months. On Jan. 29, 1644, he undertook a second voyage along the coasts of New Guinea and New Holland, the details of which are unknown. He published a narrative of his first voyage, which was reprinted with the voyage of Coreal at Amsterdam in 1722.

**TASMANIA** (formerly Van Diemen's Land), a British colony of Australasia, consisting of the island of the same name and several smaller islands, mostly in Bass strait; area, 26,215 sq. m.; pop. in 1870 (by census), 99,328; estimated, Jan. 1, 1874, 104,217. Capital, Hobart Town. The island of Tasmania is situated 120 m. S. E. of Australia, from which it is separated by Bass strait, between lat. 40° 38′ and 43° 38′ S., and lon. 144° 40′ and 148° 30′ E. It is 240 m. long from N. W. to S. E.; its extreme breadth from N. E. to S. W. is 200 m.; area, 24,330 sq. m. The coasts, which present al-

most every variety of scenery, are indented by numerous bays and inlets, and good anchorage is to be found almost everywhere. The principal harbors are: on the W. coast, Port Davey, which is much frequented by whaling vessels, and Macquarie harbor; on the N. coast, Stanley at Circular Head, Emu bay, Port Frederick, Port Dalrymple, and Waterhouse roads, between Anderson and Ringarooma bays; on the E. coast, George, Oyster, Spring, and Fortescue bays; and on the S. E. coast, Port Arthur, Storm bay, Norfolk bay, D'Entrecasteaux channel, Port Esperance, Muscle bay or Southport, and Recherche bay. There are 55 islands off the coast, all of which belong to Tasmania. The Furneaux group, N. E. of the main island, includes Flinders island (801 sq. m.), Cape Barren island (172 sq. m.), Clarke island (30 sq. m.), Chappell, Hummock, and several smaller islands. Their inhabitants, 242 in number in 1870, many of whom are half-breeds, live mostly by seal fishing. Off the N. W. end of Tasmania are King's island (425 sq. m.), Robbins' island (37 sq. m.), Hunter, Three Hummock, and smaller islands. Off the S. E. coast are Bruny island (140 sq. m.), divided into North and South Bruny, which are connected by a narrow isthmus, Maria island (37 sq. m.), Schouten island (10 sq. m.), and many smaller.—Tasmania is traversed by high mountain chains, full of glens and ravines, and separated by fertile and well watered plains. There are two principal chains, one running parallel with the E. coast, the highest peak of which is Ben Lomond, 5,010 ft., and the other forming an elevated table land in the middle of the island, reaching an elevation of 5,096 ft. in Cradle mountain; from the latter diverge numerous smaller ranges, north, west, and south. In the middle of the table land are several lakes, the largest of which are the Great lake (28,000 acres), Sorell (17,000), St. Clair (10,000), and Arthur, Crescent, and Echo (8,000 to 12,000). The chief rivers on the S. E. coast are the Huon, which flows into D'Entrecasteaux channel; the Derwent, which rises in Lake St. Clair, receives numerous tributaries, and flows into Storm bay; and the Coal, which flows into Pitt water. On the S. W. and W. coast are the Spring, the Davey, the Gordon and King's falling into Macquarie harbor, the Pieman, and the Arthur, all with large tributaries; and on the north the Montague, Duck, Detention, Inglis, Cam, Emu, Blythe, Leven, Gawler, Forth, Mersey, Rubicon, Tamar, Piper, Forrester, Trent, and Ringarooma. The Tamar is a tidal river formed by the junction of the North and South Esk.—The central mountain chain, which is of volcanic formation, is of trap upheaved through sandstone, clay, limestone, and slate. The rocks of the E. and S. W. coasts are basalt, granite, gneiss, and quartz. It is conjectured that the island was once connected with Australia, and that the smaller islands in Bass strait are the peaks of a disrupted mountain chain. Tasmania is rich in minerals. Iron abounds near Hobart Town and on the banks of the Tamar river. Large deposits of tin ore were discovered in 1872 at Mt. Bischoff, and small lodes of copper, lead, and bismuth have been found. Coal abounds at Mt. Nicholas and Douglas river in the northeast, on the Mersey river in the north, at Jerusalem N. of Hobart Town, and at Hamilton in the middle of the island. None of these deposits are worked, but mines of bituminous coal are worked near Port Seymour, and of anthracite coal at Port Arthur, New Town, and Port Serrell. The principal gold mines are at Nine Mile Springs, Mathinna, and Hellyer river. Limestone is abundant, and a fine quality of white freestone is largely exported to Melbourne.—The climate is remarkable for mildness, being subject to extremes neither of heat nor cold. The average temperature of the summer months, December, January, and February, is about 62°; of the autumn months, March, April, and May, 55°; of the winter months, June, July, and August, 47°; and of the spring months, September, October, and November, 54°. The mean annual temperature, as ascertained by 30 years' observation, is about 54°. The mean annual rainfall is 22·71 inches. The atmosphere is remarkably pure, and zymotic diseases are rare. Thunder storms are not common and are seldom violent. Many persons, enervated by the hotter climate of Australia, annually visit Hobart Town for health. —Although much of the interior is mountainous and rugged, there are large tracts of pasture land, and extensive forests, chiefly of the eucalyptus and acacia, affording excellent timber for both cabinet work and ship building. The soil is very fertile, and produces abundantly all the cereals, vegetables, and fruits of temperate climates. Among the fruits cultivated are the peach, plum, apricot, cherry, quince, fig, mulberry, gooseberry, strawberry, raspberry, currant, and grape; also the walnut, filbert, and almond. Large quantities of green and preserved fruits are exported. The live stock in 1873 amounted to 22,334 horses, 106,308 horned cattle, 1,490,738 sheep, 59,628 swine, and 2,201 goats. The indigenous animals are mostly marsupials, like those in Australia, and they exist in such numbers that kangaroo leather and opossum furs are articles of export. There is one unique animal, called the thylacine, Tasmanian wolf, or native tiger, the largest carnivorous animal in Australasia, though no larger than a wolf. Whales, both black and spermaceti, are numerous off the coasts, particularly in Bass strait, and the fishery is prosecuted with much vigor; and seals frequent the shores and the islands in their vicinity. Excellent fish are found in all the bays and rivers, and oysters are very abundant. Salmon have been introduced from England, and are now caught in the Derwent. The industries of Tasmania are not extensive. There are several breweries in Hobart Town,

where ale is made for export to the other colonies, the climate being especially adapted to malting and brewing. There are also tanneries, founderies, soap and candle manufactories, jam-boiling and fruit-preserving establishments, and two manufactories of cloth, tweed, blankets, &c. The value of exports in 1873 was £893,556; of imports, £1,107,167. The exports of wool amounted to 4,243,433 lbs., valued at £314,068; of jams to the value of £98,281; and of hops, £41,015. Other articles of export are bark, butter and cheese, bran and pollard, the cereals, flour, skins and leather, horses, sheep, sperm and black oil, fruits and vegetables, gold (in 1873, £15,309), and ale. The most important ports are Hobart Town and Launceston. Frequent communication by steamships is maintained between them and Sydney and Melbourne. The only completed railway is the Launceston and Western, 45 m. long, connecting Launceston and Deloraine. The line was opened in 1871; in 1872 it was taken by the government. The Mersey and Deloraine railway, to connect Deloraine with the mouth of the Mersey river, had 18 m. completed in 1874. A main line, connecting Launceston with Hobart Town, 120 m. long, will probably be opened in 1876. The principal towns are connected by telegraph, of which 291 m. were open in 1873. A submarine cable, laid in 1869, connects Launceston with Melbourne.—The aborigines of Tasmania resembled physically those of Australia, excepting that their hair was wooly. They were estimated to number 3,000 to 4,000 when the island was colonized, and were inoffensive; but from the abuse of the convict colonists a war of extermination broke out. At its close the remnant of the tribe was transported first to Flinders and then to Maria island, and finally in 1849, when only 36 remained, to the vicinity of Hobart Town, where they were established in comfortable dwellings. In 1870 only one, a woman, survived. In 1848 nearly a third of the inhabitants were or had been convicts; and although since the cessation of transportation the proportion has gradually decreased, the moral effect is still felt. With respect to religion, the principal denominations are represented as follows: church of England, 53,047; Roman Catholic, 22,091; church of Scotland, 6,644; Free church of Scotland, 2,420; Wesleyans, 7,187; Independents, 3,931. The whole number of churches and chapels in the colony is 316. The Anglicans and Roman Catholics have each a bishop. Education is under the management of a council, and a board supervises the distribution of all moneys voted by parliament. In 1873 there were 141 public schools, with 10,803 pupils on the rolls and an average attendance of 7,047; 105 male teachers, 108 female teachers, and 32 pupil teachers. There are four superior schools: Horton college, high school, Hutchins's school, and the church grammar school. The attendance of children at the public schools is compulsory, under a fine of £2, except in cases of private education. In 1870 there were 29,444 persons in the colony who were unable to read. The public press includes two daily newspapers published at Hobart Town, two tri-weekly and a semi-weekly at Launceston, and several weekly and monthly periodicals.—The colony is divided into 18 counties, which are subdivided into parishes. For electoral purposes it is divided into districts, 16 for the election of members of the legislative council, and 32 for members of the house of assembly. The government consists of a governor and executive council appointed by the crown. The governor is assisted by a cabinet consisting of four official members, colonial secretary, colonial treasurer, attorney general, and minister of land and works, and sometimes a premier *ex officio*. The legislative power is vested in a parliament of two houses, the legislative council and the house of assembly. The legislative council is composed of 16 members elected for six years, the house of assembly of 32 members elected for five years. The judiciary consists of a chief justice, a puisne judge, and minor justices. The revenue is derived from customs, railway receipts, land sales, and miscellaneous taxes. The general revenue for 1875 was estimated at £295,317, and the expenditure at £311,206. The debt of the colony at the end of 1873 was £1,477,600, incurred mostly for the following purposes: public works, £938,528; immigration, £200,000; commute state aid to religion, £100,000; in payment of an old debt to the imperial government, £30,500; in aid of land fund, £30,000.—Tasmania was discovered in 1642 by the Dutch navigator Abel Janssen Tasman, who believed it to be a part of the mainland of Australia, and who named it Van Diemen's Land after Anthony van Diemen, then governor general of the Dutch East Indies. Its insularity was not established till 1798, when Mr. Bass, a surgeon of the British navy, circumnavigated it. The first settlement was made in 1803 by a detachment of marines and a body of convicts, in charge of Lieut. Bowen, who selected Risdon on the Derwent river as the site for a penal station. In 1804 Col. Collins, who landed with 400 prisoners, changed the site to the opposite side of the river, and named it Hobart Town after Lord Hobart, then secretary of state for the colonies. Van Diemen's Land was erected into an independent colony in 1825. For some years the prosperity of the colony was impaired by the depredations of "bush rangers," or escaped convicts, but they were finally suppressed. In 1853 the transportation of convicts ceased, and on Jan. 4, 1856, on the petition of the legislative council to the home government, the name of the colony was officially changed to Tasmania.

**TASSAERT, Nicolas François Octave**, a French painter, born in Paris, July 26, 1800, died there by his own hand, April 26, 1874. He left the school of fine arts in 1825, and became known

as a distinguished portrait, historical, and genre painter; but long struggles with adversity drove him to suicide. His principal productions include "The Funeral of Dagobert at St. Denis" (for the museum of Versailles), "Death of Correggio," "The Slave Merchant," "Diana at the Bath," and "The Old Musician."

**TASSO, Bernardo,** an Italian poet, born in Bergamo, Nov. 11, 1493, died in Ostiglia in September, 1569. He became in 1531 secretary to the prince of Salerno, and accompanied him in several expeditions of Charles V. In 1539 he settled at Sorrento with his bride, the celebrated Porzia de' Rossi. After her death he fled from the inquisition, became connected with the courts of Urbino and Mantua, and ended his life as governor of Ostiglia. He wrote a heroic poem entitled *L'Amadigi*, founded on the story of Amadis de Gaul, containing 100 cantos. One of the episodes was expanded into a poem called *Floridante*, published after his death by his son. He also wrote sonnets, odes, and lyrics, a "Discourse on Poetry," and "Three Books of Letters."

**TASSO, Torquato,** an Italian poet, son of the preceding, born in Sorrento, March 11, 1544, died in Rome, April 25, 1595. He received his first education at Naples, and studied in Rome, Urbino, Venice, Padua, and Bologna. In 1562 he wrote his charming romantic poem *Rinaldo*, and about the same time began to prepare his epic on the delivery of Jerusalem by Godfrey of Bouillon. In 1565 he went to Ferrara as a gentleman in the suite of Cardinal d'Este, whose brother, the duke Alfonso II., received Tasso with great distinction. His grave and melancholy beauty, eloquence, and varied accomplishments enlisted general admiration, and endeared him to the duke's sisters Lucrezia, the future duchess of Urbino, and Eleonora, who became known as the special object of his adoration. After about a year's residence with the cardinal in Paris, where Charles IX., Catharine de' Medici, and the French poets showed him marked attentions, he became estranged from his patron, and, mainly through the influence of the princesses, was in 1572 formally attached to the court of Ferrara, with a salary but without specific duties. His celebrated pastoral drama *Aminta* was performed in 1573 with great splendor at the court, and afterward at Urbino. In 1575 he completed his great epic poem under the title of *Il Goffredo*, which was afterward changed to *Gerusalemme liberata*. The duke, Eleonora, and Lucrezia (who had separated from her husband) gave him new evidences of their regard, and would hardly permit him to leave them. Yet in November, 1575, he went to Rome to submit his epic to Scipione Gonzaga, and received an invitation to enter the service of the Medici family, which he ultimately declined; but the hostility between the Medici and Estes made him ever afterward believe that the duke had taken umbrage at his negotiation with them, although on his return to Ferrara he was received with the wonted cordiality. He was now living in perpetual fear of his enemies, whose numbers had increased with his fame, and of emissaries of the inquisition, although that tribunal had absolved him from the charge of heresy to which he had long fancied himself liable on account of some passages in the *Gerusalemme*. At length he found his correspondence intercepted, and had a violent altercation with a deceitful friend who had purloined his private papers, with a view, he suspected, of giving the duke evidence of his relations with Eleonora, and he was charged with referring to his love for her in the episode of Sofronia and Olindo in his epic. But the duke expressed no other feeling about him excepting an anxiety for the restoration of his mind, which he regarded, or feigned to regard, as diseased. Even after a murderous assault said to have been committed by Tasso in one of his frantic fits upon Lucrezia's servant, the duke released him after a brief confinement and permitted him to retire to a convent (June, 1577), where he was to remain till the restoration of his health. Tasso, however, fled in July to Sorrento, and reached his sister Cornelia's house in the disguise of a shepherd and in a wretched condition. Having regained his health, he became anxious to return, and at the instance of his friends the cardinals Albano and Gonzaga, the duke permitted him do so on condition of his putting himself under medical treatment. New indignities awaited him at Ferrara (February, 1578), despite the friendly disposition of Eleonora. He failed to recover his manuscripts, and, shunned by everybody, he fled again from city to city, everywhere regarded as a maniac. At the court of Urbino he had a short interval of rest, but his apprehensions of danger drove him to Turin. Here he was befriended by Eleonora's brother the marquis d'Este, and might have lived in peace; but he hastened back to Ferrara in the vain hope that the celebration of the duke's third marriage with a princess of Mantua (early in 1579) would prove auspicious for a reconciliation. He was not permitted to see any member of the ducal family, and the courtiers and lackeys insulted him so grossly that he broke out in vehement denunciations, and was committed to the hospital of Santa Anna. Here he was surrounded by maniacs of the worst description, and treated with a harshness which excited the pity of Montaigne and other visitors. A garbled publication of the *Gerusalemme* in 1580 was followed in 1581 by genuine editions, which had a prodigious circulation, and gave such a prestige to his name that his situation was slightly improved, and many of his admirers availed themselves of the easier access to his cell. The death of Eleonora in 1581, which Lucrezia thought would make the duke relent, had no such effect; and while fortunes were made by the sale of his epic, Tasso lingered in prison. He was not released

until July, 1586, and only after repeated appeals from the most influential quarters and after his health had reached its lowest ebb, and then solely on condition of remaining in charge of Duke William of Mantua, who showed him much kindness. After William's death he made in 1587 ineffectual attempts to better his fortunes in Rome, and in 1588 to recover his patrimony at Naples. For the rest of his life he almost continually travelled from Naples to Rome and from Rome to Naples, enjoying in the latter city his residence at the monastery of Mount Olivet; but he was finally obliged to live in a charitable asylum at Rome until the grand duke of Tuscany came to his rescue and invited him to visit Florence (1590). Here, as everywhere else, he received distinguished though empty honors. In a subsequent journey to Rome, the famous brigand Sciarra refrained from molesting him and his travelling companions, and showed great deference for his genius. In 1593 appeared his *Gerusalemme conquistata*, a remodelled form of his first epic, to which he alone regarded it as superior. It was dedicated to Cardinal Cinzio Aldobrandini, who thereupon induced Pope Clement VIII. to crown Tasso in the capitol. He reached the Vatican on Nov. 10, 1594, but after a relapse of his fever he was taken at his request to the monastery of St. Onofrio, on the Janiculum, where he died before the time assigned for his coronation.—The tribulations of the poet, the peculiar condition of his mind, his relations with the princess Eleonora, and the duke's proceedings against him, have given rise to many conflicting statements, and thrown a pathetic halo over his life and genius. Goethe has made him the hero of a celebrated drama; Hallam regarded him as superior to Virgil in grace, though inferior in vigor; Ranke and other eminent scholars have written on him extensively; Lamartine has called him "the crusader of poetry;" and Friedrich Schlegel places him above Ariosto on account of his melodious versification and picturesque and impassioned delineations of love. The academy della Crusca, however, bitterly contested at the time Tasso's superiority over Ariosto. The most complete of the early genuine editions of the epic appeared at Parma (4to, 1581), and the most correctly printed among the latest editions is that of Padua (3 vols. 24mo, 1827–'8). It has been translated into most Italian dialects and into Latin, repeatedly into English, French, German, Spanish, Portuguese, Polish, and Russian, and in 1875 into modern Greek. The best translation into English is by Edward Fairfax (London, 1600; latest American ed., New York, 1855); and the most recent English version is by Sir J. K. James (2 vols., 1865). The *Gerusalemme* has cast Tasso's other works into the shade, although his *Rime* or lyrical poems are unsurpassed in their descriptions of disappointed love, and the choruses in his otherwise unsuccessful tragedy *Torrismondo* are remarkable for pathetic sweetness. His prose dialogues, moral treatises, and other minor works are also entitled to more attention than they have received. The most complete edition of his works is by Rosini (33 vols., Pisa, 1821–'32). A good select edition appeared at Milan (5 vols., 1823–'5). His principal biographers in Italian are his friend Manso (Naples, 1619) and Serassi, whose work is the most complete (Rome, 1785; new ed., Florence, 1858); and in English, Black (2 vols. 4to, Edinburgh, 1810) and R. Milman (2 vols., London, 1850). See also "Conjectures and Researches concerning the Love, Madness, and Imprisonment of Torquato Tasso," by Richard Henry Wilde (2 vols. 12mo, New York, 1842); *Sulla causa finora ignota delle sventure di Tasso*, by Capponi (2 vols., Florence, 1840–'46); a complete chronological edition of his correspondence, by C. Guasti (5 vols., 1852–'5); and *Degli amore e della prigione di Tasso*, by L. Cibrario (Turin, 1862).

**TASTE**, the sense by which we distinguish the sapid properties of bodies, through the sensory apparatus in the mouth. Though the tongue takes the principal cognizance of gustatory sensations, the soft palate and its arches and the fauces share in this office. The nerves of taste are the lingual branch of the trifacial or fifth pair of cerebral nerves, distributed to the mucous membrane of the anterior two thirds of the tongue, and the glosso-pharyngeal nerve, which supplies the base of the tongue, the soft palate, pillars of the fauces, and upper part of the pharynx. The glosso-pharyngeal nerve is also regarded as the channel by which disagreeable impressions producing nausea and vomiting are propagated to the medulla oblongata. The exact seat of the sense of taste has been determined by placing in contact with various parts of the mucous membrane small sponges moistened with some sweet or bitter fluid, like a solution of sugar or quinine. It is thus found that the power of perceiving savors resides in the whole upper surface (*dorsum*) of the tongue, its point and edges, the soft palate, the fauces, and part of the pharynx. The most acute sensibility to taste is found in the base, tip, and edges of the tongue, while it is less marked in the middle of its upper surface, and almost or entirely wanting in its inferior surface. These parts are also supplied with general sensibility by the same nerves which communicate to them the sense of taste; and in the tip and edges of the tongue the general sensibility is even unusually acute, as compared with the external integument or other mucous membranes. (See TONGUE.)—Owing to the existence of these two kinds of sensibility in the organs of taste, we must distinguish between the different impressions produced upon them by foreign substances. The sapid qualities, properly speaking, which we distinguish by the sense of taste alone, are such as we designate by the terms sweet, sour, alkaline, salt, bitter, &c., besides

various compound savors, like those of cooked meats, vegetables, and fruit. But other physical qualities are often mingled with these, which are of a different character, and are perceived by the general sensibility of the mucous membrane, here developed to an unusual degree. Thus, what is called a viscid, watery, or oleaginous taste is simply a certain modification in consistency of the substance under examination. An oil may have a well marked taste; but this is in consequence of its partial rancidity, or of its containing other impurities or sapid ingredients. An oil which is perfectly pure and fresh is almost or entirely destitute of taste, and conveys to the mucous membrane of the mouth only the sense of its oleaginous consistency. Other substances have an irritating or pungent quality, like alcohol, red pepper, and mustard; and this pungency is also perceived by the general sensibility of the mucous membrane. Most of the condiments in ordinary use produce their effect principally by means of their pungency, mingled with a small proportion of true sapid qualities. Many articles of food also have their taste modified or heightened by the presence of volatile ingredients perceived by the sense of smell; and this mixture of sapid and odoriferous qualities gives to the substances in question the properties which we know as their flavors. In this way are produced the flavors of wines, of tea and coffee, of cooked meats, &c. How much of the effect produced by these substances upon the senses is due to their odoriferous qualities, may be ascertained by holding the nose while swallowing them, so as to prevent the passage of air through the nasal passages.—An essential condition of the sense of taste is, that the sapid substance should be in a state of solution. In the solid form a substance even of well marked sapid quality, like crystallized sugar, produces no effect upon the taste, and is perceived when applied to the tongue only as the physical contact of a foreign body. It is only when it is presented in the liquid form, or is gradually dissolved in the fluids of the mouth, that it impresses the nerves of taste, and its sapid qualities are accordingly perceived. This is probably because sapid substances excite the sense of taste only by being actually absorbed by the mucous membrane, and thus coming in contact with the extremities of the gustatory nerves. This absorption requires time for its accomplishment, and especially requires that the substance, to be taken up by the mucous membrane, should be in a proper condition of fluidity. It is also on this account that a free secretion of saliva is so essential an aid to the sense of taste. When the internal surface of the mouth is in a dry condition, the savor of the food is imperfectly perceived. The salivary fluids, being themselves partly composed of organic materials, are especially adapted for rapid absorption, and, as they penetrate the mass of the food undergoing mastication, they become impregnated with its sapid ingredients, and cause them to penetrate readily the substance of the mucous membrane. The sense of taste is also materially aided by the movements in mastication, and particularly by those of the tongue; since a combination of movement and pressure is always favorable to the absorption of fluids by the animal membranes. The full effect of sapid substances is not obtained until the moment of actual deglutition. It is only after mastication is complete, and the food is actually in the involuntary grasp of the fauces and pharynx, to be swallowed into the stomach, that all parts of the gustatory mucous membrane are brought in contact with it at once, and their sensibility heightened by the simultaneous contraction of the muscles of deglutition.

**TATE**, a N. W. county of Mississippi, formed in 1873 from De Soto and Marshall counties; area, 406 sq. m.; pop. about 12,000. It is drained by Coldwater river, and traversed by the Mississippi and Tennessee railroad. The surface is undulating, and the soil fertile. The chief crops are wheat, Indian corn, sweet potatoes, and cotton. Capital, Senatobia.

**TATE, Nahum**, an English poet, born in Dublin in 1652, died in Southwark, Aug. 12, 1715. He went to London, succeeded Shadwell in 1692 as poet laureate, and died in the precincts of the mint, a privileged place for debtors. He was associated with Dryden in the authorship of "Absalom and Achitophel," the second part of which is mostly his composition. He wrote "Memorials for the Learned, collected out of eminent Authors in History" (1686); "Miscellanea Sacra, or Poems on Divine and Moral Subjects" (1698); and "Panacea, a Poem on Tea" (1700). He also produced an alteration of "King Lear" from Shakespeare, which long held the stage to the exclusion of the original. But he is chiefly remembered by his version of the Psalms, made in conjunction with Brady, which is still retained in the "Book of Common Prayer." It was first published under the title of an "Essay of a New Version of the Psalms of David, consisting of the first Twenty, by N. Brady and N. Tate" (8vo, 1695). This was succeeded by "The Book of Psalms, a New Version in Metre, fitted to the Tunes used in the Churches, by N. Tate and N. Brady" (1696), and a "Supplement of Church Hymns" (1700).

**TATIAN** (Tatianus), an ecclesiastical writer of the 2d century, the time and place of whose birth and death are uncertain, though he calls himself an Assyrian. He had received the education of a Greek, and been a teacher in the pagan schools before he went to Rome, where he practised as a teacher of eloquence, became the associate of Justin Martyr, and was converted to Christianity. After the death of Justin (about 165), he seems to have returned to the East, and adopted views resembling those of the Gnostic Marcion on the dual principle of good and evil, and on the essential depravity of matter. He became the founder

of a sect known as Tatianists, forbade marriage, animal food, and wine, substituted water for wine in the eucharist, and required the giving up of worldly goods as the evidence of Christian sanctity. His "Discourse to the Greeks" (Πρὸς Ἕλληνας), written while he was still orthodox, has passed through many editions, the earliest being that of Zürich in 1546, and the best that of Oxford (8vo, 1700). The account of Tatian and his opinions is best given by Le Nourry in Worth's edition of his works; by the Benedictine Ceillier, in vol. ii. of his *Auteurs sacrés et ecclésiastiques;* and by Daniel in *Tatian der Apologet* (Halle, 1837).

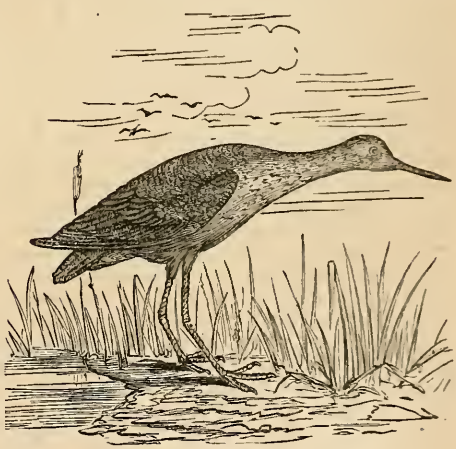
**TATIUS, Achilles.** See ACHILLES TATIUS.

**TATKELEFF, Vogisny.** See p. 905.

**TATNALL,** a S. E. county of Georgia, bounded S. by the Altamaha and N. E. by the Cannouchee, and intersected by the Great Ohoopee river; area, about 1,200 sq. m.; pop. in 1870, 4,860, of whom 1,280 were colored. The surface is level, and the soil sandy and mostly poor. The chief productions in 1870 were 74,684 bushels of Indian corn, 28,117 of oats, 25,386 of sweet potatoes, 314 bales of cotton, 23,834 lbs. of wool, and 120,012 of rice. There were 699 horses, 700 mules and asses, 4,567 milch cows, 15,138 other cattle, 12,030 sheep, and 13,420 swine. Capital, Reidsville.

**TATTA,** a town of British India, in Sinde, on the W. bank of the Indus a few miles above the head of the delta, 48 m. S. S. W. of Hydrabad; pop. about 10,000. It stands on ground slightly elevated by ruins, which are exceedingly abundant in the vicinity, and include an old cemetery said to contain 1,000,000 tombs. The town is much decayed. During the season when the river overflows its banks it is almost completely surrounded by water. There are some manufactures of cotton and silk goods, but the trade is not very extensive. Tatta is supposed to be the ancient Pattala. The Portuguese plundered it in 1555, and the British established a factory there in 1758.

**TATTLER,** the proper name of the wading birds of the snipe family, of the division *totaneæ*, as distinguished from the *tringeæ* or sandpipers; they are often called sandpipers, in England gambets, and in France *chevaliers* or *totanes.* The bill is slender, nearly straight, about as long as the tarsus, pointed, not grooved for the terminal fourth, gape extending beyond the culmen, terminal half hard and horny, and base covered with a soft skin; wings long; legs and neck elongated; toes connected anteriorly by membrane; tail almost always strongly barred. They are genuine waders, frequenting the water's edge, picking up insects, mollusks, &c.; they are swift fliers and runners, and some species take readily to the water; they perform migrations of considerable extent, going north to breed in spring, and returning through the temperate regions in early autumn, at which time the flesh is fat, juicy, and much esteemed. The French name is derived from the body being mounted on long legs, and appearing as if on horseback. The nest is on the ground, usually near water, and the young quit it as soon as hatched; in the breeding season they keep in pairs, and the families remain together until spring.—The tell-tale tattler or greater yellow-legs (*gambetta melanoleuca*, Bonap.) is about 14 in. long, 25 in. in alar extent, with the bill $2\frac{1}{4}$ in.; wings long, first quill the longest; tail short; legs yellow and long; hind toe small. Above it is cinereous of various shades, with lines, spots, and edgings of dull white; lower back brownish black; rump and upper tail coverts white with more or less perfect brownish bands; white below, with brownish stripes on neck and bars of spots on breast; quills brownish black; tail white, with brownish black bands. This bird, sometimes called stone snipe, is found throughout temperate North America and Mexico, preferring large soft marshes and the vicinity of fresh



Tell-Tale Tattler (Gambetta melanoleuca).

water; it lives with other waders and the smaller ducks; the common name is derived from the habit of uttering its shrill whistle of four loud and rapidly repeated notes at the least sign of danger, giving the alarm to all the ducks and other game birds in the neighborhood; its notes are easily imitated, calling the bird within gun-shot; the flesh in autumn is excellent eating; the eggs are four, $2\frac{1}{4}$ by $1\frac{1}{2}$ in., pale greenish yellow, with brown and purplish gray blotches. The common yellow-legs and the willet will be noticed under those titles.—The spotted tattler or peet-weet (*tringoides macularius*, Gray) is $7\frac{1}{2}$ to 8 in. long, 13 in. in alar extent, with the bill 1 in., and the tarsus rather less; the bill has both mandibles grooved and is tapering; lower third of tibiæ naked; tail much rounded; outer toe webbed to first joint. It is brownish olive-green above, with bronzed lustre and lines and spots of brownish black; line over eyes and

under parts white, the latter with circular brownish black spots; primaries, secondaries, and outer tail feathers tipped with white, the last with irregular brownish black bars. It is found over temperate North America, in Central America in winter, and also in Europe; it is one of the most common marsh birds of New England, arriving from the south about the beginning of May; it is often called "teeter" from the jerking of its tail up and down; it does not associate with other species, nor form large flocks; it alights on branches overhanging the water, and on fences and walls; the flesh is delicious in autumn; the eggs are 1¼ by 1 in., grayish yellow with deep brown blotches; both sexes incubate.

**TAUCHNITZ. I. Karl Christoph Traugott**, a German publisher, born at Grosspardau, near Grimma, Oct. 29, 1761, died in Leipsic, Jan. 14, 1836. He learned the printer's trade at Leipsic, and worked in the celebrated printing house of Unger in Berlin. In 1792 he entered the house of Sommer in Leipsic, and in 1796 established in that city the house long known by his name. He began with a small printing house, but in 1798 opened a bookstore in connection with it, and in 1800 a type foundery. In 1809 he published the first volumes of a series of Greek and Latin classics, which, from their accuracy, cheapness, and convenient size, became very popular. He also published some very perfect editions of classical authors in folio. In 1816 he established the first stereotype foundery in Germany; and he was the first to stereotype music. His edition of Mozart's *Don Giovanni* had a wide popularity. He also printed stereotype editions of oriental works, including two of the Hebrew Bible, and an edition of the Koran. **II. Karl Christian Philipp**, son of the preceding, born in Leipsic, March 4, 1798. He enlarged his father's business, and carried it on with success until he retired in 1865. Besides many celebrated and important philological publications, he completed in 1840 Fürst's edition of the Hebrew concordance. **III. Christian Bernhard**, baron, a German publisher, cousin of the preceding, born Aug. 25, 1816. He founded in Leipsic in 1837 a publishing house, which has become celebrated by the issue of a collection of English works, well known as the "Tauchnitz editions," of which more than 1,000 volumes had been published in 1868, of more than 120 English authors; a copyright for the continent being secured for the more recent works. In 1866 he began the publication of a series of German authors for the use of English-speaking people. In 1860 the title of baron was conferred upon him by the duke of Saxe-Coburg-Gotha, and his title was recognized by the king of Saxony in 1861.

**TAULER, Johann**, a German mystic, born probably in Strasburg in 1290, died there, June 16, 1361. At the age of 18 he renounced a fortune to enter the Dominican cloister. After studying the scholastic theology in Paris he returned to Strasburg, and came under the influence of Master Eckhart. He became one of the so-called "friends of God," an unorganized brotherhood, including priests, nobles, and burghers in all the large cities, who represented the height of mysticism, denied the special prerogative of the clergy except in the celebration of the sacraments, and dwelt upon worship in the heart and life. He preached in Strasburg, Cologne, and Basel, where Henry of Nördlingen had resumed his forbidden functions. Amid the ravages of the black death (1348–'9), he bestowed the consolations of religion on the people, preaching in German mingled with Latin. He wrote in German a treatise on "Following the Lowly Life of Christ" (Frankfort, 1621), addressed a remonstrance to the clergy against leaving the dying unattended and unabsolved, and denounced ecclesiastical abuses. Having been summoned by the emperor Charles IV., when at Strasburg in 1348, to render an account of his faith, he disappeared from the city, but returned there shortly before his death. The best of the early editions of his sermons are those of Leipsic (1498), Basel (1521–'2), Halberstadt (1523), and Cologne (1543). There is a modern German translation by Schlosser of his sermons (3 vols., Frankfort, 1826; 2d ed., 1864), and of his *Nachfolgung des armen Lebens Christi* (1833). The hymns attributed to him are of doubtful authenticity.—See Schmidt, *Johannes Tauler von Strasburg* (Hamburg, 1841), and Miss Winkworth, "Life and Times of Tauler," with 25 of his sermons translated from the German (1857).

**TAUNTON**, a city and one of the shire towns of Bristol co., Massachusetts, at the head of navigation on Taunton river, 24 m. from Narragansett bay, 17 m. E. of Providence, R. I., and 32 m. S. of Boston; pop. in 1850, 10,441; in 1860, 15,376; in 1870, 18,629, of whom 4,605 were foreigners; in 1875, 20,429. In shape it is an irregular polygon, having an extreme length N. W. and S. E. of 11 m. and an average width of 6 m. The surface is generally level; half of the land is wooded with forests of pine, oak, beech, and cedar, and there are five ponds of considerable size. It is traversed by the Taunton river and two principal branches, the Canoe and Rumford, which furnish power for many mills and factories. Navigation is impeded by ice but a small part of the winter. The city communicates by rail with Boston, Providence, Fall River, Newport, New Bedford, Cape Cod, and various other points, and has a line of street cars. There are several villages within the city limits. The streets of the central village are well laid out, lighted by gas, and adorned by shade trees of various kinds. The "green" is a well shaded public ground. There are many elegant residences, some of great cost, to which are attached gardens and conservatories. The principal public buildings are the court house, city hall, hotels, school houses, and churches. The

state hospital for the insane occupies a conspicuous site, with grounds of more than 140 acres, and accommodates over 400 patients. Taunton has from the beginning been noted for its manufacture of brick and iron, the latter being at present the leading business, and employing a capital of about $2,000,000. There are two locomotive works, two tack and nail factories, several founderies and machine shops, &c. In copper manufacture a capital of about $900,000 is invested. The Taunton copper company, the oldest and largest in the United States, has been incorporated nearly 50 years. Its products are copper, sheet zinc, and yellow metal sheathing. Among other establishments are two manufactories of silver-plated and britannia ware, four of stove linings and fire brick, two of crucibles, five cotton factories, a flannel factory, a carriage factory, &c. There are three national banks, with an aggregate capital of $1,300,000, and two savings banks, with deposits to the amount of $4,500,000. The coasting trade is important. Taunton and Taunton river are also proverbial for their herring fisheries, the privileges of which are still annually sold, though few of the inhabitants now pursue this branch of industry. Large quantities of shad and alewives are taken from the river in April and May.—The city is governed by a mayor, eight aldermen (one from each ward), and 24 common councilmen. The taxable value of property in 1874 was $18,326,-228; city debt, $275,600. The public schools comprise the following grades: high, 1; grammar, 12; intermediate and primary, 31; ungraded schools, 15. The number of pupils enrolled in 1874 was 3,654; average attendance, 2,522; total expenditure for support of schools, $42,759 58. There are two private schools, an incorporated academy, a public library of 13,000 volumes, and a daily and two weekly newspapers. The principal charitable institutions are the insane asylum, the city almshouse, and a home for aged and infirm women. There are 19 churches, viz.: 2 Baptist, 3 Congregational, 2 Episcopal, 1 Free-Will Baptist, 4 Methodist, 2 Roman Catholic, 3 Unitarian, 1 Universalist, and 1 Union.—Taunton, of which the Indian name was Cohannet, was settled in 1638 by a company from Taunton in England, from whom a large proportion of the present natives of the town are descended. It became a city in 1864. One of the chief promoters of its settlement was Miss Elizabeth Pool, to whom a monument has been erected in the cemetery. In King Philip's war the town was protected from harm by the king's friendship for Thomas Leonard. Here was Philip's favorite hunting ground.

**TAUNTON**, a town of Somersetshire, England, on the Tone, 133 m. W. S. W. of London; pop. in 1871, 15,466. It has an old castle, several places of worship, including the church of St. Mary Magdalen with a fine renovated tower, and various charitable and educational institutions. Among the latter is a college established in 1868 by the Congregationalists at Fairwater, outside of the town. The wool manufactories established in the 14th century have long since declined, and gloves are now the staple industry. In 1645 it was held by Blake for the parliament, and sustained a protracted siege by 10,000 royalists.

**TAURIDA**, a S. government of European Russia, bordering on the governments of Kherson and Yekaterinoslav, the sea of Azov, and the Black sea; area, 24,537 sq. m.; pop. in 1870, 704,997, a large part Tartars. The government includes the Crimea (the Tauris of the ancients, whence the name Taurida), which comprises nearly one third of the area and population, and contains the capital Simferopol, and the principal port and naval station Sebastopol. (See Crimea.) The N. part is a dry elevated country, with a sandy soil impregnated with salt, and without trees, but with some rich valleys that produce luxuriant herbage. Agriculture is little attended to, and the country is chiefly devoted to rearing cattle. A few small streams flow into the sea of Azov, but the only river of importance is the Dnieper on the N. W. frontier. Numerous tongues of land formed by alluvial deposits project from the S. coast, the most extensive of which lies S. of the estuary of the Dnieper, and was anciently called Achilleos Dromos, or Race Course of Achilles. Salt, saltpetre, and naphtha are abundant, and marble is quarried.

**TAUROMENIUM**, an ancient Greek city on the E. coast of Sicily, about half way between Messana and Catana, founded on the hill of Taurus, overlooking the sea, after the destruction of Naxos, 3 m. to the south, by Dionysius the Elder of Syracuse, in 403 B. C. In 394 Dionysius besieged it unsuccessfully for a long time, but it fell into his hands in 392. In 358 Andromachus, the father of the historian Timæus, is said to have collected all the exiled Naxians, and established them at Tauromenium. In 344 Timoleon landed here, but left Andromachus in possession. Subsequently it fell into the hands of Hiero, king of Syracuse. During the servile war in Sicily (134–132) it was desperately defended by the insurgent slaves. It was one of the last places taken from the Greek emperors by the Saracens (906), who destroyed it. The modern village of Taormina occupies its site.

**TAURUS**, a range of mountains in Asia Minor, forming in the main the watershed between the waters flowing into the Mediterranean and those flowing into the Black sea. It consists of two principal chains, the Taurus proper, in the south of the peninsula, and its northeasterly continuation, the Anti-Taurus. With its ramifications in the north, which by former geographers were generally designated as the Anti-Taurus, the range forms three sides of the broad plateau of central and eastern Asia Minor. The commencement of the Taurus proper on the west is a disputed point. Its principal divisions are the Lycian and the Ci-

lician Taurus. It follows closely the sinuosities of the coast, leaving but a narrow margin between; the northern slopes are less abrupt than the southern. Snow-capped peaks are numerous, and fine forests cover the sides of the chain. In the ancient province of Lycia the summits Takhtali Dagh and Ak Dagh are respectively 7,800 and 9,800 ft. high. Gok Dagh, on the confines of ancient Pisidia, Isauria, and Cilicia, is of about equal height with Ak Dagh, while the highest summit of Bulghar Dagh, further east, reaches an elevation of about 11,400 ft. The Ala Dagh connects Bulghar Dagh with the Anti-Taurus, which extends from the W. branch of the Sihun (anc. *Sarus*), through Cappadocia, to the vicinity of the upper Euphrates and the Armenian mountains. The Arjish Dagh (anc. *Argæus*, in Cappadocia), the highest peak of Asia Minor (13,100 ft.), though isolated, is generally reckoned as belonging to the Anti-Taurus. On the whole, however, this chain is less high than the Taurus proper. The Amanus range, E. of the river Sihun (anc. *Pyramus*), connects the Anti-Taurus with the mountain system of Syria. The main pass between the latter country and Asia Minor, called by the ancients the Cilician Gates, is formed by the valley of the upper Cydnus (now Tersus), in the Cilician Taurus, N. W. of Adana.

**TAUSIG, Karl**, a German pianist, born near Warsaw, Nov. 4, 1841, died in Leipsic, July 17, 1871. He studied under his father and Liszt, after whom he ranked as the first pianist in Europe. In 1861–'2 he brought out at Vienna works of Liszt, Wagner, and Berlioz in such a manner as to gain for himself a great reputation as an orchestral director. In 1865 he went to Berlin and was made court pianist, and became the head of the institution for piano virtuosos. He played without notes nearly every great composition from the time of Bach to Liszt.

**TAUTOG.** See BLACKFISH.

**TAVASTEHUUS. I.** A S. W. län or government of Finland, Russia; area, 8,324 sq. m.; pop. in 1872, 193,477, all Lutherans. It is mountainous, and has many lakes. Corn, hemp, flax, and cattle are produced. **II.** A town, capital of the län, 85 m. N. E. of Abo; pop. in 1867, 3,150. The first Finnish railway was opened in 1862 hence to Helsingfors.

**TAVERNIER, Jean Baptiste**, a French traveller, born in Paris in 1605, died in Copenhagen in 1689. He early explored many countries, served occasionally as a soldier, and made six journeys to western Asia and to India, mostly on foot. His father-in-law, a jeweller, having taught him the art of valuing precious stones, he acquired a fortune, was ennobled by Louis XIV. for promoting French trade in India, and bought the barony of Aubonne near the lake of Geneva; but he was ruined by his nephew, and in 1687 fled to Berlin to escape persecutions as a Protestant. There he became director of an East Indian company, and soon undertook a seventh journey, which was interrupted by his fatal illness in Denmark. Louis XIV. bought of him millions of francs worth of diamonds. Under his direction Chappuzeau edited *Les six voyages de J. B. Tavernier* (2 vols., 1676–'7), and La Chapelle a 3d volume in 1679. The latter also reëdited in 1675 *Nouvelle relation de l'intérieur du sérail du grand seigneur*, *Une histoire du Japon*, and *Mémoire sur la conduite des Hollandais*. The first named work has been frequently reprinted and translated (English, 2 vols. folio, 1678–'84).

**TAXES**, the contributions levied by a government upon persons and property, for the use of the government. As a revenue for the use of the state is absolutely essential to the existence of any orderly government, it is reasonable to infer that taxes were levied preceding the earliest of which historical records remain. But in the early ages rulers had other means of supplying their wants without resort to regular levies. One of these might be property of which the state or its ruler had the ownership, the rents or other returns from which rendered taxes unnecessary. In early periods, also, fines and confiscations or compensations for crime constituted an important source of revenue. The early taxes were most severe where the religious worship was supported by this means. Among the Hebrews, in the time of the theocracy, there was a capitation tax of a half shekel (about 30 cts.) payable by every male in the nation (according to some the regular payment of this was of later origin); a tribute of the first fruits, and of the first born of their domestic animals, which might be commuted for money at a fixed rate; a redemption tax for the first born male of the family; and a first and second tithe for the support of the Levites and of the service of the tabernacle, and every third year a third tithe (according to some an application of the second tithe) for the benefit of the poor, and so in some sense a poor rate. After they adopted the regal form of government, the taxes were greatly increased. Solomon collected a large revenue; and the stoning to death of Adoram, "who was over the tribute," and the secession of the ten tribes at the commencement of the reign of his son and successor, indicate how oppressive had been the taxation.—In the Athenian republic there were no direct taxes, either on personal or real estate; the sources of revenue were the lands of the republic, fines and confiscations, the royalty of $\frac{1}{24}$ of the products of the mines, a capitation tax on freedmen and foreigners resident in the republic, customs duties on foreign commodities and merchandise, on which a tariff of 2 per cent. was levied, some excise duties, licenses of markets and houses of prostitution, and tribute paid by other cities and islands. The imposts, licenses, &c., were generally farmed to companies, which gave security for their prompt payment. In times of war, extraordinary contributions were levied

on wealthy citizens, or an appeal was made to their patriotism. The common people, so far from paying any tax except the duty on the goods they purchased, received from the state large appropriations for public games and spectacles. In Rome, under the republic, the spoils of conquered nations and the annual tribute exacted from them defrayed the greater part of the expenses of the state; but under the empire it was found necessary to resort to numerous devices of taxation, portions of the territorial revenues were sequestrated, capitation taxes levied, tolls, taxes on corn, and legacy and hereditary duties collected, heavy sums exacted for the privilege of Roman citizenship, &c. During a large part of the middle ages, under the feudal institutions, there was no system of taxation. The kings were maintained by the products of their land, and in case of war their vassals, the barons and knights, were under obligation to furnish their quota of men-at-arms equipped and provisioned without expense to the monarch; and this military service was performed by their tenants by way of rental for the lands they cultivated. The first approach to modern systems was made during the middle ages by the republic of Venice, which levied taxes on the lands of the republic, and also in the form of duties on manufactures and imports; these duties, which brought in a large revenue, were imposed on the necessaries as well as the luxuries of life. In France, prior to the revolution, there was a serious obstacle to any equitable system of taxation in the fact that the nobility and clergy, the privileged classes as they were termed, were exempted from its burdens. In England the finances for centuries were badly managed; there was little encouragement to industry, and the taxes, whether direct or indirect, were insufficient for the expenses of the government. The privileged classes were exempted as in France. Resort was often had to the sale of monopolies, and to forced loans, contributions, and confiscations. In most of the other countries of Europe no taxes were levied on the clergy or the nobles. In the countries of western Asia, the government of provinces with the right of taxation was bestowed on favorites, or sold to the man who would pay highest for it; and as the duration of the government of these rulers was short, they practised the most cruel extortion, completely annihilating industry, and often transforming countries once prosperous and populous into desert wastes.—Taxes are either direct or indirect. The former are those which are levied upon the persons, property, business, income, &c., of those who are to pay them; the latter are levied on commodities in the hands of manufacturers and dealers, and will be paid ultimately by consumers as a part of the price of the commodity. Presumptively the former are paid by the persons taxed, while as to the latter the persons who make payment to the government only advance to it the taxes, expecting to reimburse the amount in their sales and thus transfer the tax to the purchasers. They constitute therefore as to these taxes the collectors for the government, collecting with ease and convenience from the whole body of consumers a tax which it would be difficult and expensive, perhaps impossible, for the government to collect from the several consumers after the articles taxed have passed into their hands. But though direct taxes presumptively fall upon the persons taxed, a portion of the burden is usually transferred to others, and is diffused through the community in a manner that renders it impossible to indicate the precise extent. A direct tax on lands is paid by the land owner; but if the revenues of the state were principally collected from this source, the necessary result would be such an increase in the price of everything which the land produces as would transfer to consumers a large proportion of the tax, and thus have the effect of an indirect tax upon them. A like result must follow the taxation of professional incomes, unless the incomes of other callings are taxed proportionably, so as to equalize the burden by the tax law itself, instead of leaving it to be equalized by the increase in price of whatever those who pay the tax have to sell, as compared with the price of what is sold by those who are not taxed. A process of equalization of this nature must always be going on when one class of property or occupation is taxed and another exempted. —The true principles of taxation were little understood until the time of Adam Smith, and even now are in many particulars the subject of earnest controversy. That writer laid down maxims of taxation as follows: "1. The subjects of every state ought to contribute toward the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. 2. The tax which each individual is bound to pay ought to be certain, and not arbitrary; the time of payment, the manner of payment, and the quantity to be paid, ought all to be clear and plain to the contributor and to every other person. 3. Every tax ought to be levied at the time and in the manner in which it is most likely to be convenient for the contributor to pay it. 4. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state." Prof. Amasa Walker, in his "Science of Wealth," adds to these the following, which he justly says has been adopted in every country having any considerable taxation: "5. The heaviest taxes should be imposed on those commodities the consumption of which is especially prejudicial to the interests of the people." The first of these maxims has met with little or no recognition except in recent times. It has already been said that until recently,

even in the most civilized countries, precisely those classes who enjoyed the largest revenue, and presumptively were most able to contribute to the support of government, were exempted altogether. The modern idea not only accepts this first maxim, but it goes somewhat further in a direction opposite to the practice of former times, and holds that revenue which is only sufficient for the support of the person and his family should be regarded as not subject to taxation at all, but the whole burden should be levied upon the large revenues. Full effect is seldom given to this idea, but its recognition is seen in the exemption of small incomes when an income tax is laid, and in the exemption of household furniture, tools of trade, &c., when property is taxed by value. While this first maxim is true in a general sense, there are many exceptions to be made to it, and no tax system ever professes to be framed in strict accordance with it. The land owner who voluntarily allows his lands to lie idle and produce no returns, and thus avoids contributing to the common benefit of society, has no claim to exemption; and as his property is meanwhile protected by the government, it is only reasonable that he should make due return for this protection. A man possessed of large means may have them invested in a large establishment, fine grounds, elegant collections of art, &c., which a moderate income enables him to support; while another whose whole capital is kept in productive employment may realize no greater income from his comparatively small means, supplemented by his own labor. Obviously in such cases income could not be a proper standard of taxation as between the two. To render the maxim just in all cases, other than pecuniary returns must be had in view, and the standard of taxation must embrace something besides income. In modern times complicated systems have generally been established in which taxes have been laid on expenditure as well as on income, and to these have been added taxes on the value of property, the purpose being to levy a diversity of taxes which, as they work together, will be likely to result in distributing the burdens of government more equally and justly than any single tax could possibly do. The second maxim is one that should admit of no exception when direct taxes are laid; but when taxes are indirect, one of their chief advantages is supposed to be that they are paid by the people without their being aware at the time that they are paying taxes at all, or at least without reflection on their part that what they pay as price includes a tax. The third maxim is sometimes had in view in the imposition of taxes in kind, but it must be very rare indeed that this method of obtaining a revenue can be either convenient to the people or economical to the government. Only when extraordinary circumstances preclude a ready exchange of the products of the country for money, such as for a time existed while the southern states of the Union were in insurrection against the government, could taxes in kind be preferable either to the tax payers or to the government. The exchange of property for money is always better done by individuals than by the government, and the government consults the interests of the people by making taxes payable at the season of the year when the harvests have generally been gathered, and when it is presumed the tax payers can most conveniently meet the demand. The fourth maxim is often violated by large and needless accumulations in the public treasury, which are impolitic for the further reason that they tend to extravagance and corruption and invite peculation. One important measure which governments adopt has express reference to this maxim, viz., the warehousing system, under which the importer, instead of being compelled to pay the customs duties on the arrival of the goods, and to charge his customers with the consequent loss of interest until sales are made, is permitted to leave them in store, and to pay the duties when the goods are withdrawn for sale. Mr. Walker's supplementary maxim is had in view in all well regulated governments. Spirituous and fermented liquors and tobacco are usually made to pay heavy taxes, while breadstuffs are exempt, or only taxed as a part of the general property of the country by value; and at the same time perhaps license taxes will be imposed upon dealers in spirits and tobacco, and also upon the keepers of billiard tables and places of amusement.—The taxes which have been laid at different times have been almost infinite in variety, depending sometimes mainly on considerations of policy, while at others the necessities of government have compelled it to make use of every available means of extracting money from the people. One of the earliest taxes was perhaps a capitation tax, but this can seldom be reasonably fair or equal, because it can take no account of the differences in condition, resources, or income of the persons taxed. The land tax was also an early device, and the feudal services easily slid into a burden of this character. A land tax as a part of a system of taxes may be a just tax, and by itself may not be so unequal or unjust as would at first be supposed. Land is the most available resource for direct taxation, and in this country land is found in the hands of so large a portion of the people that the states are enabled to raise the greater part of their revenues from this source without exciting any general feeling of discontent. Land taxes may be measured by area, which, except in the case of assessments for some local purposes, must always be unequal, or they may be measured by rents or by value. A house tax is common in other countries, and was formerly measured by windows or hearths; but as the adoption of either standard tended to diminish the number of the convenience which was the measure of the tax, the rent or rental value is generally

substituted. The income tax, however just in theory, has always proved unequal from the impossibility of obtaining accurate returns, and unpopular from the necessity it involved of prying into the business and private concerns of the people. Great use has however been made of it in England, where one has been imposed ever since 1842, undergoing in the mean time 18 alterations, the rate ranging from 16*d.* in the pound to 2*d.* In some tax laws incomes are graded, and those are taxed least which are derived from property otherwise taxed, or which for any reason it is thought should not be taxed as high as others. In America an income tax has always been exceptional. Excise taxes are laid in great variety, and in some countries produce the larger portion of the revenue. The heaviest are usually those on the manufacture of liquors; these have sometimes been made so heavy as to furnish strong inducements to evasion, and by various ingenious contrivances, combined usually with corruption of the revenue officers, the heavy tax is made less productive than a light one. Excise taxes are also laid on employments in various forms, on the profits of business and of corporations, &c. A succession tax, or a tax on the privilege of succeeding to an inheritance or to a testamentary gift, has been customary. When the succession is collateral, or out of the immediate family of the deceased, it comes in diminution of a new capital and will not be burdensome; but when paid by the immediate family of the deceased, the burden is more felt, because that from which the tax is taken was, for all purposes of comfort and enjoyment, the property of the family before. Customs taxes are in some countries next in productiveness to excise taxes, while in others they are much more productive. They are favorite taxes with governments because they are easy of collection, and because the people submit to them more willingly than to either the direct or the indirect internal taxes. They are objectionable because of the strong invitation they hold out to smuggling, which is greater in proportion as the tax is heavy, and also because of the temptation they offer for discriminating legislation for the benefit of particular occupations or to build up monopolies. Protective taxation is usually laid in this form. Either an excise or a customs tax will be productive in proportion as the article taxed is one in general use, and as the government succeeds in collecting the tax and preventing evasions. An export tax is not often laid, it being thought impolitic as tending to diminish exportation and production, and also because, to the extent that it seems to transfer to purchasers in other countries the burdens of the government imposing it, the tendency is to invite retaliatory legislation. A property tax by value has very generally been regarded in America as the most equal and just of all taxes. Practically it falls mainly on real property, from the difficulty of discovering and listing personalty except in its most tangible forms. Stamp taxes are laid in various forms: on manufactured articles, bills of exchange, checks, deeds, contracts, and other instruments of business or traffic, on the process of courts, letters of administration, &c., and sometimes on newspapers. No taxes are so easily, cheaply, or conveniently collected as these, and when levied on articles selected with a view to a fair distribution of the burden, none could be more just. In the United States they are generally abandoned except for the purposes of the excise on manufactures. The enjoyments and amusements of the wealthier classes are sometimes taxed specially, the taxes being imposed in respect to their servants, horses, carriages, dogs, plate, &c. The interest of money is sometimes taxed specially; so are dividends of corporations and joint stock companies; so sometimes are indentures of apprenticeship, and even marriages. Many light taxes are laid for regulation merely, usually in the form of license fees. A principle generally accepted is, that articles of luxury should be selected for taxation to the relief of articles of prime necessity. This tends to cast the burden upon those best able to bear it, and at the same time leaves every man to tax himself, since his purchases are made of choice and not from necessity. But this by no means has the effect at all times to make the weight of taxes fall upon the wealthier classes. Mr. R. D. Baxter estimates the taxes paid by the manual labor classes of Great Britain on alcoholic drinks and tobacco at $6\frac{1}{10}$ per cent. of their income, and those paid by the upper and middle classes on the same articles at $2\frac{3}{10}$ per cent.—The official figures of European budgets convey no adequate idea of the relative taxation in the respective countries, because in one country they may embrace the taxes levied for many purposes which in another will be provided for by taxes not brought into the corresponding budget. Furthermore, no adequate returns are anywhere made of the items of local taxation, which constitute a large proportion of the aggregate taxes. These local taxes in Great Britain are estimated to exceed £30,000,000. Any comparison between the taxation of the United States and that of the European countries would also be likely to mislead, unless it brought into view the taxation of the several states as well as that of the nation. Taxation in the United States ranges itself under the three heads of federal, state, and municipal. The first is laid almost wholly in the form of customs and excise duties. The figures for the fiscal year 1875 were:

| | | |
|---|---|---|
| Customs duties | | $157,167,722 00 |
| Taxes on distilled liquors | $52,081,991 12 | |
| " on fermented liquors | 9,144,391 66 | |
| " on tobacco | 37,303,670 06 | |
| Stamp taxes | 6,088,590 42 | |
| Taxes on banks | 4,096,860 87 | |
| Penalties and other items | 1,138,700 98 | |
| Total internal taxes | | 109,849,205 11 |
| Total of taxes | | $267,016,927 11 |

State taxation is usually laid for general state purposes only. The bulk of all state taxation is laid upon property by a periodical valuation. In some states these are supplemented by taxes on occupations or "privileges," on the franchises of corporations, &c. Taxes on those occupations which are transient and those which are thought to require peculiar supervision and regulation are usual in all the states. Municipal or local taxation is commonly very much heavier than state taxation. It embraces: 1, all taxes laid for the general purposes of counties, cities, boroughs, towns, and villages; and 2, those local taxes which are usually called assessments, and which are laid in special districts supposed to be peculiarly benefited by the construction of some public work, and by some rule of apportionment which proposes to charge each item of property within the district in proportion to the benefit it will receive. Taxes on this principle are often, though not always, laid for the opening and improvement of streets, for sewerage and lighting in cities, for country drains, for levees and embankments, &c. The legislature directs these to be provided for by general taxation of the municipality, or by local assessments, as it deems most just, or it confers upon the municipality within which the work is to be done a discretion in the premises.—The methods of collecting taxes are various. Formerly in some countries the collection of the revenue was farmed out to contractors, but this led to enormous abuses and oppressions, and is no longer thought of. Customs duties are usually collected by requiring everything imported to pass through the hands of government officers, and the tax to be paid before the goods pass beyond their control. Excise taxes may be imposed in the form of stamps, and collected in a sale of the stamps, to be affixed either by the person taxed or by some official. Assessed taxes are mainly collected by a collector to whom a tax list and warrant is issued, and who is authorized to distrain goods, and perhaps to take the body of the person taxed. In the United States taxes on lands are generally permitted to be enforced by a sale of the lands after other means of collection are exhausted. Much use is made of penalties under revenue laws, not only for the punishment of frauds and evasions, but also to compel the furnishing of lists, returns, &c.—Many things are usually exempt from taxation. Indeed, any taxation is only a selection of subjects to be taxed, leaving everything else exempt; but where special classes of persons, occupations, property, &c., are taxed, many exemptions are made. Public property is usually exempt, and this includes court houses, public school buildings, asylums, &c. Houses of worship are also generally exempted, and sometimes the property of clergymen; the idea being that this indirect encouragement to religious worship is for the good of the state, and also, perhaps, that as the community in general contribute in some form to the maintenance of churches, this exemption produces no considerable inequality. Special exemptions of individuals in any class taxed are usually unjust, and in the United States, except when made for a consideration, must be regarded as forbidden by constitutional principles.—Taxation and protection are regarded as reciprocal rights and duties. But protection is the consideration rather for the liability to taxation than for actual taxation; as, if the government should see fit to collect all its taxes from lands, persons owning no lands and therefore not taxed, but liable to be taxed, would be equally entitled to protection with the land owner himself. In Great Britain and the United States it is a constitutional maxim that taxation and representation go together, and the people's representatives vote the taxes which the people are to pay. A violation of this maxim led to the American revolution. The exact force of the maxim is not well determined. It is not usually in doubt so far as the general taxes for the use of the state are concerned: these must be granted by the legislature; but in the case of local taxes some questions remain to be determined. There can be no doubt that local powers to tax are not inherent in the municipalities, but must be conferred by the state. Usually they are conferred with proper restrictions, and the municipalities are then left to exercise them at discretion. And it must be conceded that when the powers are to be employed for purely local purposes in which the commonwealth at large has no concern, this maxim would be disregarded if liberty in the premises were not left to the people directly interested; and this in the United States is customary.—See Leone Levi, "On Taxation, how it is Raised and how Expended" (London, 1860); Parieu, *Traité des impôts considérés sous le rapport historique, économique et politique en France et à l'étranger* (5 vols., Paris, 1862-'4); Sir Morton Peto, "Taxation, its Levy and Expenditure, past and future" (New York, 1866); R. Dudley Baxter, "The Taxation of the United Kingdom" (London, 1869), and "Taxation and Local Government" (1874); George J. Goschen, M. P., "Local Taxation" (London, 1872); Sargeant, "Taxation, Past, Present, and Future" (London, 1874); R. S. Blackwell, "Tax Titles" (3d ed., Boston, 1874); "Local Government and Taxation," edited by J. W. Probyn ("Cobden Club Essays," 1875); Francis Hilliard, "The Law of Taxation" (Boston, 1875); and Thomas M. Cooley, "The Law of Taxation" (Chicago, 1876).

**TAXIDERMY** (Gr. τάξις, arrangement, and δέρμα, a skin), the art of preparing the skins of animals so that they retain their natural appearances, and also of arranging them in the forms and natural positions of the animals from which they are taken. This often includes the preservation of the skeleton or parts of the skeleton, which is replaced as being the

most convenient model or frame on which the skin can be placed. The art also includes the preservation of the whole of the bodies of small animals, which in such cases is synonymous with embalming. The principal operations in taxidermy are the removal of the skin, which requires much care and dexterity, and its treatment with some preserving preparation, as arsenical soap, composed of arsenic 1 oz., white soap 1 oz., carbonate of potash 1 dr., distilled water 6 drs., camphor 2 drs. This soap prevents the attacks of insects and keeps the skin soft. The larger skins are often treated with the following preparation, called "preservation powder:" arsenic and burnt alum each 1 lb., ground oak bark 2 lbs., camphor ½ lb. Gloves should be used in applying the preparation. Corrosive sublimate, carbolic acid, and more recently salicylic acid, have been used in different ways with success. There are so many details that directions cannot be given in this place.—See directions by Prof. S. F. Baird in the "Report of the Smithsonian Institution" for 1856; Swainson's "Taxidermy," forming a volume of Lardner's "Cabinet Cyclopædia;" and the "Taxidermist's Manual," by Capt. Thomas Brown, F. Z. S. (New York, 1875).

**TAY,** a river and loch of Perthshire, Scotland. The river rises in a small loch on the border of Argyleshire, and is called the Fillan until it passes through Loch Dochart, 8 or 9 m., and thence to Loch Tay, 10 m. further, it is generally known as the Dochart. Near Loch Tay it receives the Lochie, and below that loch the river Lyon and numerous other tributaries. It is nearly 120 m. long, and describes almost a semicircle, flowing mainly N. E. and S. E., until it reaches Perth, whence it flows nearly E. through the frith of Tay into the North sea. It has tide water and is navigable for vessels of 9 ft. draught to Perth. Above this point it flows through the finest valley of Scotland, and it discharges a larger volume of water than any other river of the British islands. Its salmon fisheries are celebrated. Loch Tay is about 16 m. long and 1 m. wide, with steep, precipitous banks, and is said to have been sounded to a depth of 600 ft. Ben Lawers, on its N. W. shore, rises to a height of 3,984 ft.

**TAYGETUS.** See LACONIA.

**TAYLOR,** the name of six counties in the United States. **I.** A N. county of West Virginia, intersected by the Tygart's Valley river; area, 130 sq. m.; pop. in 1870, 9,367, of whom 343 were colored. The surface is very hilly, and the soil in some parts fertile. Iron ore and bituminous coal are abundant. The chief productions in 1870 were 28,684 bushels of wheat, 95,439 of Indian corn, 45,166 of oats, 10,305 of potatoes, 97,233 lbs. of butter, 17,233 of wool, and 6,710 tons of hay. There were 1,685 horses, 1,791 milch cows, 4,638 other cattle, 6,000 sheep, and 2,651 swine; 4 tanneries, 2 iron founderies, 5 flour mills, 7 saw mills, and 2 machine shops. Capital, Pruntytown. **II.** A W. county of Georgia, bounded N. and E. by Flint river and drained by Whitewater and other creeks; area, about 400 sq. m.; pop. in 1870, 7,143, of whom 2,962 were colored. The surface is undulating and the soil generally fertile. It is intersected by the Southwestern railroad. The chief productions in 1870 were 5,962 bushels of wheat, 119,269 of Indian corn, 6,491 of oats, 16,344 of sweet potatoes, and 3,559 bales of cotton. There were 348 horses, 654 mules and asses, 1,320 milch cows, 3,463 other cattle, 1,159 sheep, and 6,339 swine; 1 cotton factory, 2 flour mills, and 9 saw mills. Capital, Butler. **III.** A N. county of Florida, bounded S. W. by the gulf of Mexico and W. by the Ocilla river, and drained by several streams; area, 1,100 sq. m.; pop. in 1870, 1,453, of whom 79 were colored. The surface is level and the soil sandy. The chief productions in 1870 were 20,625 bushels of wheat, 9,535 of sweet potatoes, 244 bales of cotton, 6 hogsheads of sugar, and 4,369 gallons of molasses. There were 117 horses, 1,040 milch cows, 4,340 other cattle, and 4,650 swine. Capital, Perry. **IV.** A N. W. county of Texas, drained by Clear fork of Brazos river; area, 900 sq. m.; returned in 1870 as having no population. The surface is mostly table land, with little timber or water. **V.** A central county of Kentucky, drained by affluents of Green river; area, about 275 sq. m.; pop. in 1870, 8,226, of whom 1,850 were colored. The surface is hilly and the soil fertile. The chief productions in 1870 were 27,744 bushels of wheat, 239,581 of Indian corn, 55,867 of oats, 11,959 of potatoes, 1,209,830 lbs. of tobacco, 17,040 of wool, 95,869 of butter, and 1,219 tons of hay. There were 2,414 horses, 1,689 milch cows, 2,306 other cattle, 8,046 sheep, and 13,508 swine. Capital, Campbellsville. **VI.** A S. W. county of Iowa, bordering on Missouri and drained by East Nodaway, One Hundred and Two, and Platte rivers; area, 560 sq. m.; pop. in 1870, 6,989. The surface is generally level and the soil fertile. The chief productions in 1870 were 56,852 bushels of wheat, 438,089 of Indian corn, 85,886 of oats, 38,507 of potatoes, 33,868 lbs. of wool, 120,167 of butter, and 14,174 tons of hay. There were 2,744 horses, 2,559 milch cows, 6,898 cattle, 9,953 sheep, and 10,568 swine; 2 flour mills, 3 saw mills, and 1 woollen factory. Capital, Bedford.

**TAYLOR, Bayard,** an American author, born in Kennett Square, Chester co., Pa., Jan. 11, 1825, died in Berlin, Prussia, Dec. 19, 1878. In 1842 he became an apprentice in a printing office. In 1844–'5 he made a pedestrian tour in Europe, and in 1846 published "Views Afoot, or Europe seen with Knapsack and Staff." For a year he edited a newspaper in Phœnixville, Pa., then went to New York, wrote for the "Literary World," and soon after joined the editorial staff of the "Tribune," in which journal many of his subsequent works of travel first appeared. In 1849 he visited

California, and returned home by the way of Mexico. In 1851 he set out on a protracted tour in the East, in the course of which he ascended the Nile to lat. 12° 30′ N., and afterward traversed large portions of Asia Minor, Syria, and Europe; and in the latter part of 1852 he made a new departure from England, crossing Asia to Calcutta, and thence proceeding to China, where he joined the expedition of Commodore Perry to Japan; and he afterward made several other journeys. In 1862–'3 he was secretary of legation at St. Petersburg, and part of the time chargé d'affaires. In 1874 he revisited Egypt, and attended the millennial celebration in Iceland; and in Feb., 1878, he was appointed minister to Germany, where he had previously resided several years at intervals. He was also well known as a lecturer. Besides his "Views Afoot," he published "El Dorado, or Adventures in the Path of Empire" (2 vols. 12mo, 1850); "A Journey to Central Africa" (1854); "The Lands of the Saracen" (1854); "A Visit to India, China, and Japan" (1855); "Northern Travel: Summer and Winter Pictures of Sweden, Denmark, and Lapland" (London, 1857; New York, 1858); "Travels in Greece and Russia" (1859); "At Home and Abroad, a Sketch Book of Life, Scenery, and Men" (1859; 2d series, 1862); "Colorado, a Summer Trip" (1867); "By-Ways of Europe" (1869); and "Egypt and Iceland" (1874). His volumes of poems are: "Ximena, or the Battle of the Sierra Morena, and other Poems" (Philadelphia, 1844); "Rhymes of Travel, Ballads, and other Poems" (1848); "The American Legend," a poem delivered before the Phi Beta Kappa society of Harvard university (1850); "Book of Romances, Lyrics, and Songs" (1851); "Poems and Ballads" (1854); "Poems of the Orient" (1855); "Poems of Home and Travel," a selection from his early lyrics (Boston, 1855); "The Poet's Journal" (1862); "The Picture of St. John" (1866); "The Ballad of Abraham Lincoln" (1869); "The Masque of the Gods" (1872); "Lars, a Pastoral of Norway" (1873); "The Prophet, a Tragedy" (1874); and "Home Pastorals, Ballads, and Lyrics" (1875). He also published the novels "Hannah Thurston, a Story of American Life" (1863), "John Godfrey's Fortunes" (1864), "The Story of Kennett" (1866), and "Joseph and his Friend" (1870). He translated in the original metres both parts of Goethe's "Faust" (1870–'71), and edited a "Cyclopædia of Modern Travel" (Cincinnati, 1856), "Frithiof's Saga," translated by W. L. Blackley from the Swedish of Tegnér (1867), Auerbach's "Villa on the Rhine" (2 vols., 1869), and "Illustrated Library of Travel, Exploration, and Adventure" (vols. i.–iv., 1872–'4). Several of his works have been translated into German, French, and Russian. He had been long engaged upon a biography of Goethe, which he left unfinished.

**TAYLOR, Brook,** an English mathematician, born at Edmonton, Aug. 18, 1685, died in or near London, Dec. 29, 1731. In 1701 he entered St. John's college, Cambridge, and in 1708 wrote his treatise on the "Centre of Oscillation," which was published in 1713 in the "Philosophical Transactions." In 1712 he was chosen a fellow of the royal society, and from 1714 to 1718 was its secretary; and he contributed papers on magnetism and mathematical subjects. His *Methodus Incrementorum* (1715) is the first treatise in which the calculus of finite differences is proposed for consideration, and contains the first enunciation of the celebrated theorem which bears his name. In 1715 he conducted a controversial correspondence with Count Raymond de Montmort on the tenets of Malebranche, and in 1719 he published his "New Principles of Linear Perspective." His *Contemplatio Philosophica* was published posthumously, with a memoir by his grandson, Sir William Young (1793). He left a number of works which are still unpublished.

**TAYLOR, Edward T.,** an American clergyman, born in Richmond, Va., Dec. 25, 1793, died in Boston, April 6, 1871. From 7 to 17 years of age he was a sailor boy. Captured on a privateer in the war of 1812, he was imprisoned at Dartmoor, England, and acted as chaplain to the prisoners. In connection with the New England Methodist conference he began stated labors and continued nine years, till about 1828, when he became chaplain of the Boston seamen's bethel, which post he retained till his death, acquiring a world-wide fame as the eloquent sailors' preacher. For many years he was known as Father Taylor. He visited Europe in 1832, and Palestine in 1842; and he was chaplain of the Macedonian, sent in 1846 to the relief of the starving poor of Ireland.

**TAYLOR, George,** a signer of the Declaration of Independence, born in Ireland in 1716, died in Easton, Pa., Feb. 23, 1781. After receiving a good education, he came to America as a "redemptioner," and bound himself for a term of years to an iron manufacturer at Durham, Pa. His employer subsequently made him his clerk, and after his death Taylor married his widow and became master of the establishment. He was a member of the provincial assembly from 1764 till 1770, when he was made a judge of the county court and colonel of militia. In October, 1775, he was again elected to the provincial assembly. He was elected to the continental congress on July 20, 1776, signed the Declaration on Aug. 2, and in March, 1777, retired from congress.

**TAYLOR, Sir Henry,** an English poet, born in 1800. In 1824 he entered the colonial office, where he has long been one of the five senior clerks. His earliest publication was "Isaac Comnenus, a Play" (1827), and he is best known by two dramas in blank verse, "Philip van Artevelde" (1834) and "Edwin the Fair" (1842). His other works include "The Eve of the Conquest, and other Poems" (1847); "Notes from Life, in Six Essays" (1847); "Notes from Books, in Four Essays" (1849);

"The Virgin Widow, a Play" (1850); and "St. Clement's Eve, a Play" (1862). A collective edition of his plays and poems was published in 1863 (3 vols. 8vo).

**TAYLOR, Isaac,** an English author, born at Lavenham, Suffolk, Aug. 17, 1787, died at Stanford Rivers, Essex, June 28, 1865. His father, Isaac Taylor, originally a line engraver, became a dissenting minister, and wrote several popular books for children. His mother, Ann Taylor, wrote "Maternal Solicitude" and other educational works. The son was trained as an artist, but devoted himself to literature, and also displayed much mechanical ingenuity in his invention of an engraving machine which was employed in producing the plates for Traill's Josephus, and a machine for engraving patterns on rollers for calico printing, now in use in Manchester. Some of the designs from his pencil were engraved for Boydell's Bible. Though brought up as a dissenter, he became a member of the established church. In 1862 he received a civil service pension of £100 for his services to literature in the departments of history and philosophy. He published "Elements of Thought" (1822); "History of the Transmission of Ancient Books to Modern Times" (1827); "The Process of Historical Proof Exemplified and Explained" (1828); "Balance of Criminality, or Mental Error compared with Immoral Conduct" (1828); and a translation of Herodotus with notes (1829). In 1829 appeared anonymously his "Natural History of Enthusiasm," which was received with extraordinary favor, and was followed by "A New Model of Christian Missions" (1829); "Saturday Evening" (1832); "Fanaticism" (1833); "Spiritual Despotism" (1835); and "Physical Theory of Another Life" (1836), the last leading to the surrender of the author's *incognito.* His other works are: "Home Education" (1838); "Ancient Christianity, and the Doctrines of the Oxford Tracts for the Times" (8 parts, 1839–'40; 4th ed., with supplement and indexes, 2 vols. 8vo, 1844); "Man Responsible for his Dispositions, Opinions, and Conduct" (1840); "Lectures on Spiritual Christianity" (1841); "Loyola, and Jesuitism in its Rudiments" (1849); "Wesley and Methodism" (1851); "The Restorations of Belief" (1855); "The World of Mind" (1857); "Logic in Theology, and other Essays" (1859); "The Liturgy and the Dissenters," and "Ultimate Civilization, and other Essays" (1860); "The Spirit of Hebrew Poetry" (1861); and "Considerations on the Pentateuch" (1863).—His brother JEFFREYS published a number of popular books for young people. His sisters ANN (died 1866) and JANE (1783–1824) published "Original Poems" and "Hymns" for children, and "Hymns" for Sunday schools. (See "Autobiography and other Memorials of Mrs. Gilbert, formerly Ann Taylor," edited by Josiah Gilbert, 2 vols., London, 1874.) Jane also published "Display," a tale (1815), and "Contributions of Q. Q." (1824); and her "Memoirs, Correspondence, and Poetical Remains" appeared in 1825 (2 vols.).—His son ISAAC, a clergyman of the established church, has published "Words and Places" (1864; enlarged ed., 1865), which attempts to give a complete explanation of the local names of Great Britain; "The Family Pen: Memorials Biographical and Literary of the Taylor Family of Ongar" (2 vols., 1867); and "Etruscan Researches" (1874).

**TAYLOR, Isidore Séverin Justin,** baron, a French author of English origin, born in Brussels, Aug. 15, 1789. After studying art he served several years in the French army, reaching the rank of major, and afterward travelled in Italy, Greece, and the East, bringing back rich collections, which he placed in the galleries and museums of Versailles and Paris. He exerted himself to procure from the French chambers the restoration of the principal monuments of the middle ages in France; in 1824 was made royal commissary of the Comédie Française; and at the direction of the government twice visited Egypt, and negotiated the transfer to France of the obelisks of Luxor and other Egyptian antiquities. He was made a senator in 1869. In connection with C. Nodier and De Caillieu, he edited the illustrated *Voyages pittoresques et romantiques dans l'ancienne France* (fol., 1820–'54); *Voyage pittoresque en Espagne, en Portugal et sur la côte d'Afrique de Tanger à Tétouan* (4to, 1826 *et seq.*); *La Syrie, l'Égypte, la Palestine et la Judée* (4to, 1837 *et seq.*); *Pèlerinage à Jérusalem* (1841); and *Voyage en Suisse, en Italie, en Sicile, en Angleterre, en Écosse, en Allemagne, en Grèce,* &c. (1843).

**TAYLOR, Jeremy,** an English theologian, born in Cambridge in 1613, died at Lisburn, Ireland, Aug. 13, 1667. His father was a barber and surgeon, and he was educated as a sizar at Cambridge, but obtained a fellowship at Oxford in 1636, and in 1638 the rectory of Uppingham in Rutland. In the civil wars he adhered to Charles I., who made him his chaplain, and for a defence of episcopacy written at the king's request commanded his admission to the degree of D. D. in 1642. The same year his rectory was sequestered by the parliament, but he continued to write for the royal cause till 1645, when he was obliged to retire into Wales, where he maintained himself by teaching school, and wrote some of his most important works. His "Liberty of Prophesying" (1647), in behalf of toleration, was published at the very crisis of the civil struggle. This was followed by his "Holy Living and Dying" (1650–'51), now perhaps the best known of his works, and "The Great Exemplar, or the Life and Death of the Holy Jesus" (1653). He subsequently preached occasionally in London, and suffered several short imprisonments on account of his royalist sympathies. He was also censured by his own party for some expressions thought to indicate Romanist views,

and in 1658 was imprisoned in the tower in consequence of his publisher having prefixed to his collection of offices a print of Christ in the attitude of prayer. He was released through the efforts of Evelyn, and on the invitation of the earl of Conway removed to the north of Ireland. In 1660 he went to London to publish his "Ductor Dubitantium," the most extensive work on casuistry in the English language. While there he signed the royalist declaration of April 24, and Charles II. on his restoration nominated him bishop of Down and Connor, to which the bishopric of Dromore was soon added. He was shortly afterward made a member of the Irish privy council, and elected vice chancellor of the university of Dublin. His second wife was a natural daughter of Charles I. As a writer of sermons Bishop Taylor stands preëminent. His complete works were published by Bishop Heber with a memoir (15 vols., London, 1820–'22), and his life by R. A. Willmott (London, 1847).

**TAYLOR, John**, an English author, called "the water poet," born in Gloucester in 1580, died in London in 1654. He was educated at the free school of Gloucester, and was apprenticed to a London waterman, an occupation which he followed during the greater part of his life. In 1596 he served in the fleet under the earl of Essex, and was present at the attack upon Cadiz. After his return he plied on the Thames, and collected the lieutenant of the tower's demand on imported wines. Subsequently he kept a public house in Phœnix lane, Long Acre. His publications, in prose and in verse, amounting to upward of 80, are of value as illustrations of opinions and manners during the first half of the 17th century. They were published in folio in 1630. Two of the most curious of his prose works are devoted to descriptions of a journey on foot to Scotland in 1618, and of another, made principally in a boat, from London to Hereford in 1641.

**TAYLOR, John**, an English minister, born near Lancaster in 1694, died at Warrington, March 5, 1761. He was educated at Whitehaven, and settled for 18 years as teacher and minister at Kirkstead in Lincolnshire. In 1733 he was chosen pastor of a Presbyterian congregation at Norwich, where he preached for 24 years, and avowed anti-Trinitarian sentiments. In 1757 he became principal of the dissenting academy at Warrington. His principal published works are: "The Scripture Doctrine of Original Sin" (1738); "A Paraphrase on the Epistle to the Romans" (1745); "The Scripture Doctrine of the Atonement" (1750); "An Hebrew English Concordance" (2 vols. fol., 1754–'7); and "A Scheme of Scripture Divinity" (1762), edited by his son.

**TAYLOR, Nathaniel William**, an American clergyman, born in New Milford, Conn., June 23, 1786, died in New Haven, March 10, 1858. He graduated at Yale college in 1807, studied theology, and in 1812 was ordained pastor of the first church (Congregational) in New Haven, and became eminent as a preacher. In 1822 he was called to the Dwight professorship of didactic theology in Yale college, in which office he continued till his death. In 1828 he preached at New Haven the *concio ad clerum*, in which he set forth views upon human depravity and other related doctrines which caused him to be widely denounced for heresy; and for several years he maintained a vigorous discussion of these and similar topics, through the quarterly "Christian Spectator." Since his death four volumes of his works have been published, viz.: "Practical Sermons" (8vo, New York, 1858); "Lectures on the Moral Government of God" (2 vols., 1859); and "Essays, Lectures, &c., upon Select Topics in Revealed Theology" (1859).

**TAYLOR, Richard**, an English printer, born in Norwich, May 18, 1781, died in Richmond, Dec. 1, 1858. He studied the classical and other languages and literature while learning the printer's trade in London, and in 1803 established himself in business with his father; and his press soon became the medium through which nearly all the more important works in scientific natural history were published. In 1807 he became a fellow of the Linnæan society, and in 1810 was elected its under-secretary, an office which he held nearly half a century. He also attached himself from the commencement to the "British Association for the Advancement of Science." In 1822 he became a joint editor of the "Philosophical Magazine," and in 1838 he established the "Annals of Natural History." His own literary labors, which were principally in the field of Biblical and philological research, comprise an edition of Tooke's "Diversions of Purley" (1829 and 1840), enriched with notes; Warton's "History of English Poetry" (1840), in the reëditing of which he took the chief part; "Taylor's Scientific Memoirs," &c.

**TAYLOR. I. Stephen William**, an American educator, born in Adams, Mass., Oct. 23, 1791, died at Hamilton, N. Y., Jan. 7, 1856. He graduated at Hamilton college, N. Y., in 1817, and became a teacher. From 1838 to 1845 he was professor of mathematics and natural philosophy in Hamilton college (now Madison university), from 1846 to 1851 president of the university of Lewisburg, Pa., and from 1851 till his death president of Madison university, of which he published a historical sketch. **II. Benjamin Franklin**, an American author, son of the preceding, born in Lowville, N. Y., in 1822. He was educated at Madison university. For many years he was literary editor of the Chicago "Evening Journal," and during the civil war he was its principal correspondent with the armies of the west. After the war he settled at La Porte, Ind. He has published "The Attractions of Language" (1845); "January and June," essays and poems (1853); "Pictures in Camp and Field" (1867); "The World on Wheels," railroad sketches (1873); "Old Time Pictures and

Sheaves of Rhyme" (1874); and "Songs of Yesterday" (1875).

**TAYLOR, Thomas**, an English scholar, surnamed the "Platonist," born in London, May 15, 1758, died at Walworth, Nov. 1, 1835. He studied the classics, mathematics, and chemistry, and became clerk in a banking house. He issued, in the course of 40 years, translations of part or the whole of the hymns of Orpheus, the works of Plato (5 vols. 4to), Proclus, Julian, Pausanias, Plotinus, Apuleius, Aristotle, Maximus Tyrius, Demophilus, Iamblichus, Hierocles, Porphyry, Celsus, Ocellus Lucanus, and Olympiodorus, and the "Chaldean Oracles." He also published works on geometry and arithmetic, on the Eleusinian and Bacchic mysteries (new ed., with introduction and notes by Alexander Wilder, M. D., 1875), on "The Rights of Brutes" (in ridicule of Paine's "Rights of Man"), a new edition of Hedericus's "Greek Lexicon" with additions, "History of the Restoration of the Platonic Theology," "Miscellanies in Prose and Verse," &c. His works amounted to 55 vols.

**TAYLOR, Tom**, an English author, born in Sunderland in 1817. He graduated at Trinity college, Cambridge, and became a fellow. He was for two years professor of English literature in University college, London, was called to the bar in 1845, and in 1850 became assistant secretary to the board of health, and in 1854 secretary. Since 1858 he has been secretary to the local government act office. He is the author of more than 100 dramatic pieces, among the most successful of which are "Still Waters Run Deep," "The Unequal Match," "The Overland Route," "The Contested Election," "Our American Cousin," "The Ticket-of-Leave Man," and "'Twixt Axe and Crown." In conjunction with Charles Reade he has written "Masks and Faces" and other plays. He has also published a "Life of Benjamin Robert Haydon" (3 vols. 8vo, 1853); an editorial preface and continuation of the "Autobiographical Recollections of C. R. Leslie" (2 vols. 8vo, 1860); a "Handbook to the Pictures of the International Exhibition of 1862" (8vo, 1862); "Birket Foster's Pictures of English Landscape, engraved by the Brothers Dalziel, with Pictures in Words by Mr. Tom Taylor" (4to, 1862); "Ballads and Songs of Brittany," translated from the French of Villemarque (4to, 1865); and, in conjunction with C. W. Franks, a "Catalogue of the Works of Sir Joshua Reynolds" (8vo, 1869).

**TAYLOR, William Cooke**, an Irish author, born in Youghal, April 16, 1800, died in Dublin, Sept. 12, 1849. He was educated at the university of Dublin, and went to London, where he resided till two years before his death. His chief works are: "Historical Miscellany" (12mo, 1829); "History of France and Normandy" (1830); "History of the Civil Wars in Ireland" (2 vols., 1831); "History of Mohammedanism and its Sects" (1834); "History of Popery" (1837); "The Bible Illustrated from Egyptian Monuments" (1838); "Manual of Modern History" (8vo, 1838); "Manual of Ancient History" (1839); "Natural History of Society" (2 vols., 1840); Romantic Biography of the Age of Elizabeth" (2 vols., 1842); "History of British India" (1842); "Revolutions, Insurrections, and Conspiracies of Europe" (2 vols., 1843); and "Memoirs of the House of Orleans" (3 vols., 1849). He also edited Bacon's essays and Chapman's translation of Homer. In 1846 he was employed by the British government to inquire into the system of education on the continent.

**TAYLOR, William Mackergo**, an American clergyman, born at Kilmarnock, Ayrshire, Scotland, Oct. 23, 1829. He graduated at the university of Glasgow in 1849, studied theology in Edinburgh, was licensed to preach in 1852, and in 1853 was ordained pastor of the United Presbyterian church at Kilmaurs. In 1855 he accepted a call to the United Presbyterian church at Derby road (Bootle), near Liverpool, and remained there for 16 years. In 1871 he visited the United States as a delegate of the United Presbyterian church to the general assembly of the Presbyterian church in the United States at Chicago. In 1872 he became pastor of the Broadway Tabernacle church in New York. He has published "Life Truths" (London, 1862); "The Miracles: Helps to Faith, not Hindrances" (Edinburgh, 1865), written as a reply to Renan's "Life of Jesus;" "The Lost Found and Wanderer Welcomed" (1870); "David, King of Israel" (New York, 1874); and "Elijah the Prophet" (1876).

**TAYLOR, Zachary**, twelfth president of the United States, born in Orange co., Va., Sept. 24, 1784, died in Washington, D. C., July 9, 1850. His father, Col. Richard Taylor, served throughout the revolutionary war, and removed in 1785 from Virginia to Kentucky, where he had an extensive plantation in the neighborhood of Louisville. Zachary was engaged till his 24th year on the plantation. His brother Hancock, a lieutenant in the United States army, died in 1808, and the vacant commission was assigned to Zachary. He was made a captain in November, 1810, and after the declaration of war against Great Britain was placed in command of Fort Harrison, a blockhouse and stockade on the Wabash river, about 50 m. above Vincennes. This was the first object of attack by the Indians, a large force of whom invested it in September, 1812, and after professions of peace made a furious night assault and set fire to the lower buildings of the fort. Taylor had but 50 men, of whom two thirds were ill; but after a sharp conflict of several hours he extinguished the flames and repulsed the assailants with severe loss. For his conduct on this occasion he received from President Madison the rank of major by brevet, the first instance in the service of this species of promotion. A few months later he took part in a successful expedition led by Gen. Hopkins

against the Indian villages, and in 1814, with the full rank of major, commanded an expedition against the British and Indians on Rock river. On the restoration of peace in 1815, congress reduced the army and annulled many of the promotions made during the war. Taylor was reduced to the rank of captain, and in consequence resigned his commission and retired to his plantation near Louisville. Being soon reinstated as major, he was employed for several years alternately on the N. W. frontier and in the south, where in 1822 he built Fort Jesup. In 1819 he became lieutenant colonel, and in 1832 colonel. In the latter year he was engaged in the Black Hawk war, and was then ordered to Prairie du Chien, where he took command of Fort Crawford, which had been erected under his superintendence. In 1836–'40 he served in Florida. On Dec. 25, 1837, he defeated the Indians in the desperate and decisive battle of Okeechobee, and was promoted to the rank of brigadier general by brevet; and in April, 1838, he was made commander-in-chief in Florida. In 1840 he was appointed to the command of the first department of the army in the southwest. He purchased at this time an estate at Baton Rouge, to which he removed his family. Congress having in March, 1845, passed the joint resolution annexing Texas, Gen. Taylor was directed to defend it against invasion from Mexico. In July he embarked at New Orleans with 1,500 troops, and in the beginning of August encamped with them at Corpus Christi, Texas, where he was reënforced, so that in November his forces amounted to about 4,000 men. The administration desired to bring the Mexican question to a crisis, without, if possible, incurring the responsibility of beginning a war. Indirectly, therefore, it endeavored to induce Gen. Taylor to advance his forces into the disputed territory; but he disregarded all hints to that effect, and would not move till explicitly ordered by the president. Positive instructions were at length sent, and on March 8, 1846, the army began its advance toward the Rio Grande, and on the 28th reached the banks of that river opposite Matamoros. Here it encamped and erected Fort Brown, which commanded Matamoros, where the Mexicans were also throwing up batteries and redoubts. On April 12 Gen. Ampudia, the Mexican commander, addressed a note to Gen. Taylor requiring him within 24 hours to break up his camp and retire beyond the Nueces, "while our governments are regulating the pending question in relation to Texas," and informing him that his non-compliance would be regarded by the Mexicans as equivalent to a declaration of war. Gen. Taylor replied that he was acting under instructions which did not permit him to return to the Nueces, and that if the Mexicans saw fit to begin hostilities he should not avoid the conflict. Ampudia was soon after superseded by Arista, who early in May crossed the Rio Grande with 6,000 men, and on the 8th of that month attacked and was defeated by Gen. Taylor with 2,300 men at Palo Alto, a few miles from Matamoros. (See PALO ALTO.) The Mexicans retreated to Resaca de la Palma, and on the following day again gave battle to the Americans, who after a severe contest routed them and drove them across the Rio Grande. The total loss of the Mexicans in these battles amounted to about 1,000 men. Taylor was promoted to the rank of major general, took possession of Matamoros on May 18 without opposition, and remained there till September, when he marched against Monterey, which he reached on Sept. 9 with a force of 6,625 men, mostly volunteers. The place was defended by Ampudia with about 10,000 regular troops. On the 19th Taylor ordered an assault, and after several days' desperate fighting Ampudia capitulated on the 24th. (See MONTEREY.) Taylor made Monterey his headquarters, but occupied with a strong detachment the city of Saltillo, the capital of the state of Coahuila. He was making preparations for an advance upon San Luis Potosí, when the best part of his force was transferred to the expedition against Vera Cruz, under Gen. Scott. He was left with only 5,000 men, of whom but 500 were regulars, the rest being volunteers who had never seen a battle. He received intelligence that Santa Anna had concentrated at San Luis Potosí the flower of the Mexican army to the number of 21,000 veteran troops, and was moving rapidly to attack him in the valley of the Rio Grande. Gen. Taylor on Feb. 21, 1847, took a position at Buena Vista, a mountain pass 7 m. from Saltillo, and awaited the approach of the Mexicans, who made their appearance on the following day, and were signally defeated. (See BUENA VISTA.) Santa Anna retreated to San Luis Potosí, and during the rest of the war the valley of the Rio Grande remained in quiet possession of the Americans. On his return home in November, 1847, "Old Rough and Ready," as his soldiers familiarly called him, was greeted everywhere by the warmest demonstrations of popular applause; and as the time for the presidential election was approaching, his name was at once brought forward for the presidency. He avowed himself "a whig, but not an ultra whig," and in several letters intimated his willingness to accept the nomination provided he could be left untrammelled by partisan pledges, at the same time expressing his distrust of his fitness for the office. In June, 1848, he was nominated by the whig national convention at Philadelphia, the other candidates for the nomination being Mr. Clay, Mr. Webster, and Gen. Scott. Millard Fillmore of New York was nominated for the vice-presidency. Henry Wilson of Massachusetts and a few other delegates, on this result being announced, withdrew from the convention, and subsequently formed the freesoil party on the basis of opposition to the extension of slavery. The democratic national convention had al-

ready nominated Lewis Cass for the presidency; but a powerful section of the New York democracy, familiarly known as barnburners, refused their support to Mr. Cass, partly because of his pro-slavery position. On Aug. 9, 1848, these freesoil democrats assembled in convention at Buffalo, N. Y., together with the freesoil whigs who had rejected the nomination of Gen. Taylor, and the liberty party men who had previously supported James G. Birney. A fusion of these parties was effected on the basis of a platform of which opposition to the extension of slavery was the leading principle, and Martin Van Buren was nominated for president and Charles Francis Adams of Massachusetts for vice president. At the election in November 163 electors were chosen for Taylor and Fillmore to 127 for Cass and Butler. The Van Buren and Adams party did not carry a single elector, their popular vote being about 290,000, while that for Gen. Taylor was about 1,360,000, and that for Cass 1,220,000. Gen. Taylor was inaugurated president on Monday, March 5, 1849, and on the following day appointed as his cabinet John M. Clayton of Delaware, secretary of state; William M. Meredith of Pennsylvania, secretary of the treasury; George W. Crawford of Georgia, secretary of war; William B. Preston of Virginia, secretary of the navy; Thomas Ewing of Ohio, secretary of the interior; Jacob Collamer of Vermont, postmaster general; and Reverdy Johnson of Maryland, attorney general. The democratic party had elected a plurality of the members of congress, and a few freesoil members held the balance of power between the whigs and democrats. A vehement struggle began with regard to the organization of the new territories, the admission of California as a state, and the question of the boundary between Texas and New Mexico, all of these subjects being connected with the question of the extension of slavery. California had applied for admission into the Union with a constitution excluding slavery. There being at this time an equal number of free and slave states in the Union, the proposition to admit California and thus give the free states a preponderance in the senate excited throughout the south the most violent opposition. At the same time New Mexico and Utah, or Deseret, as it was called by the Mormons who occupied it, were without governments. President Taylor in his messages to congress recommended that California should be admitted, and that the other territories should form state constitutions to suit themselves, and should be admitted into the Union with or without slavery as their constitutions might prescribe. These recommendations were not acceptable to the slaveholding leaders, many of whom made open threats of secession. Henry Clay in the senate introduced the compromise measures known by his name, including the recommendations of the president's message. (See CLAY, HENRY.) His propositions were still the subject in one form or another of exciting debates in congress and of earnest discussion among the people, when on the 4th of July, 1850, President Taylor was seized with bilious fever, of which he died on the 9th at the presidential mansion.—Gen. Taylor was of middle stature and stout form, with dark complexion, high forehead, and keen penetrating eyes, with a face more remarkable for intelligence than for elegance, and an expression of much kindness and good nature. It was during this administration that the secession party in the south first manifested itself in considerable force outside of South Carolina. To the schemes of this party Gen. Taylor was sternly opposed.

**TAZEWELL. I.** A S. W. county of Virginia, bordering on West Virginia, and drained by the head streams of Clinch and Holston rivers; area, about 600 sq. m.; pop. in 1870, 10,791, of whom 1,598 were colored. Clinch mountain and other ranges traverse it. The soil of the valleys is very fertile. The chief productions in 1870 were 38,020 bushels of wheat, 155,133 of Indian corn, 69,189 of oats, 9,675 of potatoes, 19,812 lbs. of wool, 95,175 of butter, and 5,301 tons of hay. There were 2,025 horses, 2,562 milch cows, 8,663 other cattle, 9,539 sheep, and 6,651 swine; 3 tanneries, and 3 wool-carding and cloth-dressing establishments. Capital, Tazewell Court House. **II.** A central county of Illinois, bounded N. W. by the Illinois river, intersected by the Mackinaw, and traversed by several railroads; area, 550 sq. m.; pop. in 1870, 27,903. The surface is level, consisting mostly of prairies, and the soil highly fertile. The chief productions in 1870 were 204,827 bushels of wheat, 59,027 of rye, 2,062,053 of Indian corn, 505,841 of oats, 43,210 of barley, 108,984 of potatoes, 29,292 lbs. of wool, 285,323 of butter, and 27,564 tons of hay. There were 10,312 horses, 6,194 milch cows, 10,873 other cattle, 7,591 sheep, and 34,555 swine; 4 manufactories of agricultural implements, 12 of carriages and wagons, 2 of iron castings, 9 of saddlery and harness, 5 of sash, doors, and blinds, 10 flour mills, and 4 distilleries. Capital, Pekin.

**TCHAD,** or **Tsad,** a lake of central Africa, on the borders of Bornoo, Kanem, and Baghirmi, between lat. 12° 30′ and 14° 30′ N., and lon. 13° and 15° 30′ E. It is an irregular triangle, the base of which lies W. S. W. and E. N. E.; length from N. W. to S. E. about 150 m., greatest width about 120 m., area 10,500 sq. m.; but it varies greatly in size in the dry and the rainy season. Its elevation above the level of the sea is about 1,000 ft. It rarely exceeds 15 ft. in depth, and many parts of it are in the dry season a reedy swamp. About two thirds of its area is occupied by islands. Its shores are generally low and flat and covered with rushes and reeds, back of which is fertile ground and rich pasturage; but on the north they rise gradually and are wooded. The S. and W. shores are frequently inundated, and the streets of Kuka, the capital of Bornoo,

which stands about 10 m. from the S. W. shore, are sometimes overflowed. Lake Tchad has two large tributaries, the Komadugu on the west and the Shary on the south, but no known outlet. Dr. Nachtigal says that at some former period the surplus waters were discharged through the Bahr el-Ghazal into an extensive lake 300 m. N. E. The course of this ancient river can still be traced by a fringe of trees, and according to the Arabs water flowed through it for 100 m. during the inundation of 1870. The water of the lake is fresh and sweet; the shallower parts are covered with aquatic plants, and hippopotami, crocodiles, turtles, fish, and water fowl abound. Large herds of antelope feed on its shores, and there are many elephants in the forests on the north. Villages abound on its banks, and the islands in it are densely populated, the central ones by the Buddumas, the eastern by the Kuti, and the northeastern by the Kanembi. The Buddumas are a pagan tribe, distinct from the surrounding Mohammedans. They are well made, active, regular in features, and dark brown or black in complexion. Both sexes are clothed in cotton, and they wear sandals and many ornaments. Cattle and goats are raised by them, and they cultivate maize and cotton.—Lake Tchad was known to Leo Africanus in the 16th century, but the first Europeans who visited it in later times were Denham and Clapperton in 1823. Barth, Overweg, and Vogel explored its vicinity in 1851–'5, Rohlfs in 1866, and Nachtigal in 1870.

**TCHERNIGOV. I.** A S. W. government of Russia, bordering on Mohilev, Smolensk, Orel, Kursk, Poltava, Kiev, and Minsk; area, 20,231 sq. m.; pop. in 1870, 1,659,600. The surface, with the exception of the western portion, is flat, and the soil is particularly fertile. It is well watered, the most important rivers being the Dnieper, which flows on the W. boundary, and its affluent the Desna, which intersects the government. Horses, horned cattle, and sheep are abundant, and the breeds of the first two are particularly good. The manufactures are chiefly articles for domestic use. Much honey, wax, and brandy are produced. **II.** A city, capital of the government, on the Desna, 385 m. S. W. of Moscow; pop. in 1867, 17,096. It is an old town, and has a castle, a beautiful cathedral, several schools, and a large trade.

**TCHIHATCHEFF, Petr,** a Russian traveller, born at Gatchina in 1812. After he had served in the department of foreign affairs and as attaché to the embassy in Constantinople, the government commissioned him to explore the Altai mountains. He has published, besides other works, *Voyage scientifique dans l'Altaï et dans les contrées adjacentes* (Paris, 1846); *L'Asie Mineure: description physique, statistique et archéologique de cette contrée* (8 vols., Paris, 1853–'69); and *Le Bosphore et Constantinople*, of geological interest (1864).

**TCHUKTCHIS. I.** A native tribe of Siberia, inhabiting the E. extremity of the continent of Asia from the 160th meridian to Behring strait. They are apparently akin to the Koriaks, who occupy nearly the same territory, and whose habits and customs are similar. A part of them are settled along the shore, where they support themselves chiefly by killing whales, seals, and walruses; but most of them are nomads, who wander almost constantly with great herds of reindeer, seldom camping more than a week in one place. They are bold, self-reliant, and wholly independent of civilization and government. Their bands are held together only by mutual consent, and have no governing head. In general appearance they are tall, athletic, and vigorous, closely resembling the North American Indians. According to some authorities the Tchuktchis and Koriaks do not number more than 6,000 or 8,000, but the Russian estimates are larger. **II.** A tribe of the Koniaga family in Alaska, otherwise called Aglegmutes, who occupy the coast of Bristol bay from the river Nushagak to lat. 56° N. They live in houses made of slabs, built over an excavation, with a low doorway. They are peaceable, given to labor and trade, and are ingenious in carving and other work, but are sunk in vices and extremely filthy.

**TEA** (Chinese, *tcha*, *cha*, or *tha*), a substance used in making a beverage by infusion, consisting of the dried leaves of one or more species of plants of the old genus *thea*. Bentham and Hooker, who have thoroughly revised the genera, say (*Genera Plantarum*, vol. i., p. 187) that they can find no good characters by which to separate *thea* as a genus distinct from *ca-*

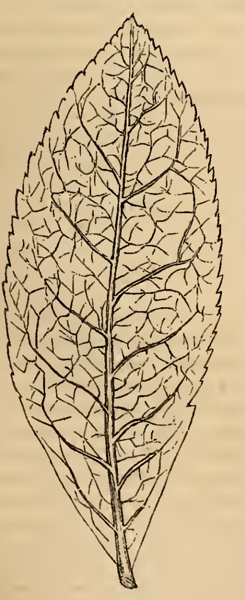
Tea Plant (Camellia thea).

*mellia;* as botanists were mostly agreed that there was but one species of *thea*, the botanical name of the tea plant under this arrangement will be *camellia thea*. The genus is well known from the very general cultivation of *C. Japonica* and other species, especially their double forms, in greenhouses in the northern states, and in the open air in the southern. The tea species differs from any of these in having longer, narrower, thinner, more serrate, and less shiny leaves; its flowers are axillary and nodding, and, though only about an inch across, closely resemble those of a single camellia.

The sepals and petals are usually five, the stamens numerous, a portion forming by their united bases a cup within which are numerous separate stamens; the fruit or pod is usually three-celled, with a single large seed in each cell. The plant in the wild state is a bushy shrub, and sometimes a small tree, but in cultivation is kept dwarf by pruning. Like other plants long in cultivation, tea has produced several marked varieties, which have been described as distinct species. The original country of tea is not known; it has been found in a truly wild state in Assam. In the East it may be cultivated through a wide range, from India to Japan. In this country the plant barely survives the winter at Washington, but a little south of that city it succeeds, and in North Carolina and Georgia bears fruit abundantly. On the Pacific coast, where the climate is especially favorable for broad-leaved evergreens, both native and exotic, the tea plant flourishes much further north than at the east. The time of its first cultivation in China is not known. That its use in the Indies is comparatively recent is inferred from the fact that there is no name for the plant or its product in the Sanskrit. The Portuguese are said to have been the first to import tea into Europe, and were acquainted with it early in the 16th century; early in the 17th it was introduced by the Dutch. Previous to that time it was the custom among European nations to make use of hot infusions of various leaves, notably those of the sage (*salvia*), which at one time had a high reputation, and was regarded as a sort of panacea; its dried leaves were taken to China by the Dutch East India company, to be exchanged for the tea leaf. About the middle of the 17th century a Russian embassy to China brought back to Moscow packages of tea, which were received with much favor; and in 1664 it is recorded that the English East India company made the queen of England what was considered the brilliant present of two pounds of tea. When first introduced into England, tea sold by the pound at £6 to £10; it was known there previous to its direct introduction, having been brought from Holland, but was only used on rare occasions. The first considerable importation was in 1667, when the East India company brought in 4,713 lbs., which was a supply for several years.—Teas are classed as black and green, distinctions not due to their production by different species, but to the age of the leaf when gathered and the methods of preparation; each of these has several subvarieties named from the provinces producing them or the points of exportation, or some peculiarity in the article itself. The Chinese districts which supply the export demand lie between lat. 25° and 31° N. Tea has long been in cultivation in Japan, and since the opening of that country to commerce a large trade in it has grown up. Various parts of India are eminently favorable to the culture; the government of British India has encouraged the introduction of the Chinese plant, and also the cultivation of that found wild in Assam, and large supplies are sent from India to England. In Java and Penang the culture has been established with favorable results. About 1850 the plant was introduced into Brazil, and by the aid of Chinese laborers some tea was produced; but little mention has been made of the results in later years. The experiments in cultivating tea in the United States have been numerous; the most noted was that of Dr. Junius Smith of Greenville, S. C., who gave in the reports of the United States patent office from 1848 to 1859 full accounts of his results; his labors and those of others show that there are localities in the southern states well adapted to the production of excellent tea, and that its success in this country is only a question of the price of labor. In California, where the plant flourishes admirably, an experiment in tea culture has recently been undertaken by a colony of Japanese.—While the many varieties of tea are no doubt produced by the same species, the quality of the product being largely determined by the preparation given to the leaves, it is also much influenced by the soils and situations in which the plants grow. The tea of the hills is different from that of the low lands, and that which receives but little care gives a product inferior to the highly cultivated. The slopes of the hills are preferred, at an elevation depending upon the climate; almost any good arable soil, free from stagnant moisture, will serve for the culture. In China the plant blooms in November, and the seeds are ripe by the next autumn; these, kept in sand till the following spring, are sown in a seed bed, or in rows where the plants are to grow; the plants stand 4 or 5 ft. apart each way, and when about 18 in. high have the leading shoots pinched to induce them to become bushy. The plants yield a small picking in their third year, and attain their maximum yield in the eighth or tenth, after which they deteriorate and give way to young plants; in some localities the land is enriched with litter, sewage, or other fertilizers; the plant, which would naturally form a tree, is, for the convenience of picking, kept pruned down to 5 ft. The quality of the tea depends largely upon the age of the leaves at the time of picking; the younger the leaves the more delicate their flavor, and of course the smaller the yield. The earliest picking, the first of April, consists of the buds and the very youngest leaves; a second gathering, at the end of April or early in May, consists of more developed leaves, and is the most important crop; an inferior quality of leaf is gathered in July, and in some localities another picking of old and poor leaves is made still later. The picker has a basket slung by a cord around his neck, to leave both hands at liberty; he holds the shoot with one hand, and breaks off the blade of the leaf with the other, for, except in the earliest picking of the very

young leaves, no portion of the petiole or leaf stalk must be gathered with the finer kinds of tea. If left in large masses, so that heating or natural fermentation takes place, the leaves are greatly injured. The manipulations to which they are subjected vary greatly, and are often prolonged and repeated in various ways. As each locality has its traditional treatment, supposed to be necessary, the accounts of the process vary greatly; in all, however, the first step is to prevent the fermentation of the leaves, by exposing them in shallow baskets to the sun and air, which withers and slightly dries them. They are then placed in small quantities in a shallow copper or iron pan heated by charcoal or other fuel, and rapidly stirred; at the proper moment they are swept out into other vessels or upon a table, where other workmen rub the leaves between their hands in order to roll them into the form which they finally retain; exposure to the air and a final heating complete the process with some teas, while with others there are several heatings, alternated with airings; the choicer teas are spread out upon a table to be assorted before packing, all imperfectly rolled leaves being removed and the dust and fine fragments sifted out. The chest with its leaden lining being ready, one bare-footed laborer gets into it, and another gradually pours in the leaves, which the first treads down firmly, and as soon as the case is full the leaden cover is soldered down. If the process of drying is completed as rapidly as possible after picking, the tea remains green; but for black tea the process is prolonged, and repeated with long intervals of exposure, sometimes for a whole night, in order that a kind of fermentation may take place. Sometimes two qualities are made from the same picking by sifting the finer leaves from the coarser after they are dried. Apart from the tedious labor of picking the crop leaf by leaf, the necessity for these many small operations before the tea is ready for use will prevent its successful culture in this country, where the cost of labor is already a serious problem in the cultivation of the ordinary farm crops. It requires about 4 lbs. of fresh leaves to make 1 lb. of dried tea, and the yield per acre is from 300 to 400 lbs. Certain districts in China produce either green or black tea exclusively. A third sort, the scented teas, is recognized in commerce. The scenting is generally due to the admixture of certain flowers, and while it is sometimes practised upon choice kinds, it is more frequently employed to give inferior kinds a better flavor; the principal flowers used are those of tea-olive, *olea* (or *osmanthus*) *fragrans* (see Olive), and the chulan (*chloranthus inconspicuus*); but those of the cape jasmine (*Gardenia*) are sometimes employed. The flowers are laid with the leaves under pressure, or are dried with them and afterward sifted out. The classes of tea are subdivided, and names, not always permanent, are given to subvarieties founded upon the size and age at which the leaf is picked. Of the Chinese teas, the principal black sorts are bohea, congou, souchong, caper, oolong, pekoe, and others. Bohea is the coarsest of these, and its importation has greatly fallen off of late years. The highest quality of black tea is pekoe, which consists of the very youngest leaves of the first picking; these, when so young that they are still clothed with down, constitute the flowery pekoe. Among the green teas are twankay, hyson skin, young hyson, hyson, imperial, and gunpowder. The gunpowder in green tea corresponds with the pekoe in black, and like that is from the first gatherings; imperial, hyson, and young hyson are grades made from the second and third pickings, while the inferior light leaves, winnowed from the hysons, make the hyson skin, the chief market for which is found in this country. The brick tea of Thibet is probably the poorest of all; it gets its name from the shape of the blocks into which refuse tea and tea sweepings are made by mixing them with bullock's blood and drying by fire heat; the bricks are wrapped in paper or sewed up in sheep skins, and are rarely exported except as a curiosity. The teas from India have a separate nomenclature. The finer teas, both black and green, are rarely seen in this country; if packed in large parcels, or conveyed in the hold of a ship, a fermentation or change takes place which destroys their quality; a large share of the crop is consumed by the wealthy Chinese, and a portion of it finds its way by overland conveyance to Russia. —Teas are subject to various adulterations in China, and in the countries where they are sold, including the mixing of different qualities, and the coloring and other treatment to improve the looks of inferior kinds. The manipulation of poor teas to give them a finer appearance is carried on in China, and there are establishments in both England and America engaged in the business. The glazing or facing of teas is done with plumbago or black lead, added in fine powder to the tea in a revolving cylinder where the mutual attrition imparts to the leaves a peculiarly smooth and glossy appearance. Green teas, being in this country especially popular (their higher price conveying the idea that they are of better quality), are produced to meet the demand by coloring cheaper black kinds. The principal materials used in coloring are "China clay," or terra alba (largely found in this country and exported), Prussian blue, and turmeric; sometimes gypsum and indigo are used; the coloring matters, mixed in proportions to produce the desired shade, are added to the slightly moistened tea, and the whole agitated until the color becomes evenly distributed and the leaves by rubbing together become glazed. This treatment, with variations in the manipulation, is so general that but very little uncolored green tea is offered for sale. The coloring and facing are readily detected by examining the leaves under the microscope as an opaque

object, when the particles of coloring matter are easily seen; if it is desired to make a further examination as to the materials used, the leaves must be treated with water, and the washings subjected to chemical tests, or be burned, and an analysis made of the ash. The adulteration by mixing a finer tea with a portion of an inferior grade is common; besides this the Chinese prepare what is called "lie tea" for this express use, consisting of the dust which accumulates in the manufacture of tea, and the dust of other leaves, rice husks, &c., made up by the aid of gum into little pellets and colored to resemble tea. Some years ago the annual importation of this stuff into England was half a million pounds annually, all of which was used to mix with teas. The adulteration is readily detected by soaking a portion of tea and examining it with a lens; the true leaf may be unrolled and spread out, while the factitious article will separate into its component fragments. Another adulteration is with exhausted tea leaves; at the Chinese tea houses, which are open day and night, the tea is usually made in a cup, covered with a saucer, and then poured into another cup; large jars stand about the saloons into which the dregs are emptied; these are carefully made over and find their way into commerce. The detection of these when colored is not difficult, but when they are rerolled without coloring, a chemical analysis must be made; it is generally only necessary to test for the amount of tannic acid, which in genuine teas ranges from 20 to 40 per cent., while in exhausted teas it is from 7 to less than 1 per cent., and sometimes completely extracted. The adulteration with other leaves is practised in China, and was formerly to a large extent in England; willow leaves and those of *camellia sasanqua* are much used in China, while in England those of the sloe or wild plum, the hawthorn, elder, plane tree, poplar, and others have been employed. These adulterations and others with false leaves may be readily detected by soaking out and unrolling them; those of the true tea being well known as to their shape, the character of the margin, and especially the serration (the looping together of the principal veins just within the margin being very characteristic), they may be readily picked out from any foreign admixture by the aid of a hand glass.—Tea has been analyzed by different chemists, whose results show much discrepancy, doubtless due to the variable character of the product. The average composition is, in 100 parts: carbohydrates (gum and sugar), 21; fatty matters, 4; albuminoids, 15; tannin, 26·23; vegetable fibre, 20; theine, 2 or 3; mineral substances, 5; water, 5; and an aromatic oil, less than 1. The most important constituent is theine, or, as it is identical with the active principle in coffee, caffeine, a crystallizable substance, soluble in water and having a bitter taste (see CAFFEINE); acting as a feeble base, it is classed among the alkaloids, with the formula $C_{16}H_{10}N_4O_2+H_2O$. Some give the proportion as high as 6 per cent. in the finer green teas, but the average is 2 to 3 per cent. The constituent next in importance is the aromatic oil, as upon this depends the aroma and a large share of the flavor of the tea. The tannin gives the tea its astringency; in the proper making or infusing of tea the object is to extract as much of the theine and aromatic oil and as little of the tannin as possible; when tea is infused too long, or is boiled, the amount of tannin in the infusion is perceived by its marked astringency; more or less of the other constituents are taken up by the water, and give what is called "body" to the tea.—The wealthy Chinese make their tea in the cup. The proper quantity of leaves is placed in the cup, boiling water poured over them, and the cup covered for a time with the saucer; to prevent the leaves from rising to the surface, a perforated bit of silver, or silver filigree work, is placed over them. The poorer Chinese make their tea in a tea pot. In Japan some teas are reduced to a fine powder, which is infused in the cup and stirred before taking, that both the infusion and powder may be swallowed; it is also the custom in Tartary to take the leaves with the liquid. In other countries it is customary to make some addition to the tea: in England and America, sugar and milk or cream; in Russia, lemon juice; and on the continent of Europe it is very common to add a little brandy or other spirit. The quality of the tea (the infusion) is greatly affected by the manner of making it. Those who think that color indicates strength boil the tea, either putting the leaves directly into boiling water, or placing them in cold water and setting the pot upon the fire until the water boils; some practise prolonged infusion, with the same result, a dark-colored liquid, in which the proper flavor is concealed by the amount of tannin extracted; and some add a fragment of soda to increase the color. Connoisseurs in tea usually make it on the table, a caddy containing several kinds of tea and an urn of boiling water being at hand; a portion of boiling water is poured into the tea pot, and when that is thoroughly warmed the water is distributed among the tea cups; then the leaves of one sort (or a



Tea Leaf.

mixture of two or three sorts) are placed in the pot, boiling water poured on, and in a few minutes, the cups being emptied of the water put in to warm them, it is served. The character of the water greatly influences the quality of the tea, it being impossible to make really good tea with hard water. Excess of lime in the water may be corrected by the judicious use of carbonate of soda.—The effects of the habitual use of tea have been much discussed, some regarding them as highly deleterious, while others, on account of the large proportion of nitrogen in theine, have maintained that tea is nutritious, and serves as a substitute for food. The elaborate experiments of Dr. Edward Smith ("Foods," in the "International Scientific Series," New York, 1873) are worthy of study; his results in brief are: that while the amount of nutriment contained in the quantity of tea one consumes is not sufficient to be of use in building up the system or in supplying heat, it has a marked effect upon the vital functions, and particularly stimulates respiration, as shown by the increased amount of carbonic acid thrown off by the lungs after taking it; and that it powerfully promotes the assimilation and transformation of other foods. Excessive use of tea produces wakefulness and increased mental and bodily activity, which is followed by a reaction that brings exhaustion and a corresponding depression. Most of the unpleasant effects of tea are ascribed to the volatile oil; the long continued breathing of air impregnated with this produces illness in the packers of tea, and the tea tasters at the tea marts in China, who are even careful not to swallow the infusion, are obliged in a few years to give up their lucrative positions with shattered constitutions. The Chinese, who drink tea at all times, are careful to use none less than a year old, as in time the oil either evaporates or is so modified that it ceases to be injurious.—There are numerous substitutes for tea in different countries, and widely separated peoples have in use some plant the active principle of which is closely analogous to, if not identical with, that in tea. Besides coffee and chocolate, one of the most important of these beverages is the Paraguay tea. (See MATÉ.) The *khat* of Arabia and Abyssinia, introduced into the Mohammedan parts of Africa, is *catha edulis*, the leaves and small twigs of which possess the properties of tea in an eminent degree. The coca of Peru and Bolivia, though generally chewed, has similar properties, and is sometimes used like tea. (See COCA.) Other plants might be cited. (See also NEW JERSEY TEA.) —The official records of importation into England begin in 1725, in which year there was imported 370,323 lbs.; in the first year of the present century the quantity entered for home consumption was 23,730,150 lbs. Until 1834 the East India company had a monopoly of tea, which paid a heavy duty; but in that year the duty was reduced, and the trade thrown open to all. The imports of tea into Great Britain and Ireland for five years, ending Dec. 31, entered for home consumption only, were: 1869, 998,995 cwt.; 1870, 1,050,202; 1871, 1,102,943; 1872, 1,141,003; 1873, 1,178,760. The value of the total import for the same years, of which one fourth was reëxported, was £10,311,465, £10,097,619, £11,635,644, £12,933,143, and £11,372,595. The imports into the United States for five years, ending June 30, for home consumption, were: 1869–'70, 423,293 cwt.; 1870–'71, 458,615; 1871–'2, 569,741; 1872–'3, 578,707; 1873–'4, 498,318. The total values (in gold) for the respective years were $13,871,546, $17,254,617, $22,943,575, $24,466,170, and $21,212,334.

**TEACHERS' INSTITUTE,** in the United States, an assemblage of the teachers of the public schools of a county or part of a county for the purpose of receiving instruction in the art and methods of teaching, by lectures, conferences, class drills, &c., from experienced teachers. An institute is usually held in each county under the supervision of the county superintendent of schools once a year, sometimes oftener, the sessions lasting from one to two weeks. The instruction is free. This plan was first adopted by Henry Barnard, state superintendent of schools in Connecticut, in 1839. Institutes have been held in New York since 1843, and have been maintained by state appropriations since 1847. They were begun in Massachusetts and Rhode Island in 1845, and soon afterward in many other states. In most of the states they are required by law to be held, and in several the attendance of teachers is obligatory. In some states provision is made for their maintenance by public funds. The instruction in these temporary training schools is necessarily almost wholly oral, and is confined to an explanation and illustration of the best methods of teaching and governing schools. Conferences are held, in which the teachers relate their own experience of particular methods of instruction and discipline.

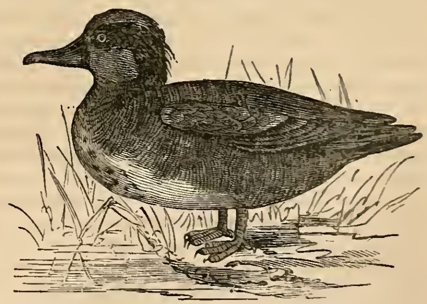
**TEAK,** an East Indian tree, *tectona grandis* (called in Malabar *tecca*), valuable for its timber. It belongs to the *verbenaceæ*, a family which, while its most familiar representatives with us are ornamental herbs and shrubs, includes some important tropical trees. The teak is remarkable for its size and beauty; it grows over 200 ft. high; the elliptical leaves are 12 to 24 in. long, and so rough as to be useful for polishing wood; the small white flowers are fragrant, in terminal panicles, and have the structure common to the family. The tree is found in various parts of India and the adjacent islands, and has been introduced into other British possessions. It is probable that other and closely related species contribute to the supply of commerce. The wood of the teak is one of the most remarkable known on account of its great weight, hardness, and durability, qualities which have caused it to be long used in

the East, not only for temples, but for dwellings. It is most employed in ship building, being practically indestructible by wear or decay, and vessels built of it have lasted 100

Teak (Tectona grandis).

years, to be then only broken up on account of their poor sailing qualities from faulty models. The wood works easily, but on account of the large amount of silex contained in it, the tools employed are quickly worn away; it is brownish, and contains an oil which prevents spikes and other iron work with which it is in contact from rusting, even when the wood is used green. Its weight varies in different localities, from 42 to 52 lbs. to the cubic foot; the teak from Malabar is the heaviest, while that from Burmah and Siam is much lighter; in ship building its great weight largely offsets its durability, and it is therefore now customary to use it only for planking.—Various similar woods are called teak; the African teak was long used in ship building before its origin was known; it is the genus *Oldfieldia*, of the euphorbia family.

**TEAL,** the common name of the small river ducks of the genera *nettion* (Kaup) and *querquedula* (Stephens), called *sarcelles* by the French. In the genus *nettion* the bill is as long as the head, straight, unusually narrow, with sides parallel, as high as broad at the base, the depressed tip with a very narrow nail; wings moderate and pointed, second quill the longest, and the secondaries lengthened and pointed; tail moderate and wedge-shaped; toes united by a full web, the hind one short and slighty lobed. There are about 20 species, distributed all over the globe, though most numerous in the northern hemisphere; they are migratory, commencing their rapid flights in small flocks soon after sunset, resting by day on the surface of fresh water or the reedy shores of rivers and lakes, and feeding principally at night on aquatic insects and worms, seeds, and grains; the nest is made of a large mass of decayed vegetable matter lined with down, and the eggs are eight to ten; they are highly esteemed as game. The European teal was domesticated by the Romans. The green-winged teal (*N. Carolinensis*, Baird) is 14 in. long, 22 to 24 in. in alar extent, and the bill $1\frac{3}{8}$ in.; the head and neck are chestnut, the chin black, and the forehead dusky; around the eyes and on the sides of the head is a broad rich green stripe, passing into a bluish black patch on the nape; below white, with rounded black spots on throat; lower neck, sides, and scapulars finely banded with black and grayish white; speculum on wings broad and rich green; a white crescent in front of bend of wings; under tail coverts black, with a patch of buff white on each side; wing coverts plain olive-gray; in the female the under parts are white, and the upper dark brown with gray edgings. It occurs over the whole of North America, and accidentally in Europe; it migrates principally over the land, breeding from the great lakes to the fur countries; it runs well, is a good swimmer and diver, and a very rapid and graceful flier; having a comparatively long neck, it feeds while swimming, and, being choice in its selection of food, affords a delicious flesh; it is not very shy; the eggs are $1\frac{3}{4}$ by $1\frac{3}{8}$ in., much rounded, dull yellowish with indistinct deeper tints.—In the genus *querquedula* the bill widens a little to the end, which is obtusely rounded, is higher than broad at base, has a wider nail and the lamellæ visible on the sides. There are about half a dozen species in North America, Europe, and Asia,



Green-winged Teal (Nettion Carolinensis).

with habits similar to those of the other genus. The blue-winged teal (*Q. discors*, Steph.) is 16 in. long, 24 or 25 in. in alar extent, with a bill of $1\frac{7}{8}$ in.; the head and neck above are plumbeous gray; top of head black; white crescent in front of eyes; under parts purplish gray, each feather spotted with black; fore part of back brownish with two narrow bands of purplish gray; back behind and tail greenish brown; under tail coverts black; outer webs of some of the scapulars and the wing coverts bright blue; greater coverts tipped with white, with grass-green speculum below them; bill black; in the female the top of the head is brown, chin and throat yellowish white, back brown with paler edgings, under parts whitish

with obscure brown spots, and the same blue and white in the wings as in the male. It is found throughout eastern North America to the Rocky mountains, is abundant about the mouths of the Mississippi in winter, and is less hardy than the green-winged species.

**TEARS,** the limpid, colorless, slightly saline secretion of the lachrymal glands, continually poured out in quantity sufficient to bathe the surface of the eyes, to secure the easy and free motion of the lids, and to wash off any irritating particles from their sensitive membrane. The lachrymal belong to the aggregated glands, or those in which the vesicles or *acini* are arranged in lobules; there is one at the upper, external, and anterior part of each orbit, in a depression of the frontal bone, in relation with the external rectus muscle, resting behind on a fatty areolar tissue; each gland is of the size of a small almond, reddish white, flattened, and enveloped in a fibro-cellular capsule; the secretion is poured out by six or seven trunks opening within the upper lid. At the inner angle of the eyes, in both lids, are two very narrow, always open apertures, the lachrymal *puncta*, in the middle of a slightly prominent tubercle, about 1½ line from the inner junction of the lids; they are opposite each other, the lower turned up and the upper down, and both outward and backward. Through these openings the tears are conveyed by the lachrymal ducts in each lid to the lachrymal sac, at the inner angle of each eye, in the bony groove between the lachrymal bone and the ascending process of the superior maxillary; it is a small membranous sac, opening below into the nasal duct, which conveys the tears into the nose beneath the inferior turbinated bone. At the inner angle of the lids, in front of the globe and behind the lachrymal puncta, is a small reddish tubercle, pyramidal, with the summit turned forward and outward; this is the lachrymal caruncle, and consists of a mass of small mucous follicles, covered by the conjunctiva, which forms in front and to the outside a semilunar fold, called the nictitating membrane; this is rudimentary in man, but remarkably developed in birds. The act of crying, generally accompanying an increased secretion of tears, as far as the movements of respiration are concerned, is very nearly the same as that of laughing, though occasioned by a contrary emotion; the expiratory muscles are in more or less violent convulsive movement, sending out the breath in a series of jerks, accompanied by well known sounds; in children the act is sometimes continued almost to the complete emptying of the chest of air, to the great dismay of parents, but the necessity of breathing is always stronger than the convulsive muscular movements. Moderate excitement, whether of joy, tenderness, or grief, increases greatly the quantity of the tears, though the secretion is checked by violent emotions; in intense grief the tears do not flow, the restoration of the secretion being a sign of moderated sorrow, and itself affording relief by the resumption of nervous action. The sensory, emotional, or instinctive ganglia, situated at the base of the brain, to a certain extent independent of the will, in intense grief become congested, and the flow of tears is the natural method for their relief; hence the danger of cerebral disturbance from long continued tearless grief. Considering their size, there are no other glands which ordinarily can so increase the amount of their secretion as the lachrymal; the quantity is sometimes very great, and very easily stimulated; the shedding of tears is also contagious.—The lachrymal puncta may be closed, causing the tears to flow over the cheeks, for which the remedy is dilatation by fine probes. When the nasal duct is obstructed, the eye is watery and the corresponding nostril dry, the sac forming a small tumor at the side of the nose; the sac also may be inflamed, with pain, tenderness, swelling, and feverish symptoms; this may end in suppuration, and an external opening, constituting lachrymal fistula, requiring the restoration of the obliterated duct by styles of different materials.

**TEASEL** (A. S. *tæsel*, from *tæsan*, to tease), the ripened flower heads of *dipsacus fullonum*, used for raising a nap upon woollen cloths. The genus *dipsacus* (Gr. διψῆν, to thirst, supposed to refer to the cups formed by the united leaves in some species, which hold water) is the representative of a small family, the *dipsaceæ*, which is so closely related to the *compositæ* that in a systematic arrangement it is placed next to that family. Like the composites, the teasel family have their flowers in dense heads, but their anthers are not united and the seeds have albumen. In the teasel itself, of which there are about a dozen old-world species, the plants are biennial or perennial, with coarse, deeply toothed, opposite, rough leaves; the branches are terminated by an oblong head, consisting of small flowers, each in the axil of a bract, which appears as a strong scale when the seeds are ripe. The wild teasel (*D. sylvestris*) is sparingly introduced, and is found in the older states as a roadside weed; it is from 2 to 6 ft. high, and its numerous heads of pale purple flowers, with a large involucre at their base, make it a conspicuous and not inelegant plant; the bracts to the heads terminate in a long straight point; it should be treated as an intruder. The teasel of commerce, or fullers' teasel, though bearing the specific name given above, is generally supposed to have originated from the wild teasel, from which it differs in having a longer head with a shorter involucre; the bracts are much stiffer, and have hooked points. These heads, when ripe, are about 2½ in. long and 1½ in. in diameter, and clothed with regular, strong, sharp, recurved hooks; they are an important article of commerce, and in some countries of cultivation; considerable quantities are produced in England, but the chief supply is from Holland and France. The teasel has now and then been cultivated in

this country; any good soil suits it; the seed is sown in spring, the plants thinned to 18 in. and kept cultivated through the season; the next year the flower heads appear, and earth

Wild Teasel (Dipsacus sylvestris), and Head of Fullers' Teasel.

is thrown against the plants to keep them upright; when the flowers wither, the heads are cut, leaving 8 or 9 in. of stalk attached, and dried in the sun. Their use is to tease or raise a nap upon cloth, and this is done by the hooks, which catch and pull out one end of the wool fibres, near the surface, leaving the other end of the fibre still twisted in the thread. Formerly teasing, or teasling, was done by hand, the heads being fastened in a frame, and drawn over the surface of the cloth by the operator with a frame in each hand; now the work is done by machinery; the teasels, cut lengthwise into halves or quarters, are attached to a wooden cylindrical frame, which revolves, while at the same time the cloth passes beneath it. Much inventive talent has been expended in providing substitutes for teasels, but all have been discarded; for the natural teasel, unlike any artificial substitute, while sufficiently strong to perform the required work, will yield or break in contact with a knot or other obstacle, without injury to the cloth.

**TECHNOLOGY** (Gr. τεχνή, an art, and λόγος, discourse), the systematic knowledge of the theory and practice of the industrial arts. It is divisible into several branches, but chiefly into chemical technology and mechanical technology. Chemical technology embraces those industries which chiefly demand a knowledge of chemistry, such as the manufacture of chemicals, including the various acids and the compounds of soda and potash; the manufacture of soap and candles, glass, and the various kinds of pottery and porcelain; the manufacture of illuminating gas, and the distillation and refining of the waste products of gas works and of crude petroleum; and the distillation and rectification of spirits and the fermentation of wine and beer. Mechanical technology embraces textile manufactures and the mechanic arts in general. In many of the arts a combination of both mechanical and chemical knowledge is required, as in glass making and calico printing. Schools of technology are established independently and also in connection with colleges and universities, not only for the advantage of the general student, but for those who intend to become experts in one or at most a few branches, in which the fundamental principles of the arts are taught, including mathematics, mechanical engineering, natural philosophy, chemistry, and usually mineralogy and geology. In independent institutions other branches are added.

**TECUMSEH**, or **Tecumtha**, a chief of the Shawnee Indians, born near the present town of Springfield, Ohio, about 1768, killed at the battle of the Thames, Oct. 5, 1813. His first prominent appearance was in the attack on Fort Recovery in 1794. About 1805 his brother Elskwatawa set up as a prophet, denouncing the use of liquors, and of all food and manners introduced by the whites. Tecumseh and the prophet then attempted to unite all the western tribes into one nation to resist the whites. They visited the Indians from the lakes to the gulf of Mexico, and soon had a village of 400 Indians gathered at Greenville. Gen. Harrison required them to remove, as it was beyond the Indian limit fixed by treaty. Tecumseh went to Vincennes with 400 warriors to overawe Harrison, and the conference was broken up by his violence. Finding that he had gone too far, he attempted to explain. In 1811, while he was in the south exciting the Creeks and Seminoles to rise by promise of English aid, Harrison marched on the prophet's town to demand that the Indians should return to their various tribes, murderers of whites be surrendered, and plunder given up. The prophet attacked him, and was defeated at Tippecanoe, on the Wabash (Nov. 7). This disconcerted Tecumseh's plans and broke the spell of the prophet's power. When war was declared with England, Tecumseh appeared in Canada with a number of warriors, and refused to meet the American commanders in council. He was in the action against Van Horne on the Raisin, and after being wounded at Maguaga was made a brigadier general in the British forces. He was in command with Proctor at the siege of Fort Meigs, and saved American prisoners from massacre. After the battle of Lake Erie he urged Proctor to engage Harrison when he landed, but accompanied him in his retreat. In the first engagement he was wounded while holding the passage of a stream. With Proctor he selected the battle ground at the Thames, in the S. W. corner of Canada, and he commanded the right wing. Laying aside his sword and uniform in the conviction that he must fall, he put on his hunting dress and

fought desperately till he was killed. Col. R. M. Johnson was said to have shot him; but in reality his death was not for some days known to the Americans.—The life of Tecumseh and of his brother the prophet has been written by Benjamin Drake (12mo, Cincinnati, 1841).

**TEETH**, the organs in vertebrates for the seizure and mastication of food, placed at or near the entrance to the alimentary canal. In adult man there are 32, 16 in each jaw, implanted in sockets, and of an irregular conoid form; in the child, previous to the second dentition, there are only 20. For their development see DENTITION. The number of the teeth increases in the lower animals, being greatest in the cetaceans and marsupials among mammals, and also considerable in many reptiles and fishes. The portion of a tooth above the socket is called the crown, the concealed part the root or fang; between these there is a more or less marked constriction or neck. In vertebrate animals the teeth, like the bones, have for their earthy basis phosphate of lime, mingled with some carbonate of lime and a certain proportion of fluoride of calcium. The latter substance is more abundant in the enamel of the teeth than elsewhere, but everywhere phosphate of lime is the main ingredient upon which the teeth depend for their solidity and firmness.—A tooth is composed of three different tissues, dentine, *crusta petrosa*, and enamel. The dentine, forming the greater part of the body of the tooth, consists of a firm, transparent, nearly homogeneous substratum, composed of about 72 per cent. of calcareous matter and 28 per cent. of organic substance. It is permeated throughout by minute cylindrical channels, called *canaliculi*, about $\frac{1}{12,000}$ of an inch in diameter, which radiate from a central cavity contained in the tooth, called the pulp cavity, toward the external surface of the dentine. During their course the canaliculi branch and divide, often several times in succession, becoming thus very much reduced in size and at the same time increased in number. In the central cavity of the dentine is contained the pulp of the tooth, a soft, vascular, and sensitive papilla, the only portion of the tooth which is supplied with blood vessels and nerves. Undoubtedly the canaliculi of the dentine are either channels for the absorption of nutritious fluids from the pulp, or are filled with soft filaments composed of organic material, by which this absorption is accomplished. The crusta petrosa is a thin layer of bony tissue attached to the outside of the dentine in the fang of the tooth, and serving to connect it, by means of its periosteum, more firmly to the socket. It differs but little from compact bony tissue elsewhere, except that it contains no blood vessels, and is distinguished only by the presence of the irregularly shaped bone corpuscles, which are connected by their radiating filaments with the extremities of the canaliculi of the dentine. The enamel, which covers the surface of the crown of the tooth, is much the hardest of its tissues, containing often over 95 per cent. of calcareous matter. It appears to consist of superimposed layers of calcified epithelium, and is well adapted, by its extreme solidity and almost crystalline texture, to endure the attrition of foreign substances without disintegration.—Three kinds of teeth are distinguishable in mammals, viz., incisors, canines, and molars. The incisors are in the front and median portion of the jaws, and have a simple flattened root and a thin cutting edge, suitable for dividing and collecting food, as in the jaws of the beaver and squirrel and in the lower jaw of the ox. The canines, four in number, are next to the incisors, separated from them by an interval, except in man; the crown is conical, and the root long and simple. They are the so-called eye and stomach teeth in man, and form a striking characteristic and formidable weapons in the carnivora; they are best adapted for securing and tearing living prey. The molar teeth are the most posterior, and have flattened and tuberculous crowns suited for grinding down vegetable food; they are most developed in herbivorous animals; the roots in man are often much bifurcated, rendering extraction difficult.—Teeth are so intimately related to the food and habits of animals, so easily examined, and of such indestructible materials, that they are of the first importance in the classification of animals, both living and fossil. When fully formed they are subject to decay, but have no inherent power of reparation; they may increase by abnormal growth of the crusta petrosa, their most highly organized constituent. For the diseases and the mode of treatment of the teeth, see DENTISTRY.—In fishes the teeth vary from none in the sturgeon and lophobranchs to countless numbers in the pike and the siluroids. They are usually conical, but sometimes flattened or pavement-like, villiform, serrated, and cutting; they may be situated on any of the bones of the oral cavity, on the tongue, and in the pharynx; in most cases they are firmly united to the jaws by continuous ossification, but in some are movable; they are composed of dentine and its modifications, enamel occurring in only a few cases, like the parrot fish (*scarus*); and they are frequently shed and renewed, the germs being developed from the free surface of the buccal membrane. Among reptiles, the whole order of chelonians (tortoises and turtles), and also the toad family among batrachians, are without teeth. In the others these organs are usually simple, and adapted for seizing and holding but not chewing their food; the number is never so small nor so large as in fishes, and is rarely characteristic of species. They are generally conical, sharp, and smooth, and may be placed on any of the bones entering into the structure of the mouth; the base never branches into diverging fangs, and in most is anchylosed in various ways to the bone which bears them, as noticed

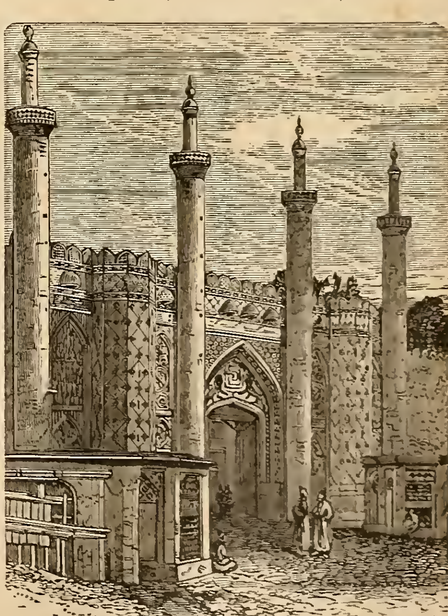
under the different families; dentine and cement are always present, and sometimes enamel, as in the saurian crown. Among mammals, some of the edentates, as ant-eaters and pangolins, have no teeth; in the others they are implanted in sockets, and the molars have two or more roots when they have a limited growth; they are confined to the superior, inferior, and intermaxillary bones, a single row in each. Mammals have been divided by Owen into monophyodonts, or those which generate a single set of teeth, and diphyodonts, or those which generate two sets of teeth; the former include the monotremes, edentates, and carnivorous cetaceans, and the latter all the other orders.—For full details on this subject the reader is referred to the following writings of Prof. Richard Owen: "Odontography" (London, 1840-'45); article "Teeth" in vol. iv. of the "Cyclopædia of Anatomy and Physiology" (1852); and "The Principal Forms of the Skeleton and Teeth," in vol. i. of Orr's "Circle of Sciences" (London; reprinted in Philadelphia, 1854).

**TEGEA,** an ancient city of Greece, in the S. E. part of Arcadia. Its territory was called Tegeatis. It is mentioned in the Iliad. Its early history was marked by a constant war with the Spartans, and about 560 B. C. it fell into their hands. About 500 Tegeans fought at Thermopylæ, and 3,000 at Platæa. Tegea became a member of the Arcadian confederacy after the battle of Leuctra (371), and subsequently of the Ætolian league. After the Roman conquest of Greece it continued to be a place of considerable importance, but about A. D. 400 was totally destroyed by Alaric. Its remains, found near the village of Peali, about 4 m. from Tripolitza, consist of broken columns, friezes, and architraves, and a church in ruins.

**TEGNÉR, Esaias,** a Swedish poet, born at Kirkerud, Wermland, Nov. 13, 1782, died in Wexiö, Nov. 2, 1846. He was the son of a clergyman who had assumed the name of Tegnér after his native village of Tegnaby. He graduated at the university of Lund in 1802, and became teacher of æsthetics and librarian there, and in 1812 professor of Greek. In 1818 he was elected to the academy of sciences and took his degree in divinity, and in 1824 he became bishop of Wexiö. His works include *Svea* (1811); *Nattvards Barnen* ("The Children of the Lord's Supper," 1820), Longfellow's version of which (1841) was regarded by Tegnér as the best of all the translations; *Axel* (1821); and *Frithiofs Saga* (1825), based upon Icelandic sagas. The last has been repeatedly set to music, and translated into many languages. Among the latest versions are Count Leinburg's in German (Frankfort, 1873), Leopold Hamel's in English (London, 1875), and Victor Wilder's in French, set to music by Max Bruch (Paris, 1875). A complete collection of Tegnér's published works was edited and his biography written by his son-in-law Böttiger (7 vols., Stockholm, 1847-'51; new ed., 1871 *et seq.*); and a collection of his posthumous writings has been made by Elof Tegnér (3 vols., 1874). His correspondence has also been recently published. A colossal statue of Tegnér was erected at Lund in 1853.

**TEHAMA,** a N. county of California, lying between the Sierra Nevada and the Coast range, and intersected by the Sacramento river; area, 2,800 sq. m.; pop. in 1870, 3,587, of whom 294 were Chinese. Lassen's peak, in the N. E. corner, is 10,577 ft. high. The E. portion is partly rocky and barren and partly covered with forests of pine. In the west are several well watered and fertile valleys. Some gold is found in the Sierra Nevada, and salt and medicinal springs of great value in the Coast range. The Oregon division of the Central Pacific railroad traverses it. The chief productions in 1870 were 404,722 bushels of wheat, 108,323 of barley, 445,456 lbs. of wool, 68,185 of butter, 33,000 gallons of wine, and 6,549 tons of hay. There were 3,069 horses, 2,157 milch cows, 9,408 other cattle, 130,868 sheep, and 19,459 swine; 3 flour mills, 6 saw mills, and 2 manufactories of gloves and mittens. Capital, Red Bluff.

**TEHERAN,** or **Tehran,** the capital of the kingdom of Persia, and of the province of Irak-Ajemi, 70 m. S. of the Caspian sea and about 210 m. N. of Ispahan, in lat. 35° 41′ N., lon. 51° 23′



Old South Gate.

E.; pop. in winter about 100,000. The town stands in a sandy plain, with mountains to the north and east, and a fertile, well cultivated country to the west. It is built in the form of an irregular square, each side of which measures about a mile, and is enclosed by a deep

dry ditch and a thick mud wall, flanked at intervals with semicircular projections, and pierced by gates which are always guarded, and are closed after sunset. Inside there are many vacant spaces, gardens, and extensive ruins; but the streets are narrow, irregular, unpaved, and filthy. The houses are badly built and mean in appearance. Outside the walls are suburbs of considerable extent, several large caravansaries, and many enclosed gardens. The principal building of the town is the Ark or royal palace, which occupies a large space adjoining the northern wall, and is fortified. The bazaars are wretchedly kept and dirty. One of the mosques is roofed with plates of gold. In summer the climate is unhealthy, and the monarch and about two thirds of the inhabitants encamp on the plains of Sultanieh. On a hill in the neighborhood the shah has a palace and beautiful gardens. Telegraph wires connect Teheran with the Caucasian and Turkish frontiers. Not far from it are the ruins of the ancient Rhages, the capital of Parthia.—Teheran was unimportant until made the capital of Persia by Aga Mohammed Khan about 1796. A treaty of commerce with England was signed here, Oct. 28, 1841.

**TEHUANTEPEC.** **I.** An isthmus of Mexico, lying between the bay of Campeachy on the gulf and the bay of Tehuantepec on the Pacific, and comprising the states of Tabasco and Chiapas and parts of Vera Cruz and Oajaca. Its breadth from bay to bay, at the narrowest place, is 130 m. It is drained by the Coatzacoalcos river, which flows northward, discharging into the bay of Campeachy, and extending three fourths of the width of the isthmus; and by the Tehuantepec river, flowing into the bay of the same name. There are several lakes and lagoons. At one time it was proposed to construct a ship canal across the isthmus, improving the navigation of the Coatzacoalcos for a part of the distance, and surveys were made. (See Canal, vol. iii., p. 690.) **II.** A town of the state of Oajaca, on Tehuantepec river, about 15 m. above its mouth, and 110 m. E. S. E. of Oajaca; pop. about 14,000. The houses are generally of stone. Part of the town is occupied by Indians, who are civilized and industrious. It has salt works and cotton factories, and a considerable pearl fishery in which many of the inhabitants are engaged. Indigo is raised in the vicinity, a purple dye is procured from a shell fish abundant there, and some cochineal is exported. The harbor is shallow, with a dangerous bar at the mouth of the river, and is little frequented.

**TEJADA,** or **Lerdo de Tejada, Sebastian,** president of Mexico, born in Jalapa, April 25, 1825. He was educated in the seminary of Puebla and in the college of San Ildefonso, in the city of Mexico, became rector of the college in 1852, and received the diploma of advocate in 1853. He was a judge of the supreme court from December, 1855, to June 1, 1857, when he became minister of foreign affairs and premier, but resigned in September on account of his support of the new liberal constitution, in opposition to President Comonfort. He was a member and thrice the president of the house of representatives during the sessions of 1861–'2. He opposed the treaty for arranging the English debt, and its failure led to the downfall of the Zamacona cabinet. His influence led to the ratification in December, 1861, of treaties of commerce and of extradition with the United States. He was member of congress in 1862–'3, and followed the government on its removal from Mexico, during the French invasion. On Sept. 2, 1863, he became minister of justice, and on Sept. 11 of foreign affairs. He shared with Juarez the honor of the eventual recovery of the national independence. The presidential term of Juarez expiring on Nov. 30, 1865, Lerdo de Tejada, to avert the excitement of a new election, caused the presidential term to be extended until the termination of the war. After the capture of Maximilian, he was vainly solicited to spare his life. After the return of Juarez to the capital, in July, 1867, Lerdo de Tejada suspended all treaties with those foreign powers which had failed in neutrality toward Mexico, or had joined in the intervention; but he accorded to aliens the same security as to Mexicans. In 1868 he became chief justice of the supreme court. In that capacity, under the constitution, he became president on the death of Juarez in July, 1872; and on Nov. 1 he was almost unanimously elected to that office for the term ending Nov. 30, 1876.

**TELEGRAPH** (Gr. τῆλε, afar, and γράφειν, to write), an apparatus by which intelligence is communicated to a distance. It properly includes the various methods of signalling. The Roman generals, as described by Julius Africanus, spelled words by means of fires of different substances. The North American aborigines made use of regular stations over the western country for such signals; and the Indians of the northwest territory in this way made known the approach of Fremont, as he passed through their regions. Polybius describes two modes of telegraphing by means of torches; and Bishop Wilkins, after giving an account of this in his book entitled "Mercury, or the Secret and Swift Messenger," describes a method of conversing at a distance with three lights or torches at night, which may be so used as to indicate the 24 necessary letters of the alphabet, these being divided into three classes of eight letters each, which are severally designated by one, two, or three torches, and the number of the letter by the number of times the torches are elevated or displayed. Another method was also proposed by Bishop Wilkins, in which intelligible signals were conveyed by means of two lights attached to long poles; and for long distances he suggested the use of the then newly invented telescope. A variety of systems of telegraphic signals were brought into notice by different inventors in the 17th and 18th centuries, one

of the earliest of which is that of Dr. Robert Hooke described in the "Philosophical Transactions" for 1684. It consisted of 24 symbols formed of blocks of wood, representing alphabetic characters, and six more formed of curved lines to be used as arbitrary signals. These were to be exposed in succession in an elevated frame at some conspicuous point, and, being observed at another station, were to be there repeated and sent forward to the next, and so on. At night torches or other lights were to be substituted for the wooden figures. The first working telegraph of much importance was that known as Chappe's, invented in 1792, which was brought into use during the wars of the French revolution. At the top of a tall post was attached a cross bar upon a pivot, so that it could be easily turned from a horizontal to an inclined position. Each end of this cross bar carried a short arm, which could also be turned upon its pivot so as to stand in any position in relation to the bar. The movements were made by means of ropes which passed through the bar and down the post. This apparatus admitted of 256 distinct signals; but M. Chappe limited its use in great part to 16 signals, each one of which represented a letter of the abbreviated alphabet he had constructed. Chappe's method has been generally adopted, all the alleged improvements in it being of minor importance. Mr. R. Lovell Edgeworth about the same time brought before the public his plan of a telegraph, or as he called it telelograph or tellograph, by which the signals represented numbers, the meaning of which would be found in the dictionary prepared for this system. The signals were made by means of four pieces of wood, each one in the form of a long isosceles triangle, placed near together, each supported upon a pivot round which it could be turned in any direction. The movements of each were limited to eight, and indicated the first seven numerals and zero. The first triangle or pointer represented units, the second tens, the third hundreds, and the fourth thousands, so that any number might be expressed that did not contain the figure 8 or 9. The admiralty telegraph proposed by Lord G. Murray was used in England from 1795 to 1816, when it gave place to that known as the semaphore (Gr. σῆμα, a sign, and φέρειν, to carry), which the French had adopted in 1803. This consisted of six conspicuous boards or shutters set in a frame, each of which could be turned upon its axis so as to present either its edge or its broad surface to the next station. The movements represented figures, and a series of numbers was indicated by their combinations. Some of these stood for the letters of the alphabet, and the others for arbitrary signals. The French semaphore (also known as signal posts) consisted of three or more arms attached by pivots to an upright post, admitting of motion in any direction, and indicating by their various positions either figures or letters. Many modifications of this apparatus were used. For telegraphic communication at sea, flags of various colors have long been used. (See Signals, Naval.) In 1835 Gauss proposed to employ a small heliotrope or mirror for reflecting rays of light from the sun or an artificial source as a means of communicating signals. With a mirror so small that it may be carried in the waistcoat pocket, flashes of light may be clearly perceived for 12 m. or more, and, the mirror being gently moved on some established system, the appearance and disappearance of the flashes may indicate letters or words. By this device time can be saved, telescopes dispensed with, and the signals seen only by those for whom they are intended. Francis Galton, the African traveller, proposed a plan similar to this at a meeting of the royal geographical society, and described an optical arrangement he had devised by which the operator may know if the mirror is directed aright. Among the later publications upon the telegraphs adopted previous to the electric telegraph, are papers in the "Journal of the Society of Arts," vols. xxvi., xxxiv., xxxv., and xxxvi.; "A Treatise explanatory of a new System of Naval, Military, and Political Telegraphic Communications," &c., by John Macdonald (London, 1817); "Description of the Universal Telegraph for Day and Night Signals," by C. W. Pasley (London, 1823); and Edgeworth's "Essay on the Art of conveying Secret and Swift Intelligence," in the "Transactions of the Royal Irish Academy," vol. vi. The advantage of all these methods of telegraphing, which may be described in general as the optical method, is, that they employ nature's great highways, which cost nothing; the disadvantages are, that the signals cannot record themselves, but require the constant attention of an observer, and can be used only for moderate distances and in favorable weather. Moreover, the expense is great compared with the meagre intelligence which is communicated. The semaphore between London and Portsmouth, 72 m., which could be used less than one fifth of the time, required an annual expenditure of £3,403.—Electric Telegraph. The various kinds of electric telegraphs may be classified in two ways. In the first place, they differ in regard to the source from which the electricity is derived. In the present state of science, five independent sources of electricity are recognized: 1, friction; 2, chemical action; 3, magnetic induction; 4, heat; 5, physiological actions. The difficulty of insulation unfits frictional electricity for this work, except at short distances and in dry air. The fourth and fifth sources must be rejected as insufficient for practical use. Successful telegraphs must rely on electricity produced by chemical action or magnetic induction. In the second place, electric telegraphs may be classified according to that one of the five special effects of electricity which is selected as the means of delivering the message when

it arrives: 1. The statical attractions and repulsions would be impracticable except with frictional electricity. 2. The chemical effect of electricity is capable of making a visible sign and also a permanent record. 3. The magnetic effect is able to make a visible sign, as in the needle telegraph; it can also prick out its message in an artificial alphabet, or even print it in ordinary type. 4. The physiological effect can furnish a signal which may be felt. 5. The luminous and the calorific effects can be used for visible signals, but they cannot write or print. Of the manifold attempts at electric telegraphs, the best are now known to be those which employ the chemical or the magnetic effects. As the chemical telegraph works silently, an electro-magnet is required even in this case to attract the attention of the person who is to receive the message. The electro-magnetic telegraph can address the eye or the ear, and can also write or print.—Attempts have been made to prove that the electric telegraph was foreshadowed more than two centuries ago. Prof. Mannoir puts in a claim for Dr. Odier on account of a letter which he wrote in 1773. But Addison, in No. 241 of the "Spectator," written in 1711, quotes from the *Prolusiones Academicæ* of Strada a description of essentially the same arrangement as that proposed by Dr. Odier. Moreover, Schwenter in 1636 had the same idea, but borrowed from a still earlier writer. How chimerical the scheme was in all these cases, and how unworthy of being regarded as an anticipation of the real discovery, will appear from the following brief description of the project: A magnetized needle is free to move over a graduated dial, the marks being the letters of the alphabet. One of these instruments stands in one place, and another in a remote city. If the needle of one is placed upon a particular letter, the needle of the other will move to the same letter by virtue of the magnetic forces. Du Fay, Winckler, Lemonnier, Gray, and Desaguliers made experiments, which showed that the effect of electricity could be transmitted to a distance. The discovery made by Dr. Watson in 1747, that electricity would force its way through considerable lengths of wire, and that earth and water could take the place of wire in completing the circuit, furnishes the first facts of any significance in the history of the electric telegraph. He transmitted shocks across the Thames and the New river, in one instance at Shooter's Hill the circuit being composed of about 2 m. of wire and 2 m. of the earth; and he supported his wires upon posts. Franklin made similar experiments across the Schuylkill river in 1748, and De Luc afterward on the lake of Geneva. Signals were communicated by means of the electric shock from one apartment to another by Lesage at Geneva in 1774, and by Lomond in France in 1787 by the divergence of pith balls on some concerted plan; and in 1794 Reizen of Germany employed the electric spark for telegraphing, making use of interrupted strips of tin foil, so arranged that the form of the letter or figure was exhibited by the sparks. He employed 36 wires from one station to another, each one of them communicating with one of the letters or figures, and each one connecting with a return wire, thus making 72 in all. This plan is described in vol. ix. of Voigt's *Magazin*. Cavallo in his "Treatise on Electricity" (1795) suggests the explosion of gunpowder to call attention, and then the transmission of signals by a succession of sparks at intervals and in numbers according to the system agreed upon. Don Francisco Salvá of Madrid and Sr. Betancourt constructed similar telegraphs at Madrid in 1797 and 1798, one of them extending between Madrid and Aranjuez, about 26 m. (Voigt's *Magazin*, vol. xi.) Salvá communicated his plans to the royal academy of sciences at Barcelona, and according to the journals of 1797 they were highly commended by the minister of state. Salvá appears to have had a clear idea of the practicability of electric communication even beneath the sea, and in the last of his memoirs he proposed to substitute the voltaic pile for the electrical machine. Other attempts to employ frictional electricity were made by Francis Ronalds at Hammersmith, England, in 1816, on a line of 8 m.; and in 1827 by Harrison G. Dyar at the race course on Long Island, N. Y., on a line of 2 m. The latter made use of iron wire, glass insulators, and wooden posts, and employed for signalling the chemical power of the electric current to change the color of litmus paper. Ronalds introduced the plan of employing a clock at each of the two stations, both of them running together exactly, and each bringing into view one after the other the letters of the alphabet arranged upon a disk which revolved behind a screen with an opening for one letter. Each clock was provided with two pith balls connected with an electrical machine at the other station; and their divergence called the attention of the other operator to the letter then in view. The voltaic pile, discovered in 1800, furnished in its continuous current a more promising agent for transmitting intelligence than the sudden and transient discharge of the friction machine. Sömmering began his experiments in 1809, and devised a plan of telegraphing which was as perfect as was practicable at that time. He used 35 wires, terminating in gold points, set up vertically on a horizontal line at the bottom of a glass reservoir of water. In the other direction these wires, brought together in a tube, extended to the other station, where they again diverged, terminating in brass plates attached to a horizontal wooden bar. The plates at one end and the points at the other were marked with corresponding letters, and whenever a momentary current was sent through any two of the plates, hydrogen was evolved at one of the gold points and oxygen at

another, and thus two letters were indicated. Sömmering found that the addition of 2,000 ft. of wire produced little or no sensible additional resistance, and that voltaic action was instantaneously developed at least for the distance of 3,000 ft. In 1810 Prof. Coxe of Pennsylvania suggested a method of telegraphing by means of the chemical effect of electricity. Schweigger described an improvement upon Sömmering's arrangement, by which all the wires could be dispensed with except two. The batteries then known were insufficient for the transmission of currents through great distances, and besides were deficient in sustaining power; therefore no further progress was made in perfecting the electric telegraph until the principles of electro-magnetism had been developed. (See Electro-Magnetism.) In 1819 Oersted discovered the power which the current possesses of deflecting a magnetized needle out of the magnetic meridian. In 1820 Schweigger added the multiplier. This was followed by Arago's discovery in the same year that a steel rod was magnetized when placed across a wire which was carrying a current. Ampère immediately substituted a helix for a straight wire. In 1825 Sturgeon used soft iron in place of steel, and the electro-magnet was born. Between 1828 and 1830 Prof. Henry of Princeton, N. J., made great improvements in the construction of electro-magnets by covering the wire and winding the coil compactly. In 1831 he devised an instrument which is essentially the same as the Morse register. Moreover, Ohm in 1827, and Fechner in 1831, published the results of their theoretical investigations into the laws of the voltaic current, which shed a flood of light on the subject of telegraphing at long distances. If these investigations had but little practical effect, it was because they were not generally known until the same results had been at a later day worked out empirically. Equally important was the invention of the constant battery by Daniell in 1836, and of various other constant batteries which have been contrived since that time. The discovery of magneto-electricity by Faraday in 1831, and the introduction at a much later date of the induction coil, supplied constant sources of intense electricity adapted to the telegraph. Within a year after Oersted's discovery Ampère pointed out its applicability to telegraphic signals. His plan contemplated at least 30 needles and 60 independent wires. In 1828 Ritchie gave an experimental illustration of such a device before the royal institution of London. In 1829 Fechner had a similar project for uniting Leipsic and Dresden by means of 24 sets of underground wires. In 1832 Schilling exhibited to the emperor Nicholas of Russia a needle telegraph in operation on a small scale. He used a needle provided with a multiplier of insulated wire for each letter or number to be indicated. The several wires were brought together beyond the multipliers into one cord, and thence passed to the first station. Eventually he succeeded in reducing the number of needles to one. He also introduced an alarum at the commencement of the passage of the current by causing a solid body to fall, on the same principle as had been already recommended by Prof. Henry in his lectures. These experiments were interrupted by his death, and the steps made were lost, without even a very accurate account of the results being preserved. The next experiments of importance were those of Gauss and Weber of Göttingen in 1833 and 1834. They employed first voltaic electricity excited by numerous small elements, and afterward a magneto-electric machine to transmit signals from 9,000 to 15,000 ft. They caused a magnetic bar to be deflected to one side or the other, and interpreted its repeated movements into the letters of the alphabet. The vibrations of the magnet were checked by a damper, or by the use of currents alternating in direction. This telegraph was of practical value in comparing clocks and for other purposes. Gauss stimulated his pupil Steinheil to a bolder undertaking, in which he was assisted by the Bavarian government. Steinheil's telegraph, completed in 1837, extended 12 m., employed but a single wire, and made use of the earth to complete the circuit. The signals were sounds produced upon a series of bells of different tones, which soon became intelligible to a cultivated ear; and the same deflections of the needle that caused the sounds were also made to trace with ink lines and dots upon a ribbon of paper moved at a uniform rate, the alphabet having a remote resemblance to that invented by Swaim in 1829. Steinheil used a magneto-electric machine, but with the magnets stationary and the multiplying coils revolving close to them.—Morse's telegraph, which is generally recognized in all parts of the world as the most efficient and simple, was first publicly exhibited in the university of New York in 1837. It had been gradually brought to a working condition by experiments and contrivances devised by the inventor since 1832, with the assistance of L. D. Gale and George and Alfred Vail. In October, 1837, Prof. Morse filed a caveat in the patent office to secure his invention; and he obtained the patent in 1840, covering the improvements he had in the mean time made in the apparatus. The telegraph was first brought into practical use, May 27, 1844, between Washington and Baltimore. An insulated wire buried in a lead pipe underground was first tried, and failing was replaced with one on posts. The power was derived from a voltaic battery, and an electro-magnet was employed at the receiving station for developing its effects. When the current flowed, this magnet attracted an armature, by which, according to the duration of the current, dots or lines were marked upon a moving slip of paper with a pen or pencil. The apparatus furnished a simple and effective means of recording signals, which by the needle tele-

graph were only evanescent. The apparatus was improved by the substitution of a sharp point for the pen or pencil, which is attached to one end of a lever, at the other end of which is the movable armature. The following illustrations exhibit the several parts of the Morse instrument as now in use. The key, fig. 1, consists of a brass lever L, swung on pivots, and having on one end a button. When this button is pressed down, two platinum wires, *a* and *b*, are brought into contact, thus closing the circuit; when the pressure is removed, a spring lifts the lever, separates the wires, and breaks the circuit. When the message is sent the operator permanently closes

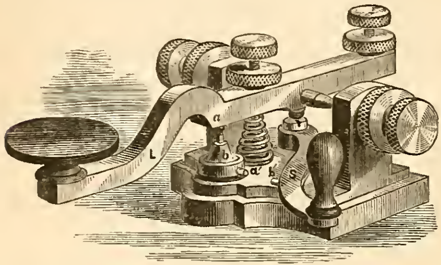


Fig. 1.—Key.

the circuit by springing to the left the lever S, which brings into contact the duplicate platinum wires *a′ b′*. The relay magnet, fig. 2, is an electro-magnet wound with a long fine wire, which is introduced into the main line and becomes a part of the great conductor from city to city. When the key breaks and closes the circuit, the relay receives the voltaic

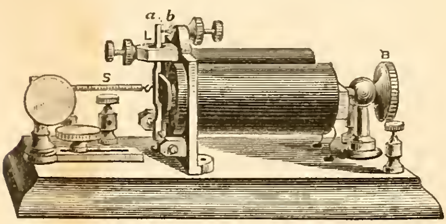

Fig. 2.—Relay.

current and becomes magnetized and demagnetized. The delicately poised lever L, having the armature of the magnet attached to it, vibrates forward and backward, bringing together the two platinum wires *a b*, and thus breaking and closing a secondary or local circuit, embracing a local battery and a strong electro-magnet. This magnet performs various work, such as embossing or printing paper, or the liberation of machinery for the production of sounds. A screw B is used to move the magnet coils backward and forward so as to adjust the general magnetic power, and a spring S retracts the armature after magnetic attraction has drawn it forward. The sounder, fig. 3, is an electro-magnet used in the local circuit. The armature, A, is attracted by the electro-magnet M, causing the lever L to vibrate between the screws S S, which are so adjusted as to limit the vibrations. The backward and

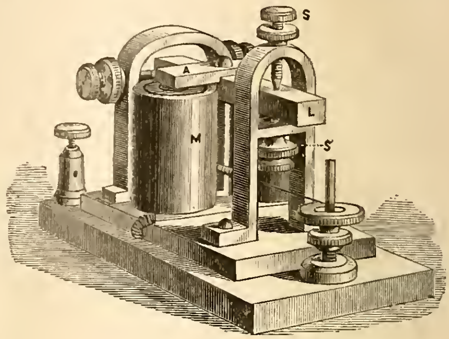

Fig. 3.—Sounder.

forward blows thus given, some of which are short and some long, correspond to the dots and dashes of the Morse alphabet. This is now more generally used than the Morse register or recording instrument, as experience has proved that fewer errors are made by the ear than by the eye. The Morse register, fig. 4, has also the electro-magnet M, the armature A, the lever L, and the adjusting screws S S; but instead of producing sounds merely, the lever L embosses on a fillet of paper P dots and dashes in precise accordance with the movements of the key and relay. The paper is carried between two rollers, moved by clockwork, in one of which is a groove, into which the steel point presses the paper. When successive blows are struck on the key, closing and opening the circuit quickly, corresponding dots appear on the paper; but if the key be pressed down for a longer or shorter time, keeping the circuit closed, a continuous line of any desired length may be produced on the paper. The signs for the letters of the English alphabet

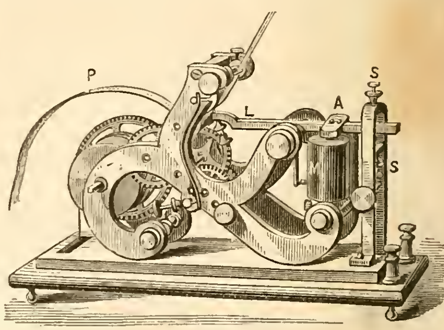

Fig. 4.—Register.

(which are variously modified to adapt them to other alphabets), and for the numerals and punctuation marks, are as follows, those most used being the simplest:

The slightness of the difference, which cannot be avoided, between some of the signs, as in the C and S, I and O, L and T, &c., exposes to mistakes, which in case of writing in cipher cannot be corrected, and not always when the message is perfectly understood by the operator who sends it. Thus a merchant telegraphed from New Orleans to his correspondent in New York to protect a certain bill of exchange; the word "protect" was read as "protest," and involved serious consequences.—What is known as the English telegraph is the result of the investigations and inventions of William F. Cooke, whose attention was directed to this subject in March, 1836, when a student at Heidelberg, by witnessing an experiment performed by Prof. Möncke of causing the deflection of a magnetic needle by the electric current. In July of that year Cooke produced an experimental instrument, which he not long afterward took to England and sought to introduce on the Liverpool and Manchester railway. He there became associated with Prof. Wheatstone, and the two united their labors to perfect the instrument. The first patent for an electric telegraph was issued to them on June 12, 1837. They employed five magnetic needles and coils, and either five or six wires, with a peculiar keyboard invented by Wheatstone, upon which were arranged the letters, and these were designated in turn as any two of the needles arranged across the centre of the board pointed to one and another of them. The apparatus underwent various modifications in the hands of its inventors, and was much simplified by the use of only two needles, and finally of only one, different letters being designated by the deflection of the needle to the right or to the left one or more times in either or both directions. The swinging of the needle is checked by small pins fixed on the dial, so that the motions are rendered precise and clear. In this single-needle telegraph, each instrument has its own battery and wire. In case of accident to the wire of one instrument, that of the other serves to keep up the communication. With each apparatus was formerly connected an alarum bell, the clapper of which was moved by a weight or spring connected with clockwork, which was released by means of an electro-magnet. This is now generally abandoned, the sound made by the click of the needle against the pins being found sufficient. Wheatstone introduced one very important feature in his electric telegraph, which is a local battery for working the alarum. It is brought into action by the deflection of a magnetic needle, the ends of which are thus placed in contact with the two wires of the second battery, and so close its circuit. The double-needle telegraph is often used upon the railways of Great Britain, each needle having its own wire. The different signs are made by the movements of one or both of the needles. The needles upon the dial are moved by the messages sent as well as by those received, so that each operator may see the signals he makes. In these needle telegraphs no record is made of the message by the instrument itself; the operator observes the signs, and notes them upon paper as they succeed each other. With the English double-needle telegraph, employing two wires and two batteries and other apparatus at each station, an expert operator can send as many as 150 letters a minute; but this is more than can be correctly read, the limit of which is about 100 letters a minute, and in actual practice the number is somewhat less than this, or from 17 to 24 words a minute. Operators accustomed to the work do not require the lettered dial for reading the movements of the needle.—Of the numerous telegraphic inventions that soon succeeded those already named, Alexander Bain's are particularly worthy of notice. He was engaged in England as early as 1840 in producing a printing telegraph, and in 1846 patented what is known as an electro-chemical and registering telegraph, the principle of which had been first applied to the purpose by Dyar in this country in 1827, and by Edward Davy in England in 1838. Mr. Bain brought his new telegraph to the United States in 1849, and it was brought into use on several important lines; but after a lawsuit involving chiefly the use of the local circuit, the Morse interests forced a consolidation, and the Bain system had afterward but a limited use. The local circuit gave to the Morse system its great importance and value. On long lines of telegraph the wire offers such resistance to the passage of the current that its presence is detected only by delicate instruments, which however are capable of vibrating levers whose office is to open and close secondary or local circuits; and these circuits being short, unlimited magnetic power may be obtained for recording or producing sounds. The Bain telegraph was essentially the same as that now called the "automatic." The revival of the system is due to recent discoveries in the arrangement of circuits, by which the rapidity of recorded electrical impulses through very long conductors has been made almost infinite. For recording, dots and lines are produced on chemically prepared paper, which is moved while damp at a uniform rate over a metallic roller; a fine wire, through which the line current passes, rests on the surface of the

paper and blackens it by decomposing the chemical. The current was formerly sent over the line by the key, as in the Morse system; but to call attention a bell was used, and this usually required the local circuit. Mr. Bain had at this time fully developed a plan for transmitting signals with a rapidity far greater than could be effected with the key, and this plan is the same as that now used in the revived system. In place of the key a fillet of paper was punched with lines and dots representing a message. This was passed over a metallic roller with great speed, and a fine wire which rested on the paper entered each hole as it moved and completed the circuit through the roller. The receiving machine was made to run at a speed corresponding with that of the transmitting machine, and the perforated dots and dashes were reproduced in blackened dots and dashes. The advantage of this system lies in the transmission of long messages, which are received and prepared by several operators, at great speed. Until recently this speed could be obtained only on short circuits, the marks on long circuits running into each other and becoming illegible. Later improvements have enabled messages to be sent from Brussels to Ostend and back at the rate of 450 words a minute; and the American instruments have sent between Washington and New York 5,250 letters a minute, requiring 10 perforators to feed it, 10 copyists, and two operators.—*Facsimile Telegraphs.* Electric copying or facsimile telegraphs are modifications of the automatic chemical. They originated with F. C. Bakewell of England in 1850, and have been improved by Caselli, Bonelli, and others. In them the message is written with a pen dipped in varnish upon a sheet of tin foil, which is then laid around a metallic cylinder, corresponding precisely in its size, rate of revolution, and longitudinal movement, with another cylinder at the receiving station, which is covered with chemically prepared paper and provided with a pointer like that of the Bain chemical telegraph. These cylinders being set in motion at the same instant, the point of the registering apparatus makes a continuous colored line, running round the cylinder in a close spiral so long as the metal style at the other station presses upon the tin foil; but as this passes over the lines of varnish a break in the circuit occurs, causing an interruption of the colored line at the other station. The blank spaces thus produced will be found when the lines have been drawn over the whole paper to be a facsimile of those written in varnish upon the tin foil. The lines, though drawn as spirals upon the cylinder, appear as parallels when the paper is taken off. About 10 revolutions of the cylinder, making as many parallel lines, are sufficient to complete one line of writing; a cylinder 6 in. in diameter affords sufficient length for about 100 letters of the alphabet in one line; and as the rate of revolution is not less than 30 in a minute, 300 letters or more may be transmitted in this period. A message in cipher can be sent by this method without risk of error, and even invisible messages written in colorless varnish may be received and impressed in invisible characters upon prepared paper, to be afterward brought out by chemical means; thus, if the paper be moistened with diluted acid alone, no visible mark is left upon it until it is brushed over with a solution of prussiate of potash, when the lines appear in their blue color. Great improvements in the autographic telegraph have been made by Caselli, who has succeeded in making dark letters upon a white ground. His instruments have been used on some of the French lines since 1862.—*Printing Telegraphs.* Royal E. House, of Vermont, received a patent in 1848 for an admirable long-line printing apparatus, which was first used in 1847, sending messages in Roman capitals between Cincinnati and Jeffersonville, Ind., 150 m. The necessity of avoiding the peculiar features upon which other telegraphic systems were established, in order to give to it a distinctive and patentable character, added greatly to the difficulties of the undertaking, which after nearly six years of labor were overcome by the ingenuity and perseverance of Mr. House. The apparatus is very complicated, and little more can be attempted than to state its great powers of execution and its perfect accuracy. The mechanical movements of this machine are set in action by hand labor applied to a crank, which works an air pump for supplying a current of condensed air, which under the control of the electric current carries forward the movements of the composing and printing apparatus, so that each letter may be printed at the exact instant that it is struck upon the keyboard of the instrument. This keyboard, which resembles that of a piano, is connected with the electric current, and as the keys are struck the circuit is opened and closed with the movements of a circuit wheel which controls the movements of the type wheel. A complete revolution of the circuit wheel, coming round again to the same letter, breaks and closes the circuit 28 times, and other letters a less number according to their arrangement on the type wheel. The printing apparatus is quite distinct from the circuit, but the composing apparatus forms a part of it. The impression of the letter is produced by a blackened ribbon being pressed against the paper by the type. From the voltaic battery of one station, the current passes along the wire to the next station, then through the coil of an axial magnet to the insulated iron frame of the composing machine, and thence to a circuit wheel revolving in this frame. Through a spring that rubs on the edge of this wheel it passes into the return wire, and through another battery back to the first station to pursue the same course through the composing machine and magnet there, and all others upon the line. In sending a message, the operator sets his machine in motion and

gives a signal by breaks of the circuit, repeated a different number of times for different offices on the same wire. As this is heard by the operator at the receiving station, he sets his machine in motion, and the type wheel at its starting point, and signals back that he is ready. No further attention is required on his part, while the machine goes on, printing the communication in Roman capitals upon the long strip of paper regularly supplied to the type wheel. From 250 to 260 letters as a maximum can be accurately printed every minute, and over 3,000 words an hour of press news, partly abbreviated, have been sent over the wires with a single instrument. The House printer was the parent of many others working on the same principle, the "step by step" movement, in which each break or close of circuit allows a tooth of an escape wheel to pass; a type wheel being on the same shaft, a new letter appears for each tooth that escapes.—On May 20, 1856, Mr. Hughes patented a telegraph, in which the feat of printing a letter with every impulse or wave of the electric current was accomplished. In the other telegraphs, as already described, several impulses produced by successive makes or breaks of the circuit are required to form a single letter; this in House's telegraph varies up to 14 breaks, the maximum required for repeating the same letter, and averages about 7 impulses; and in the Morse system the average is about 3½ impulses, those which make lines being of longer duration than those which make dots. The saving of time thus effected by the Hughes instrument is of great importance, especially on long lines in which an appreciable amount of time is expended in the passage of the current. In long lines of submarine telegraphs, as will be noticed below, a greatly increased resistance is experienced in charging the wires with the electric current, and the impulses necessarily succeed each other with extreme slowness and diminution of force. The type wheel in the Hughes system is provided with 28 types; it is kept in rapid revolution during the whole time of operating, and is so perfect in its movement that, though the revolutions may be from 100 to 140 a minute, the variations of two machines at different stations do not exceed $\frac{1}{20}$ of a second in several hours. At the instant one of the 28 keys is depressed, the current entering the magnet at the distant station causes the strip of paper to be brought against the type opposite to it at the time, and receive the impression in ink while this is rapidly carried round with the wheel. The operator can send an average of two impulses with each revolution of the type wheel, thus making the capacity of the instrument 200 letters or 40 words a minute, and the maximum is much above this. The regulators or governors of the clockwork which carries the type wheels at the different stations are springs of the same musical tone, which consequently vibrate the same number of times a second, and which control by their vibrations the escapement of the apparatus. The power of the electric current required is reduced in a wonderful degree by the combination of the natural magnet and the electro-magnet, making only so much electricity necessary as will neutralize the magnetism in the natural magnet by causing magnetism of an opposite polarity to be created in the poles of the electro-magnet. This extreme delicacy, however, renders the telegraph liable to be interrupted by atmospheric electricity, such as is developed previous to and during the continuance of the aurora borealis. It is asserted that this instrument can work upon a longer line without the aid of repeaters than any other, and this with an extraordinarily low battery power.—In the winter of 1858 a new instrument was perfected by G. M. Phelps of Troy, combining the most valuable portions of both the House and Hughes patents, which has been introduced with great success on nearly all the lines formerly using those inventions. This has been termed the "combination" instrument, and has the advantage of being able to work through a much longer circuit than the House machine, with a smaller battery, as well as of being much simpler. The keyboard and transmitting machinery of this instrument are precisely like those of Hughes, as is also the printing apparatus, with the exception of the electro-magnet, which is of the ordinary form, and operates upon the type wheel through the medium of compressed air as in the House machine. The vibrating spring used by Hughes as a governor is superseded in the combination instrument by a most ingenious electro-magnetic governor, the invention of Mr. Phelps. It consists of a hollow iron drum, geared to the transmitting cylinder and type wheel of the instrument and moving with them, but much faster. If the machinery has a tendency to revolve too rapidly, the increased centrifugal force, acting upon a detached section of the drum, actuates a series of levers inside, by which a spring is raised, closing the circuit of a local battery through an electro-magnet. A friction brake, which is applied to the revolving drum by the attraction of this magnet, instantly reduces the speed to the required limits, when the local circuit is again broken. The combination instrument is considered the most perfect printing telegraph for long lines yet produced. The Anders printing telegraph, patented in 1871, and worked by magneto-electricity, is designed for private lines, though capable of operating over distances of 45 m. —*Dial Telegraphs.* In these instruments the step by step movement is generally employed, but the escape wheel does not carry a type wheel, nor do the printing accessories enter into their construction. A light needle is carried around with the escape wheel and points at the successive letters. They are thus visual and not recording telegraphs. In England, the "Magnetic Telegraph Company" employed

magneto-electricity, thus dispensing with voltaic batteries, the use of which involves much care and expense. The apparatus is remarkably compact, without clockwork or complicated movements such as are common in other telegraphs. Though used double, with two sets of magnets, with a wire from each connecting with two needles upon the dial at the opposite station, the whole apparatus, including the tablet or dial, occupies but a few inches of space, and is always ready for instant use, however long it may have remained inactive. The magnets, of horse-shoe form, about 12 in number for each set, are 15 in. long and 1½ in. broad. They are laid one upon another in two piles near together, and fastened down to the table by screws. Opposite the ends of each pile, placed upon a rotating axis, is the soft iron armature, consisting of two cylinders wound around with long coils of fine copper wire covered with cotton. The wire of the two coils is connected together, and one end of each passes in a spiral through the axle to the platform upon which the apparatus rests. One end is thence carried into the earth, and the other goes to the electro-magnet of its own dial, thence to the distant station, and through the instrument there into the earth. The same arrangement is repeated with the other set. The axis of each armature extends toward the operator, and is provided with a crank handle by which each is turned to generate the electric current. The effect is seen in the movement of the two needles placed upon the dial over the magnets. It is asserted that this telegraph is worked with the greatest economy, that it cannot be disturbed by electric storms in the atmosphere, and that its average celerity has been found to be 27½ words a minute, with a maximum of 37⅙. In the United States the dial telegraph is largely used where operators are supposed to have but moderate skill, as in police and private telegraphy. The instruments are worked with a small battery. Primary signals are given by bells, and the letters are pointed out by the revolving needle. The transmitting part is the usual circuit wheel, which breaks and closes the circuit and produces the rotating movement of the needle of the distant instrument. This circuit wheel is arrested, in the process of telegraphing, by a series of pins, one of which is placed opposite each letter. When the A pin of the transmitter is pressed down, the circuit wheel is arrested just as it has caused the needle of the other instrument to rotate to A.—*Construction of Telegraph Lines.* Telegraph wires are usually carried over the surface of the country upon poles standing from 25 to 30 ft. above the ground, and placed from 80 to 100 yards apart. As poles are objectionable in cities, many plans have been devised for carrying the wires under ground. In London they are covered with gutta percha and tape and put into lead or iron pipes, which are laid under the sidewalk, or into creosoted wooden troughs filled with bitumen, which are buried in trenches beside the roadway. In Paris the wires are carried in lead pipes through the sewers and catacombs. The "American Compound Wire Company" have introduced a wire, consisting of a core of steel and envelope of copper, with a tinned surface, which, with equal conductivity and greater strength, weighs less and requires fewer supports. Another insulated wire, called "kerite wire," the invention of Mr. A. G. Day of New York, has a covering compounded of rubber and hydrocarbons. It is said to offer great resistance to oxidation, and that it may be exposed in the air or buried in the earth for years without serious injury. As, with batteries of the same intensity, the conductivity increases with the cross section of the wire, large wires are to be preferred to small ones upon long circuits. In working direct, a distance of over 400 or 500 m., the line is usually divided at some intermediate point into two distinct circuits, which are connected by means of a "repeater." If the circuit be broken on either side of the repeater, it will break the circuit on the other side also. The combined circuits can thus be operated from either end as if they were one continuous wire, while the current of each battery has to pass only half the distance between the terminal stations. A line can thus be extended indefinitely. Copper wire is a much better conductor than one of iron of the same size, and will carry the current from five to six times as far; but want of strength, and frequent breakage from its greater expansion and contraction by the changes of temperature, prevent its use except on important submarine lines. The insulation of the wires upon the posts is a matter of much importance, and is not easily effected, for any non-conductor interposed between the wire and the post becomes a conductor when its surface is wet with rain. Glass knobs with grooves around them for securing the wire have been made in a great variety of forms, and secured to the posts, or to the cross bars where there are several wires, by pins of wood or iron. A great improvement upon this is a glass cap exactly fitting over a wooden pin 1¼ in. in diameter, and having an outer covering of wood, saturated like the pin with coal tar and pitch, to which the wire is fastened, and which, projecting below and entirely covering the glass, keeps it dry and makes the insulation complete. Batchelder's vulcanite insulators have been very extensively applied in the United States. In Europe, insulators of earthenware and porcelain are used. In forests the wires should be allowed to pass loosely through the supports, so that in case of a tree falling upon them they need not be broken; but in an open country they are usually fastened to each post. On some telegraph lines in Europe and in Asia, the wires, instead of being supported upon poles, are buried beneath the ground. Their first cost is always heavy,

and many of them have soon proved failures through imperfection in the insulation. The wires are best insulated by coating them with gutta percha, and they are protected from injury by laying them in pipes of lead or of earthenware, or in wooden boxes preserved by saturating the wood with a solution of sulphate of copper or chloride of zinc. Some of these lines have worked perfectly for many years, but when they fail it is a matter of great expense and difficulty to discover their defective points.—In the extent of its telegraphic lines the United States has exceeded every other country. In 1860 it was estimated that there were over 50,000 m. in operation, and at present there is not less than 150,000 m. of wire. In the aggregate, 700,000 m. of wire spread their network over the earth for telegraphic purposes, including lines in Australia, India, China, and Siberia. Russia is engaged in extending an important line from Moscow to the Pacific so as to connect eastern Asia with Europe, and possibly hereafter with America by the way of Behring strait. This line was completed to Perm, on the borders of Siberia, and from that place across the Ural mountains to Omsk on the Irtish, in 1861. Thence it is continued to Tomsk, and S. E. to Irkutsk; next it passes the Altai mountains to Kiakhta on the Chinese frontier, thence to Cheta on the Amoor, and thence to Nertchinsk. From Orum, or some other point on the Amoor, one branch will go down the river and another southward to a Russian port on the Japan sea. The project of extending these lines to Behring's strait, and across to Alaska, Oregon, and California, which had been partially carried into effect on the American side, was abandoned after the Atlantic cables had been brought into working condition.—*Submarine Telegraphs.* The idea of a submarine telegraph appears to have been conceived by several of the earlier electricians. Salvá is said to have proposed one as early as 1797 between Barcelona and Palma in the island of Majorca. Experiments were made in India by Dr. O'Shaughnessy in 1839 with this object, and he insulated his wires by covering them with tarred yarn, enclosing them in split rattan, and covering this again with tarred yarn. Wheatstone in 1840 gave it as his opinion before a committee of the house of commons that a submarine communication between England and France was practicable. Morse, on Oct. 18, 1842, laid a copper wire, insulated by means of a hempen strand coated with tar, pitch, and India rubber, from Governor's island to the Battery in New York, and the next morning was beginning to receive communications through it, when the wire was caught in the anchor of a vessel getting under way, and being hauled on board was stolen by the sailors. Samuel Colt laid a submarine cable in 1843 from Coney island and Fire island, at the mouth of New York harbor, up to the city, and operated it successfully. The first submarine telegraph wire laid in Europe was across the Rhine from Deutz to Cologne, about half a mile; it was insulated with gutta percha, and laid by Lieut. Siemens of the royal Prussian artillery. This appears to have been the first application of gutta percha to this purpose, the substance about that time first beginning to attract attention. In 1850 a copper wire covered with gutta percha was laid between Dover and Calais by Brett, but its success was short-lived. The next year it was replaced by a cable of four wires, which has given complete satisfaction. In 1853 six cables (the longest of which, between England and Scotland, was about 100 m.) were successfully laid. In 1854 five other cables went into operation, the longest being only about 64 m. In 1855–'6 two more were added, that from Varna to Constantinople being about 160 m. Besides these, two cables had been laid in deeper waters: one from Newfoundland to Cape Breton, and another from Spezia to Corsica. The grand attempts to connect the European and American continents by a cable across the Atlantic, commenced in 1857 and perfected Aug. 5, 1858, have been noticed in the article FIELD, CYRUS WEST. Before these were undertaken great encouragement was given to the enterprise by the successful experiments made on Oct. 9, 1856, in transmitting distinct signals at the rate of 210, 241, and even 270 a minute through a number of connected coils of wires, insulated with gutta percha, and making a total length of about 2,000 m., increased to a virtual circuit of 2,300 m. by the interposition of fine wires at the joinings of the coils. The wires were excited by the magneto-electric coils of Whitehouse, and the signals were received upon the ordinary recording apparatus of Morse. But a great difference was afterward experienced in the working of the wires when submerged. Before the cable was laid it was ascertained that insulated wires acquire a new character when submerged, and that instead of transmitting the current as simple conductors, they are of the nature of the Leyden jar, the gutta percha corresponding to the glass, the inner wire to the interior coating, and the iron covering or the water itself to the exterior coating; and that consequently the cable must be charged throughout the entire length before any current is produced. Among other interesting phenomena, it was observed that the voltaic current is not transmitted so rapidly through such a conductor as the magneto-electric current; and that alternating positive and negative signals are transmitted more rapidly than successive signals of the same character. After being laid, the wires were first worked by the Ruhmkorff induction coils and a Smee battery, and afterward by a Daniell battery; but the current was for the most part so weak as scarcely to operate the most delicate relay, though susceptible to a current that can hardly be perceived on the tongue. The effect was indicated

at the Newfoundland station by the deflection of a delicate galvanometer, and at Valentia in Ireland by that of the reflecting galvanometer of Thomson, in which a delicate magnet carries a small mirror from which a beam of light is reflected. This ray being thrown upon a surface at some distance, a movement of the magnet that is not directly perceptible may be even measured upon a graduated scale. The transmitted current was, much of the time that the cable continued in action, so weak that every expedient of this kind was necessary to render the signals perceptible. From the first there was a defect in the part of the cable laid toward the Irish shore, which caused a temporary interruption of communications between the ships. Between Aug. 13 and Sept. 1 there were 129 messages of 1,474 words sent from Valentia to Newfoundland, and 271 of 2,885 words in the other direction. The message from Queen Victoria to the president of the United States, 99 words, occupied in its transmission 67 minutes. The rate of reception was very variable, the signals being often unintelligible and requiring several repetitions. Electricians were sent to Valentia, and the most powerful batteries, as well as the great magneto-electric machine of W. T. Henley, were applied to test the condition of the cable. The power thus employed was more than 1,000 times what would be required in an ordinarily well insulated conductor to give perfect signals to the mirror galvanometer. To the end of the cable a voltaic battery was connected by one of its poles, a galvanometer was placed in the circuit, the other pole was connected with the earth, and by these means the location of the defect in the cable was ascertained; but all attempts to recover it were unsuccessful. The cost of the cable was as follows: for 2,500 m. at $485 per mile, $1,212,500; for 10 m. at $1,250 per mile, $12,500; and for 25 m. shore ends at the same price, $31,250; making altogether $1,256,250. The expenditures of the company up to Dec. 1, 1858, had amounted to $1,834,500.—After the failure of this great enterprise attention was directed to the practicability of extending a cable across the Atlantic from Labrador to Scotland, by way of Greenland, Iceland, and the Faroe islands. The route is about 1,800 m. long, and presents no continuous length of submarine cable for a greater distance than that between Labrador and Greenland, which is about 600 m. Mr. T. P. Shaffner, of the United States, had obtained in 1854 from the king of Denmark a concession of exclusive rights in Greenland, Iceland, and the Faroe islands for this purpose. He sailed from Boston, Aug. 29, 1859, and made the preliminary surveys at his own expense, and he induced the British government to send a steam vessel to take the deep-sea soundings; but the project was not consummated. The failure of other deep-sea cables, as that between Sardinia, Malta, and Corfu, and the long cable from the Red sea to India, increased the distrust occasioned by the failure of the Atlantic cable of 1858. The result was that a committee, consisting of the most eminent electrical engineers, was appointed by the English chamber of commerce and the "Transatlantic Telegraph Company," to whom the duty was assigned of inquiring into the causes of these disastrous failures, and providing instructions for the future in regard to the manufacture, tests, and placing of cables. It appeared that the mechanical department of the subject was in a more advanced state than the electrical. The committee, after 18 months of hard work, published an elaborate report in 1863. Moreover, the theoretical researches of Thomson, Jenkins, and others, had thrown much light on the electrical requirements of submarine lines. Meanwhile, a cable was laid successfully between Malta and Alexandria in 1861, and the Persian gulf cable (about 1,330 m. long) in 1864. When Mr. Field visited England in 1862, to urge on a second attempt to establish telegraphic communications across the Atlantic, he found that the manufacturers, Messrs. Glass, Elliott, and co., were confident of their ability to make and place a good and durable cable between Great Britain and America, and were willing to incur a part of the risk. The second Atlantic cable, made by the "Telegraph Construction and Maintenance Company," was tested with every precaution, and found to be unexceptionable in its electrical conditions, and was shipped on board the Great Eastern in 1865. This cable (2,186 m. long) consists of seven copper wires (No. 18) twisted into a spiral, covered with four coats of gutta percha, between which are thin layers of Chatterton's compound. The external protection is made of ten iron wires, each surrounded by manila yarn. After about half of the cable had been paid out it broke, and the expedition was abandoned for the season. The total expenditure of money had been about $3,000,000. In 1866 a third cable, of similar construction to the second, but stronger, lighter, and more flexible, was placed on board the Great Eastern and successfully laid. The length between Trinity bay and Valentia is 2,134 m. Its first duty was to transmit a message of peace, viz., that a treaty had been signed by Prussia and Austria. Capt. Anderson returned with the Great Eastern to the place where the cable of 1865 had parted, and succeeded in splicing it and completing the line. In 1869 the French Atlantic line went into operation between Brest and St. Pierre, and between St. Pierre and Duxbury, Mass., the total length being 3,857 m. In 1870 more than 15,000 m. of cable were laid, including the Indian cables (from Suez to Aden, from Aden to Bombay, and from Penang to Singapore), the China cable, and the North China from Hong Kong to Shanghai and from Shanghai to Posiet in the Littoral province of Siberia. In 1874 the work was begun by the "Direct Cable Company" of laying the new Atlantic line between Ballinskilligs bay,

in Ireland, and Rye, New Hampshire, by the way of Nova Scotia. In spite of many obstacles and delays, the cable was put in position between Rye Beach and Torbay, N. S., and between Torbay and Newfoundland, also between Cahirciveen island and a point 200 m. E. of Newfoundland, before rough weather put an end to the work. The final splice of 200 m. was made early in the summer of 1875. In 1873 a cable was laid between Lisbon and Madeira; in 1874 Madeira was connected by cable with St. Vincent, one of the Cape Verd islands (1,200 m.), and St. Vincent with Pernambuco (1,845 m). In 1875 cables were laid between Jamaica and Porto Rico, Constantinople and Odessa, Zante and Otranto, and Barcelona and Marseilles. In all, more than 200 cables have been laid, with a length of about 50,000 m.—The interval of time which must elapse between the sending of successive signals through similar cables increases as the square of their lengths; and in different cables of equal length, this time is the least when the thickness of the insulating coating is one third of the diameter of the compound conductor. With the improved transmitting apparatus of Thomson and Varley, eight words can be sent in the time otherwise required for one. Seventeen words a minute have been sent through the French Atlantic cable. Thomson's syphon recorder quadrupled the speed of cable telegraphy. The current from the cable passes into a coil of wire suspended between the poles of magnets. The coil turns round in a direction depending upon the direction of the current. The motion of the coil is communicated by means of a thread and lever to a glass syphon which feeds itself with ink from a basin. The ink is electrified and spurts out against a moving strip of paper, and draws an undulating curve which indicates the letters of the message. The speed of working with this recorder is about the same as with the reflecting galvanometer; and in either case it is much greater than could be attained by the moving armature, which requires that the current should rise and fall by large differences; and this would take more time.—*Telegraphic Disturbance.* The offices and operators of air lines of telegraph are exposed to accidents from lightning, either from the direct stroke or the induced electricity when a discharge occurs between two clouds. A great many lightning guards have been devised. Sabine mentions eleven. In lines which follow the undulations of mountainous regions (as between Vienna and Milan), there is so great disturbance from atmospheric currents, even under a blue sky, that it is impossible to send messages at certain hours. The aurora sometimes acts powerfully upon the wires, interfering with the battery currents. On such occasions, if the battery be taken off, the messages may be sent by means of the current induced by the aurora. The action of cable lines is disturbed by earth currents. Generally, the difference of electric potential between different parts of the earth is small; but it is subject to sudden and capricious changes, and amounts sometimes to that of a battery of 140 of the Daniell elements. The direction of these earth currents is such as to derange particularly the Atlantic lines. The instruments are protected by the use of the condensers of Varley and others. These earth currents must not be confounded with those excited when plates of zinc and copper are buried in the earth, which Kemp, Fox, and Reich made the subject of numerous experiments, and which Bain, Palagi, and others put into the harness to work the telegraph.—*Various Uses of the Telegraph.* The electric telegraph has been applied to uses never contemplated by its originators. In 1852 Channing and Farmer of Boston devised a system of telegraphic fire alarms, which was adopted in the city of Boston. Five so-called signal circuits were extended from the city hall to different parts of the city, and in connection with these were stationed 50 signal boxes attached to buildings at convenient points. The door of a box being opened, a crank is seen with directions for the number of times it is to be turned to convey to the central office the number of the station and district. From the central station five wires called alarm circuits connect with the different fire bells throughout the city, the hammers of which, run by weights, are set in action by the telegraph itself and strike the number of the district and station of the alarm. The electric current is excited by a magneto-electric machine which is set in motion by the pressure of the water with which the city is supplied, and the same power is employed to wind up the weights that move the bell hammers. The bells have been rung, as an experiment, from Portland through the telegraph wires extending to that place. The fire alarm also affords an incidental protection to the city from lightning. Large metallic surfaces being placed near the wires at all the stations and connected with the ground, a stroke of lightning upon the wires will leap across to these conductors, and pass harmlessly to the ground, while the artificial current possesses too little intensity ever to overcome the intervening space, and continues in the circuit. Similar arrangements are provided upon many telegraph lines. The telegraphic fire alarm has now been introduced into all the larger cities. The fire alarm telegraph of Boston is employed to designate the exact noon by a single stroke upon the bell of the Old South church, an exact chronometer being placed in the circuit and arranged so as to pass the current at 12 o'clock precisely. By a similar arrangement in London a large ball is made to drop exactly at 12 o'clock from a pole erected in the Strand by the action of a current from the royal observatory. The same thing is also done at Nelson's monument, Edinburgh. In Paris a cannon is fired upon a similar plan. Chro-

nometers in observatories are also made to run synchronously with a standard instrument by means of the electric current. Recently, the Harvard college observatory has established a telegraphic connection with Boston, and thence with the lines which diverge from that city, so that a uniform time can be distributed to all the railroad stations in New England. In a similar way Greenwich time is given to the whole of Great Britain. The application of the telegraph to the determination of longitudes has been described in the article Coast Survey, vol. iv., p. 759. Upon some railroads the telegraph is used with great advantage for regulating the running of trains. In numerous places telegraphs have been constructed for private purposes, and in London from the house of commons to the committee rooms. The transactions of the stock exchange in New York are telegraphed to the brokers' offices and the hotels, and are instantly and simultaneously made known in a thousand different places, where they are sometimes recorded by automatic printing instruments. For this purpose a very rapid printer has been devised. The usual type and escape wheels are made very light, and are rotated, not by electricity, but by a spring. The current is reversed at every vibration, and the printing is effected by the power of a magnet, which is included in the same circuit with those that liberate the escape wheel; but it is made more sluggish in action so that it does not perform its work until the arrest of the circuit wheel at a letter gives time for it to be charged. This instrument, which occupies only one sixth of a cubic foot of space, will print 800 letters a minute.—A system of telegraphs for the use of large cities was devised by Wheatstone, by which a company leases the use of a small wire by the year to individuals. For distances not exceeding 20 m. a copper wire no larger than a cotton thread is sufficient. Numbers of these, insulated by being wound with thread, may be brought together into one cord, and suspended from strong iron wires passed in different directions upon the houses. The latter, communicating with the ground at numerous points, will convey away all atmospheric discharges that might otherwise be troublesome. The "Law Telegraph Company" in the city of New York has established a complete system of communication by means of dial instruments between the leading law firms and the courts. A rapid system of signalling is used, by which any member of the company can be put, through the agency of a central office, into direct private communication with any other member, or with the courts of New York or Brooklyn. The Chester dial is employed by this company. In the automatic fire alarm, a circuit is closed by the expansion of metal under a rising temperature. The circuit closer, which is called a thermostat, is attached to the ceilings of stores or dwellings, and is adjusted to work at a fixed temperature. In the city of New York houses and stores furnished with these instruments are connected telegraphically with the fire patrol, the usual apparatus for indicating the locality of the fire being included in the system. The district telegraph system, which has been introduced in New York, Boston, and elsewhere, by which a messenger, policeman, or fireman can be summoned to any house that adopts it, is a still wider extension of Wheatstone's scheme. On a smaller scale, telegraphic communications may be kept up between the remote quarters of a ship or yacht; the electro-magnetic bell-ringer may be used for domestic purposes, and the burglar alarm for the protection of private dwellings. By means of Batchelder's electro-magnetic tell-tale clock, the times are recorded when a watchman visits the different points of his beat. The most difficult piece of music may be punched out upon a moving strip of paper, and then played automatically by means of electro-magnetism. On the field of battle, telegraphic lines may be quickly extemporized, and an interchange of reports and orders may be maintained between the outposts of an army and headquarters. During the American civil war, telegraphic field trains were in use. A machine has been invented, operated by keys, which enables a reporter to secure a printed copy of the very words which come from the mouth of the orator. In some countries, as in England, where the lines have been purchased by the government, the telegraphs are associated with the postal service. For short distances the pneumatic telegraph is used, the written messages being driven through underground pipes by condensed air. For this purpose three engines of 50 horse power each are in constant service at the central post office in London.—*Multiple Telegraphy.* During the last quarter of a century various attempts have been made to contrive ways by which two messages should be sent at the same time, in the same or in opposite directions, over a single wire. Gintl, Edlung, Wartmann, Frischen, Siemens, Halske, Duncker, Starke, Rouvier, Zantedeschi, Farmer, and Stearns have all experimented with this object, and some of them have invented ingenious instruments. In 1849 Siemens and Halske took out a patent in England for a method of transmitting simultaneously a plurality of messages. In 1855 Starke devised a method of sending two messages at the same time upon the same wire. By means of two keys, and two batteries of different intensities, two independent receiving magnets were worked at the other end of the line, either separately or together. In 1854 Siemens and Halske independently invented the differential method of sending two messages at the same time in opposite directions. About the same time Farmer devised a way of doing the same thing, using two auxiliary batteries in combination with two principal batteries. The essential conditions for successful duplex tele-

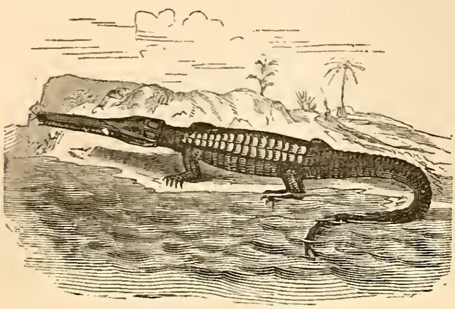
graphy are: 1, that neither key should put in action the receiving magnet at its own end of the line; 2, that in all positions of the key signals should be sent through a line of constant length and capacity. This is done by dividing the current from the battery at each end of the line equally between the line itself and an equivalent resistance coil and condenser, and winding the wire round the receiving magnets in such a way that the two parts of the current produce equal and opposite magnetism in the core of soft iron. The modifications made by Stearns in the arrangement of Siemens and Gintl have obviated all the practical difficulties, and made duplex and even quadruplex telegraphy a success in the United States. By means of Stearns's invention, known as the Franklin, the duplex system has gone into effect, not only between Boston and Washington, but also between Cape Breton and San Francisco, and has been introduced into England. The quadruplex system works well between Boston and New York. The phonetic system of Gray and Bell (which is still in its infancy) aims to increase indefinitely the number of messages which can be sent simultaneously over a single wire, by using tuning forks, moved by electro-magnets, for sending and receiving the signals. Only one fork at the receiving station is in unison with a particular fork at the sending station, and responds to it. Experiments upon a similar system were made by Paul la Cour in Copenhagen on a line of 242 m. in 1874, an account of which was presented to the royal Danish academy of sciences. It was thought that by this arrangement not only many messages could be sent at the same time on a single wire, but also a message could be received only by the station for which it was intended. —See Schellen, *Der elektromagnetische Telegraph* (Brunswick, 1850); Moigno, *Traité de la télégraphie électrique* (Paris, 1849); Highton, "The Electric Telegraph, its History and Progress," a number of Weale's series (London, 1852); Jones, "Historical Sketch of the Electric Telegraph" (New York, 1852); Turnbull, "The Electro-Magnetic Telegraph" (Philadelphia, 1853); Schaffner, "Telegraph Companion" (2 vols., New York, 1854-'5), and "The Telegraph Manual" (1859); Prescott, "History, Theory, and Practice of the Electric Telegraph" (Boston, 1859); Dumoncel, *Télégraphie électrique* (Paris, 1864); Field, "History of the Atlantic Telegraph" (New York, 1866); Griscom, "The Telegraph Cable" (Philadelphia, 1867); Sabine, "The Electric Telegraph" (London, 1867); Cully, "Handbook of Practical Telegraphy" (New York, 1870); Goldsmid, "Telegraph and Travel, a Narrative of the Formation and Development of Telegraphic Communication between England and India" (London, 1874); and Douglas, "A Manual of Telegraph Construction" (1875).

**TELEKY, László**, count, a Hungarian statesman, born in Pesth, Feb. 11, 1811, died there, May 8, 1861. He studied at Pesth and Patak, wrote a drama, *Kegyencz* ("Favorite"), and became a leading opposition member of the diets of Transylvania and Hungary. In September, 1848, he went as envoy of the Hungarian government to Paris, where he published *Le bon droit de la Hongrie* (1849). After the close of the Hungarian war he resided mainly in Paris. During the war of 1859 he was a member of the Hungarian national committee in Italy, and in 1860 went to Dresden, where he was arrested and surrendered to the Austrian government. Francis Joseph restored him to liberty on the promise of severing his connection with the Hungarian refugees and abstaining from political agitation. After a few months, however, Teleky accepted an election by his former constituents to the house of representatives. The diet was opened April 6, 1861. The debate on the address to the monarch, prepared by Francis Deák, was to open on May 8, and Teleky, the leader of the radicals, who opposed any measure looking like a recognition of Francis Joseph as king of Hungary, prepared an elaborate discourse on the situation. This was found on his desk on the morning of the 8th, and near it on the floor the dead body of the writer, whom, as various indications showed, dissatisfaction with his own course had led to end his life by a pistol shot.

**TELEMACHUS**, a legendary Greek prince, son of Ulysses and Penelope. When Ulysses went to Troy, Telemachus was an infant. About the time for the father's return the son made an unsuccessful endeavor to eject the suitors for his mother's hand, and then set out to seek information of his father. Accompanied by Minerva, in the guise of Mentor, a faithful friend of Ulysses, he visited Pylos and Sparta, and was kindly received by Nestor and Menelaus. Returning home, he found his father with the swineherd Eumæus, disguised as a beggar, and aided him in slaying the suitors.

**TELEOSAURUS**, a genus of fossil crocodilians of the secondary epoch established by Geoffroy, differing from the living crocodiles in having biconcave vertebræ. The general form of the cranium was that of the gavials; the nostrils opened anteriorly at the end of the muzzle and posteriorly on a level with the jugal arch; the lower jaw was spoon-shaped at the end, with teeth on the sides like canines, the other teeth being small, equal, conical, and adapted for seizing a fish prey; the body was protected by larger and more solid plates, the anterior limbs were smaller, and the posterior more fin-like than in the present crocodilians. The strata which enclose their remains indicate a marine habitat. The genus has been divided by modern palæontologists into several subgenera, as given by Pictet. In the lias is found *mystriosaurus* (Kaup), having a very long muzzle, flattened head, and eyes directed upward. The *T.* (*M.*) *Chapmanni* (König), from the upper lias of Yorkshire, England, is described in the "Philosophical

Transactions" of 1758; the vertebræ were 64, 16 being dorsal, and the teeth about 70 in each jaw; some of the dermal plates were 3½



Teleosaurus Cadomensis.

in. in their transverse diameter; it attained a length of about 13 ft. The name has been generally restricted to the species found in the oölite, especially the *T. Cadomensis* (Ét. Geoffr.), or crocodile of Caen, from the limestone of Normandy. This is characterized by large orbits near together, a flattened muzzle five times as long as wide, very long transverse processes of the dorsal vertebræ, and thick rectangular scales forming 10 regular series, each containing 15 or 16; it must have attained a length of 20 ft.

**TELEPHONE** (Gr. τῆλε, afar, and φωνεῖν, to speak), an apparatus for transmitting sounds to a distance, through the agency of electricity. The principle of the magnetic telephone depends upon two things: 1, that a thin soft-iron plate, placed in a confined position, as in an artificial ear, will be thrown into vibrations by sound waves, just as the tympanum of the natural ear is affected by similar waves; and 2, that if these vibrations are produced near one end of a steel magnet around which an insulated wire is coiled, a magneto-electric current will run through the wire each time that the iron plate approaches and recedes from it. If this wire be carried to a distance and coiled around a second magnet, the electric current thus induced will simultaneously affect the magnetism in it; and if a thin iron plate, similar to the first, be placed near its end, in the same relative position as the one in front of the first magnet, the vibrations of the first plate will be reproduced in the second. To recapitulate: In the human ear sound waves induce vibrations in the tympanum, and these vibrations are conveyed to the auricular nerves through a series of small articulated bones. In the telephone similar waves cause vibrations in a soft-iron disk, called the diaphragm; these vibrations induce electric currents, which, passing through wires, cause tremors in a second magnet, and these reproduce in a second diaphragm the original vibrations, which carry to the tympanum of the listener the exact sounds which produced the vibrations. As the instruments at each end of the wire are precisely alike, the action is reciprocal, and sounds may be conveyed in either direction. The construction of the telephone will be best understood by a reference to the diagram, fig. 1. In this, *b b* represents the section of a thin tube, made with a flange which bends outward. Next to this flange is a thin iron plate, *c c*, which constitutes the diaphragm of the instrument, and which is thrown into vibrations by the sound waves. A wooden ring or washer, *d d*, is placed next to this, and upon it a spool-shaped tube, *e e*, just large enough in the barrel to admit the magnetized steel rod *g*. The parts may be screwed up tightly together, by means of the screws *h h*. The mouthpiece, *a a*, is shaped like a funnel, so that the voice may be concentrated on a small part of the diaphragm. Around the spool is wound about 50 yards of fine silk-covered copper wire, the ends of which are joined to the line wires, *f f*. These connect with another precisely similar instrument at a distance from the first. To operate the telephone, the magnet is pushed in until it nearly touches the diaphragm, *c c*. Any sound now made in the mouthpiece, *a a*, causes a vibration in the diaphragm, *c c*, which is communicated to the magnet, and through it to the wires. The latter convey the thrill to the magnet of the second instrument, which in turn causes vibrations in its diaphragm, and this reproduces the sound waves which caused the vibrations in the first instrument. Thus the sounds made in the mouthpiece of the first instrument are conveyed over miles of wire, and reproduced so accurately by the second instrument that the words of a speaker may be distinctly heard, and even the tones recognized. Conversation has been carried on through the telephone by persons 300 miles apart. Sounds have been conveyed much further; but beyond that distance the articulation is so indistinct that words are unrecognizable. In using the telephone, the instrument is held close to the lips, and the speaker talks loudly and distinctly into the mouthpiece. The words are repeated at the other end of the circuit with the same pitch

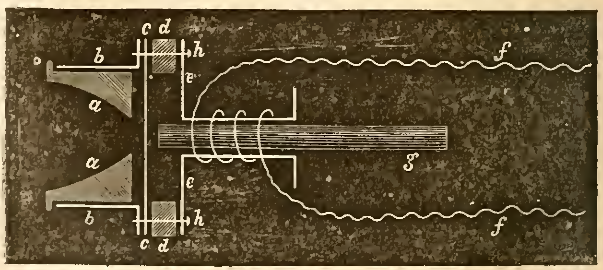


Fig. 1.

and cadence, even the character of the speaker's tones being so faithfully reproduced that voices are easily distinguished; but the tones are in a measure ventriloquial, and seem to come from a great distance. No previous training is required to enable any one to use the telephone. The instrument has merely to be held to the ear to enable the operator to hear distinctly any message sent from the other end. The same instrument is then placed to the mouth and the answer returned. To facilitate the transmission and reception of messages, two instruments are generally used by each operator, one of which may be held to the ear and the other used for speaking. If several telephones are connected with one wire, the sounds sent over the circuit are reproduced by each, so that any number of persons may listen to the same message; many sounds may also be transmitted at the same time, like the singing of the different parts of a song, in which case each performer sings into a separate instrument. The tones of a musical instrument, or of a collection of instruments, may be conveyed and reproduced in the same manner. A telephonic concert was given in Steinway hall, New York, April 2, 1877, in which all the music, instrumental and vocal, was executed by performers in Philadelphia, and transmitted over the ordinary telegraph wires.—The principle of the telephone has long been known; all that is new about it is its adaptation to practical uses. Electric telephones, devised not long after the introduction of the telegraph, were capable of conveying to a distance musical tones; but the other characteristics of sound, intensity and quality or *timbre*, were entirely wanting. In 1837 Prof. Charles G. Page, of Washington, discovered that the rapid magnetization and demagnetization of iron bars produced a molecular change of sufficient intensity to cause a sensible sound. De la Rive, of Geneva, increased these musical effects in 1843, by operating on long stretched wires. In 1854 Charles Bourseulle, under-inspector of the telegraphic lines at Auch, France, suggested the practicability of transmitting speech by electricity in almost precisely the way in which it has been accomplished by the telephone of to-day; but, although his plan was published in the Count du Moncel's *Exposé des applications de l'électricité*, it does not appear to have been tested practically. The first to utilize Page's discovery was Philip Reis, of Friedrichsdorf, Germany, who in 1861 constructed a telephone in which a vibrating diaphragm was caused to make and break a galvanic circuit. Reis's apparatus reproduced the tone or pitch of sounds, so that the successive notes of a melody could be distinctly recognized; but they were all of the same intensity, because the currents which formed them were all of the same strength. It was therefore only a philosophical toy, and of no practical value. In 1873 Elisha Gray, of Chicago, produced what he called his "resonator." By attaching organ pipes to this, the sounds were magnified, and he was able to fill a large hall with music played 100 to 200 miles away. Gray also proved the practicability of transmitting composite sounds, such as chords, to a distance. By his apparatus the intensity as well as the pitch of sounds was reproduced; but it was reserved for Alexander Graham Bell, of Boston, to discover a method by which all the characteristics of sound, pitch, intensity, and quality, could be transmitted. This rendered possible the reproduction at a distance of human speech with all its modulations. The telephone exhibited by him in Philadelphia in 1876 was worked with an electro-magnet, but he subsequently adopted a permanent magnet. An external and a sectional view of the Bell telephone are given in figs. 2 and 3. The instrument is about 6 in. long, $2\frac{1}{3}$ in. in diameter in its widest part, and 1 in. in diameter in the tube. The tube F, fig. 3, which is made of hard rubber, contains the magnet A, whose distance from the diaphragm, E E, is about $\frac{1}{32}$ of an inch. The magnet used in the latest form of the instrument is a square compound magnet, $4\frac{1}{2}$ in. long and $\frac{1}{2}$ in. in diameter, formed of three pieces riveted together. On the end next to the diaphragm is fitted a wooden spool, about $\frac{1}{2}$ in. long, wound with fine silk-covered copper wire to 60 ohms. A section of this is shown at B. The ends of the wire are continued through C C to the binding screws D D, where they connect with the line wires. The diaphragm is a circular piece of ordinary photographer's plate, used for ferrotypes, and is varnished on both sides, to prevent

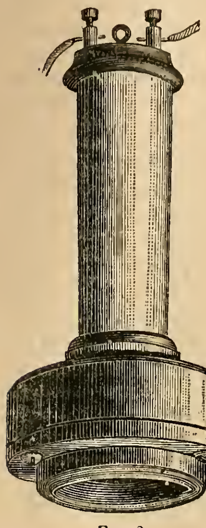

Fig. 2.

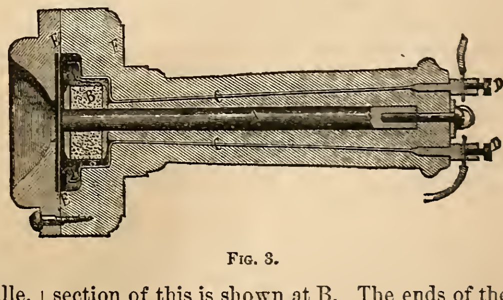

Fig. 3.

its rusting from the dampness caused by the breath. Mr. Bell has received two patents in the United States for the telephone, one bearing date March 7, 1876, and the other Jan. 30, 1877; and his instrument is now in practical use in many cities in this country and in Europe. Among others who have made extensive experiments in the transmission of sounds to a distance are Prof. A. E. Dolbear, of Tufts college, Massachusetts; G. M. Phelps, of New York; and Thomas A. Edison, of New Jersey, the inventor of the phonograph (see PHONOGRAPH). The Dolbear telephone is essentially the same as the present form of the Bell instrument, and was devised by its inventor in the autumn of 1876 without any knowledge of the mechanism used by Bell. Prof. Dolbear claims that he was the first to utilize magneto-electric currents for the transmission of speech. The Phelps instrument is also the same in principle, but differs in exterior form. In the Edison telephone the diaphragm is made to vibrate against a disk of carbon, which forms a part of an electric circuit, the current of which is generated by a two-cell battery. The resistance of this disk varies in accordance with the pressure on the diaphragm, and occasions a proportionate variation in the strength of the current, which is thus made to reproduce all the characteristics of vocal waves.

**TELESCOPE** (Gr. τῆλε, far, and σκοπεῖν, to view), an instrument for aiding the eye in viewing distant objects. The general construction of the telescope is based upon the property possessed by a convex lens or concave mirror of converging to a focus the rays of light falling upon it from any object, and of forming at that focus an image of the object itself. This image may be rendered visible, as in the camera obscura, by interposing at the focus a white screen, a plate of ground glass, or a cloud of light smoke within which the image will appear suspended. But if the rays be allowed to proceed without interruption, and the eye be placed in the axis of the lens or mirror and at the proper distance from the focus, the image will be seen more distinctly than before; and if the focus be nearer to the eye than to the lens, the apparent dimensions of the image will be greater than the apparent dimensions of the object itself. This is the simplest, though not the common form of the telescope. Usually a second lens,

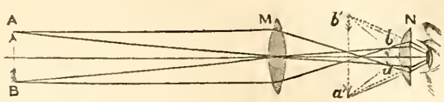

FIG. 1.—Astronomical Telescope.

of shorter focus than the first, is introduced near the image, the effect of which is to increase still further the apparent magnitude of the object; and thus is constituted the ordinary telescope, which in its elementary construction consists of an "object glass" or "object mirror," of as large dimensions as practicable, and an "eye lens," which enables the eye to receive the image under the greatest practicable angle. In fig. 1, M is the object glass and N the eye lens. The inverted image $b\ a$ of a distant object A B is formed between the eye lens and its principal focus, and the eye lens then gives a magnified image of it, $b'\ a'$. The object glass is always necessarily convex, and the mirror concave, but the eye glass may be either; if convex, it is placed at the proper distance beyond the focus, and, the rays having crossed, the image then appears inverted; if concave, as in the common opera glass, it is placed within the focus, and objects appear in their natural position. The magnifying power of the instrument is measured by dividing the focal distance of the object glass by that of the eye piece; the illuminating

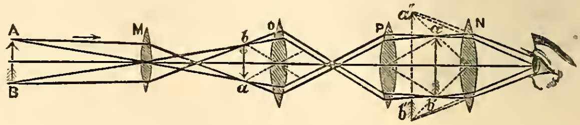

FIG. 2.—Terrestrial Telescope.

power depends mainly on the size of the object glass. In the terrestrial telescope, commonly called spy glass, the image is produced in its natural position. To effect this two additional lenses, O and P, fig. 2, called condensing glasses, are introduced between the real image and the eye lens. The object A B produces an inverted and smaller image at $b\ a$. The lens O being at the distance of its principal focal length from $b\ a$, the rays which fall on P will be parallel, and the image $a'\ b'$ in the principal focus of P will be erect, as will also be the magnified image $a''\ b''$.—It is believed by many authorities that the theory of both the telescope and the microscope was known to Roger Bacon, and the telescope is said to have been used by Digges before the 17th century; but the first really definite accounts of the invention date from the latter part of the year 1608. Magnifying lenses had long been known, and even the compound microscope had been invented by the Jansens nearly 20 years before this date; a discovery which has somewhat embarrassed the study of the question before us from confusion of the by no means explicit terms in which both instruments are described. But it is now generally conceded that the honor of making the first telescope belongs to one of two individuals, Hans Lippersheim, a spectacle maker in Middelburg, and Jacob Adriansz, called also Metius, a native of Alkmaar. Lippersheim, on Oct. 22, 1608, presented to his government three instruments with which "one could see things at a distance," applying at the same

time for a "protection" or other equivalent for a patent. Metius made a similar present and a similar application later in the same month, but said that he had manufactured such instruments two years before. It has been frequently said that Zacharias Jansen also invented the telescope more than a year later; but the evidence adduced only proves, according to Olbers, that he made telescopes which may have been imitated from those of Lippersheim; and this is the more likely as both were spectacle makers in the same city, and it is hardly possible that the public transaction with the latter could have escaped the knowledge of Jansen. The attempt was made by the states general, it is said, to retain to themselves the knowledge of this invention, the importance of which in war was at once perceived by Prince Maurice; but it is also believed that the French ambassador soon obtained from them an order for two telescopes for his own government. It is certain that the report of the invention soon spread abroad, and the instruments found their way to London, Paris, and Venice. But by no one was the idea more eagerly welcomed, or its great importance more quickly recognized, than by Galileo, then visiting Venice. He was evidently willing, at a later day, to be thought the second inventor, guided only by an uncertain rumor; but it is said that he actually saw one of the Dutch telescopes. Returning to Padua with some lenses, he immediately began to improve upon what he had seen, if not to experiment independently under guidance of the mere report, and he soon found a better and more certain result than had been chanced upon by the original inventor. He made a leaden tube, and fitted at one extremity a double convex lens for object glass, and at the other a double concave for eye piece. This, his first telescope, magnified only three times; he then made another of more than double this power, and soon after, with a magnifying power of 30, he began to study the heavens, where his first discoveries excited more wonder than that of the "optic glass" itself. The popular curiosity was so great, as he himself tells us, that he was compelled night after night to stand by his glass to show its wonderful performances. The phases of Venus, questioned hitherto, were revealed to sight; the satellites of Jupiter and the oblong shape of Saturn were distinctly seen; the lunar mountains were measured; spots were found upon the sun's disk; and the milky way was resolved into stars. The Galilean telescope produces an erect image. The object glass A B would form an inverted image at $b\ a$, fig. 3, but the concave eye lens N refracts the rays, which being produced backward forms an upright image at $a'\ b'$. In 1609, the same year in which Galileo's telescopes were made, others found their way into England, and were soon sought after with an avidity that was stimulated by the report of Harriot's discoveries. This young astronomer made drawings of the moon, discovered the satellites of Jupiter, and observed the spots upon the sun. The new "cylinders," as they were called, were soon in general use, and were exposed for sale in Paris in the early part of the same year. These first telescopes are supposed to have been all made with a concave eye lens. Kepler in 1611 suggested the use of a convex eye lens; but the first actual application of one was made by the capuchin Schyrle de Rheita, who describes it in his work *Oculus Enoch et Eliæ* (1645). This eye lens gives a much larger field of view, but shows objects inverted. On the other hand, the Galilean telescope had the advantage of greater distinctness and brightness than was found in the "astronomical" form. The true cause of this advantage is now known to lie in the partial compensation by the negative eye piece of the aberrations caused by the object glass, the result being in this case the difference, while in the astronomical telescope it is the sum, of the aberrations of the two lenses. Rheita invented also the binocular or double telescope, a construction which frequently recurs afterward, but always as a thing of curiosity rather than of practical utility until in modern days, as the double opera glass or lorgnette, it has become serviceable in reconnoissances, terrestrial and celestial.—The very first attempts to gain magnifying power and light by enlarging the object glasses of telescopes, revealed a most unexpected and formidable obstacle. It was found that all objects appeared strongly tinged with prismatic colors. This obstacle remained unexplained until the time of Newton, and unconquered more than half a century longer. But if at the time insurmountable, it did not prove unavoidable, for it was ascertained that by making the focal distance of the object glass very great in proportion to the diameter, the colored fringes could be rendered practically imperceptible. Enormously long telescopes were therefore constructed, and it was with them that the brilliant discoveries of that time were made. Huygens used telescopes of his own manufacture, and one of his object glasses, 123 ft. in focal length, is still to be seen in the library of the royal society of London. English makers also produced telescopes of nearly equal dimensions, and Auzout in Paris spoke of surpassing all others, but it does not appear whether he succeeded. The elder Campani, at Rome, made lenses of from 70 to 136 ft. focus, and with these Cassini discovered two of the satellites of Saturn. Cassini also used

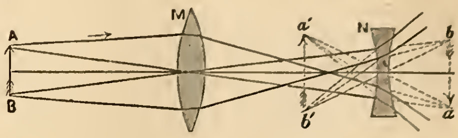

FIG. 3.—Galileo's Telescope.

other lenses made by Borelli of 40 and 70 ft., and by Hartsoeker of not less than 250 ft. focus. These object glasses were used without any tube, the lens being placed upon a mast, or, as Cassini recommended, at the angle of a tower, and controlled, not without considerable difficulty, by cords leading to the observer at the eye lens.—The source of the inconveniences attending the use of shorter lenses was generally supposed to lie wholly where it did really lie in part, in the imperfect collection of the rays of light, which were at that time believed to be homogeneous, into a simple focus. It was distinctly understood that the rays which passed through a lens near its centre would not be refracted to precisely the same point with those which pass through it near its circumference; that is, there would be what is technically called spherical aberration. This is a true cause, but by no means the whole cause of the indistinctness of images in the telescope. Accordingly, with that belief, it was thought the evil might be remedied by grinding lenses with other surfaces than spherical, and machines were devised by Descartes, by Hevelius of Dantzic, by Du Son of London (who ground deep parabolic concave lenses, with which he asserted that telescopes might be used "with full aperture," and yet show no colors), by Sir Christopher Wren, and others. But the main reliance of the astronomer until near the close of the century was in the aërial telescope, with which, unwieldy as it was, many brilliant discoveries were made.—An improvement, of more importance than that of the figuring of lenses, consisted in the modification of the eye piece. By the introduction of more than one convex lens, Rheita had reinverted the image; but this was all the gain that either he or Kepler, who also proposed the same thing, seems to have expected. In fact, there was an increase of aberrations which caused distaste for the plan, and it was not until about 1659, when Huygens invented the combination which still bears his name, that much advantage was gained by multiplying lenses. This eye piece is composed of two convex lenses whose focal lengths are as 3 to 1, which are separated from each other by an interval equal to half the sum of these focal lengths, the place of the telescopic image being between the lenses. This arrangement was found to have a remarkable advantage in point of distinctness over the single eye glass, by reason of the apportionment of spherical aberrations between the lenses, and the consequent less amount of injurious effect in the result, while no addition whatever was made to the color of the images formed by the object glass. To this day the "Huygenian eye piece" remains one of the best combinations for ordinary viewing purposes. Another eye piece, less successful, was constructed by Campani with three lenses so arranged as to show objects "without any iris or rainbow colors."—The refracting telescope remained full three quarters of a century without further material improvement. Morin, professor of mathematics in the collége de France, first in 1634 attached a telescope to the moving index of a graduated arc, in order, as he says, "to measure the fixed stars quickly and accurately." He was also the first to gain sight of stars in the daytime. But it was only after the introduction of fixed threads into the field of the telescope that it became a really useful auxiliary to instruments of measurement. At the present day it seems at first strange that astronomers should have preferred the simple "sights" or "pinnules," with which they had always been accustomed to observe, to the far more accurate perception furnished us by the telescope; and yet they, without any means of designating the centre of the field of view, and with only the feeble optical power at their command, were right in their preference. Even as late as 1673, Hevelius argued earnestly in favor of the pinnules for observing, from a want of confidence in the new method. As early as 1641 Gascoigne, an accomplished young English astronomer, had applied fixed threads to the telescope, and had also invented the wire or filar micrometer. He perished at the battle of Marston Moor, and his invention, of which no account had been published, remained forgotten until nearly 30 years after, when an opportunity for reclamation occurred upon the reinvention of the micrometer by Auzout. About the same period Roemer gave to the telescope one of its most important applications, by attaching to it an axis at right angles to its length, and placing it so as to revolve in the plane of the meridian; and shortly afterward Picard in Paris and Flamsteed at Greenwich, following up this idea, commenced a new era in observation. (See Transit Circle.)—Mersenne, in his correspondence with Descartes, had before 1639 suggested the practicability of using a concave mirror instead of the principal lens in the telescope. In 1663 James Gregory of Edinburgh published, in his *Optica Promota*, the plan of a reflecting telescope, consisting of a concave mirror, perforated in the centre, by which the rays were to be converged to a focus before it, and after crossing would be received upon a second small concave mirror, be reflected back by the latter, and, crossing again near the opening in the first reflector, would be there received by a lens and transmitted to the eye. The rays having crossed twice, objects would appear in their natural position. An unsatisfactory attempt was made to construct such a telescope. Newton now took up the study. He soon found the true cause of the prismatic colors, and concluded "that the perfection of telescopes was hitherto limited, not so much for want of glasses truly figured according to the prescriptions of optic authors, . . . as because that light itself is a heterogeneous mixture of differently refrangible rays. So that, were a glass so exactly

figured as to collect any one sort of rays into one point, it could not collect those also into the same point which, having the same incidence upon the same medium, are apt to suffer a different refraction." Thus he was led "to take reflectors into consideration," since here there would be no separation of colors; but inasmuch as any irregularity of figure in a concave mirror would produce greater distortion in the image than would be the case with a lens, "a much greater curiosity [nicety] would be requisite than in figuring glasses for refraction." The Gregorian construction, mentioned above, appeared to him to have such disadvantages, that he "saw it necessary to alter the design, and place the eye glass at the side of the tube." Having then found an alloy of copper and tin which appeared to possess the requisite qualities for mirrors, and having also devised a "tender way of polishing proper for metal," he attempted the construction of a reflecting telescope upon the plan which has ever since borne the name of Newtonian, and soon produced an instrument with which he could discern the "concomitants" of Jupiter and the phases of Venus. Another one made soon after (1671),

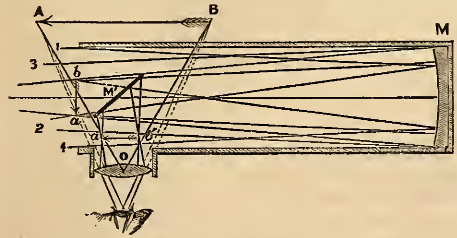

FIG. 4.—Newton's Telescope.

having a speculum of $1\frac{1}{8}$ in. diameter and $6\frac{1}{3}$ in. focus, was presented by him to the royal society of London, by whom it is still preserved. In these telescopes the mirror M, fig. 4, is at the lower end of the tube, the mouth of which is directed toward the object to be observed. The rays 1 and 2 from one end of the object being reflected toward *a*, and the rays 3 and 4 from the other end toward *b*, an inverted image of the object would be formed at *b a*; but a small plane mirror M′, interposed at an angle of 45°, diverts the image to *a′ b′*, and the eye lens O magnifies this into A B. In the same year that Newton's new telescopes were made, Cassegrain, a Frenchman, proposed still another construction. The large mirror was perforated, but the rays proceeding from it were, before reaching their focus, received upon a small convex mirror which sent them back with less convergence to form the image near the eye piece. It was asserted that this form, which like Gregory's was not immediately brought into use, would possess several advantages over the Newtonian; but the English philosopher showed that these advantages were rather objections, and that the difficulty of properly working the mirrors would always be a serious obstacle to their general acceptance. In fact, we hear little more of them until 70 or 80 years later, when Short, a celebrated artist of Edinburgh, revived their manufacture, and, by his peculiar skill in figuring and mutually adapting the mirrors ("marrying them," as he termed it), brought them into favor for a time. But practical difficulties, especially in the manipulations of the large speculum, interposed for many years to prevent even the Newtonian construction from coming into general use. It was known indeed that in order to reflect all the rays accurately to the same focus, the figure of the mirror should be not spherical but parabolic; but no method was known whereby this figure could be attained with certainty. At length, in 1718, Hadley made a mirror 6 in. in diameter and with a focal length of 62 in., which bore a magnifying power of 230. This instrument may be considered to have established the reputation of reflectors; for on being compared by Bradley and Pound with the 123-foot aërial telescope of Huygens, it proved fully a match for the refractor, except that the latter showed objects somewhat brighter. After this period reflectors came rapidly into general use, and have ever since been the favorite kind of telescope in England. Their construction was greatly facilitated to practical men by the appearance in 1777 of an elaborate memoir by Mudge, giving a detailed account of his process of making and finishing specula. Another important memoir upon the same subject, by the Rev. John Edwards, was published in the appendix to the "British Nautical Almanac" for 1787. (See SPECULUM.)—About 1766 a small telescope, only 2 ft. long, fell into the hands of a German organist residing in Bath, England. He sent to London for a larger instrument, and, finding its cost too great, undertook to make one for himself. That organist was the elder Herschel. He devoted all the time at his command to the manufacture of reflectors. Improving continually upon his successive results, and with increasing means at his disposal, he made many Newtonian reflectors, some even as large as 20 ft., as well as several of the Gregorian form of 10 ft. focus. His discovery of the planet Uranus, in 1781, brought him to the notice of George III., by whose liberality he was enabled in 1785 to undertake the construction of the celebrated 40-foot reflector, which was pronounced fin-

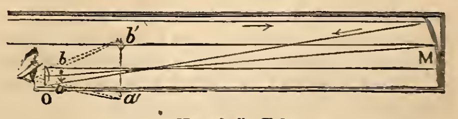

FIG. 5.—Herschel's Telescope.

ished in August, 1789; but it never accomplished any work worthy of its dimensions. In it the mirror M, fig. 5, was slightly inclined,

so that the image of the object was formed at $b\ a$, near the eye lens O, which magnified it into $b'\ a'$. It is commonly said that the sixth satellite of Saturn was discovered with it; but this is a mistake, the satellite having been in reality detected with one of Herschel's 18-inch reflectors. After the lapse of 50 years, during the latter portion of which the telescope had lain unused, it was dismounted by Sir John Herschel at the end of 1839, and on New Year's eve his family assembled within the tube and sang its requiem. It now rests horizontally upon three stone pillars, a monument to the memory of its constructor.—Newton evidently conceived that the prismatic rays of light, once separated, could not be recomposed into white light except by the same refraction that had separated them, and that therefore the removal of these colors from a telescopic image was impossible. The weight of Newton's authority was sufficient for a time to repress further investigations in this direction; and it was not till 1729 that an Englishman named Hall, guided, it is said, by a study of the mechanism of the eye, was led to a plan of combining lenses so as to produce an image free from colors. Telescopes were made according to his directions, and were said to perform well; but the secret of their construction died with him, and no public account of the facts was given until called forth by later occurrences. In 1747 Euler, referring to the construction of the human eye, declared that a combination of lenses of different media was possible which should give a colorless image, and investigated analytically the curvatures for a lens compounded of glass and water. His result was questioned by the man from whom opposition might have been least expected, John Dollond, who, relying too implicitly upon Newton's dictum, was contending against his own future fame. But he was soon led to consider the subject more attentively by the remark of a Swedish mathematician, that there were certainly some cases to which Newton's rules did not apply. He undertook experiments, at first with prisms of glass and water, and soon found that when the prisms were so combined that the rays passed through without refraction, they were tinged with the colors; next, arranging the prisms so that the rays appeared without colors, he found them displaced by refraction. He arrived at the same results by using prisms of crown and flint glass. From prisms to lenses the transition was easy, and his triumph was finally completed, when, having combined a convex lens of crown glass with a suitable concave of flint, he was able to correct the colors and leave sufficient refraction outstanding to produce a telescopic image. Euler still believed all kinds of glass alike in their optical properties, and that it was only some happy combination of curvatures at which Dollond had arrived; but his doubts soon gave way before experience, and the masterly powers of his analysis were brought to bear successfully upon the problem of the compound object glasses. The subject attracted universal attention, and mathematicians everywhere contributed toward perfecting by theory the requisite conditions of curvature of the lenses. The new telescopes were called achromatic, or free from color, and henceforth the "dispersive power" of any medium, by virtue of which the differently colored rays are differently refracted (that is, are dispersed from each other), was recognized as independent of the "refractive power," by virtue of which the whole pencil is diverted from its original source. Attempting, in 1758, to make double object glasses of short focal distance to be used with a concave eye lens, Dollond found difficulties in the management of the spherical aberration, and thereupon the idea occurred to him of dividing this aberration by having two lenses of crown glass and including the flint lens between them; an arrangement which accomplished the purpose in view, but did not succeed with convex eye pieces also. His son Peter resumed these experiments, and presented to the royal society of London a triple object glass of 3½ ft. focal length and 3¾ in. aperture, with which the telescopic image was pronounced by Short, an excellent judge, to be "distinct, bright, and free from colors." A beautiful suggestion was made by Wollaston of a means of testing and correcting the concentric adjustment of lenses. By removing the eye glass of a telescope and viewing any bright object, as a lighted candle, through the object glass, there may be observed at the same time with the refracted image a series of fainter images formed by the second reflections from the different surfaces. It is evident, then, that if the glasses be truly centred, these images will all be in the same straight line; or if there be any error of position of either lens, it will be decidedly manifested, and by proper adjusting screws may be corrected accordingly.—Among the many mathematical solutions of the new problem of the object glasses were the precepts given by Klügel, in his "Dioptrics," viz.: 1, that the radii of curvature of the first, or crown lens, should be such that the angles of the incident ray with the normal would be equal at both surfaces, which would give for crown glass a ratio of nearly 1 to 3; 2, the radius of the third surface, the first of the flint lens, should be such that the rays of mean refrangibility passing through both the centre and edge of the lens would unite as nearly as possible in the same part of the axis, so that the spherical aberration would be sensibly destroyed; and 3, having determined the outstanding dispersion for the red and violet rays, the fourth surface should be made such as to unite these rays as nearly as possible in the same point with the rest. Early in 1816 Bohnenberger, commenting upon these precepts, showed that, by changing the ratio of the first two surfaces from $\frac{1}{3}$ to $\frac{2}{3}$, the proportion of aperture to focal length could be materially increased without prejudice to

the performance of the instrument. Not long afterward Gauss remarked that it was possible, theoretically, to construct an object glass which would unite all the rays of any two colors as well as the mean rays at the centre and at a given distance therefrom into one and the same point. Both lenses should be concavo-convex. With a proportion of aperture to focal length of $\frac{1}{13}$ he obtained an almost perfect union of rays. The unusually deep curvatures of the lenses seem to have occasioned some scruples on the part of opticians, and this construction remained almost forgotten for 40 years, until Steinheil found and conquered the practical difficulty, and in 1860 arrived at complete success in the manufacture of the Gaussian object glasses.—The proper construction of eye pieces was also a matter of some consideration. Besides the Huygenian form, which is only applicable for viewing objects, Ramsden in 1783 introduced another, which is still used in micrometer observations. It consists of two plano-convex lenses, of equal focus, with their convex surfaces toward each other, and separated by a distance of two thirds of the common focal length. By this arrangement, to which he was guided by a remark of Newton, the essential condition of a "flat field" is gained, and the aberrations, chromatic and spherical, are so much reduced as to be practically insensible. For terrestrial observations, the elder Dollond sought to reduce aberrations and enlarge the field of view by increasing the number of lenses, and, after improving the four-glass eye pieces already in use, obtained by adding a fifth lens a combination which very satisfactorily effected both the desired objects.—Joseph Fraunhofer studied the theory of light and the laws to which it is subject in transmission through various media, and solved the difficulty of procuring disks of homogeneous flint glass. The process by which his glass was manufactured is kept a secret, but it is generally understood that the disks themselves are obtained by selecting and melting together the most faultless specimens from larger masses of the best glass, whose constituent parts however are not known. Having now the glass, he well knew how to combine curvatures to suit its peculiar properties, and the results are to be found all over Europe. He completed in 1824 the splendid telescope for the observatory at Dorpat. The object glass of this instrument, double and not triple as sometimes stated, has a clear aperture of 9·6 in., and a focal length of 170·5 in. Its optical performance is of the highest character. It gave to the stellar images a perfect sharpness of definition, which enabled it not only to resolve the closest known double stars, but also to discover as double or multiple others that had passed unchallenged before the exquisite 20-foot reflectors and the practised eye of the younger Herschel. Fraunhofer's style of "mounting" the telescope remains to this day essentially unimproved.—The manufacture of optical glass has received much attention in England. In 1824 a committee was appointed by the royal society to take into consideration the theory and to experiment upon the manufacture of such glass. The chief labor devolved upon three members, G. Dollond, Faraday, and Herschel. The first results were reported to the society in 1829. The efforts of this committee were directed to the manufacture of very heavy glass, and they obtained disks of 7 in., which seemed, so far as tried, to answer all the requirements of the telescope. Dr. Ritchie also devoted much attention for several years to the same subject, and with considerable success, but was prevented by premature death from publication of any of his processes. Judging by the appearance of Ritchie's glass, Mr. Simms inferred that it had been fused in moulds and there subjected to pressure. The largest disk had 7¾ in. diameter, and was ground for use by Simms himself. It was found to be "an excellent glass, but not altogether faultless." The idea occurred to some that the desired achromaticity might be obtained by separating the lenses and placing the flint at some distance down the tube in the narrowing cone of rays. In 1828 Alexander Rogers proposed to introduce in combination with the crown lens a smaller compound lens of plate and flint glass, in which the refraction is entirely destroyed, and the outstanding dispersion left available for the desired correction of that of the outer lens. The investigation of the requisite curvatures of this compound lens was found to present no peculiar difficulty; and moreover the final perfection of the compensating action could be accomplished by proper adjustment of the relative positions of the lenses, so that less rigorous accuracy is requisite in their mechanical formation. Rogers found it probable that a telescope of 18 ft. focal length, with a crown lens of 12 in. aperture, could be made achromatic with a flint lens only 4 in. in diameter; and four years later this construction was introduced into use by Plossl at Vienna with much success. It received the name of "dialytic" or separated telescope. One of these telescopes, in the possession of Schumacher, having an aperture of 2¼ in. and focal length of 2 ft., was described by him as of extraordinary excellence of defining power. Struve compared a dialytic telescope of 3¼ in. aperture, bearing a magnifying power of 135, with a Fraunhofer telescope of half an inch greater aperture and a power of 210, and was scarcely able to perceive any superiority in the latter. Telescopes with lenses of rock crystal and glass were advertised to be made in Paris by Cauchoix in 1831, and some few came into favorable notice; but the difficulty of obtaining the materials in proper shape and size will be a permanent obstacle to their general manufacture. It had long been observed that, even in the best telescopes, there were residual colors hav-

ing their origin in the want of a perfect correlation of the colored spaces in the spectra formed by the crown and flint lens; so that if any two colors be made to unite at the same focus, as in ordinary object glasses, there would not be at the same time a complete union of the rest. This want of correlation is called the "irrationality" of the colored spaces, and its effect is called the "secondary spectrum." Dr. Blair, to overcome this effect, first made each of the lenses of his object glass independently achromatic, and in such a way that their secondary spectra corrected each other. This he accomplished by using fluid media, two lenses of which were enclosed in combination with three of glass. Moreover, in the course of his experiments, he discovered that muriatic acid combined in proper proportions with metallic antimony gave a spectrum in which the colors had exactly the same proportions as in crown glass; and therefore by enclosing this fluid between two crown lenses, one a plano-convex and the other a meniscus, he obtained a telescope absolutely free from colors. The name "aplanatic," or without error, was given to this combination. Another fluid-lens telescope, of the dialytic form, was constructed by Barlow, who made use of the high dispersive power of sulphuret of carbon, a beautifully transparent and colorless fluid. He was able to render achromatic a combination of a crown lens 8 in. in diameter with a fluid lens of half the size. There is however a practical objection to the use of sulphuret of carbon arising from the variability of its density by variations of temperature.—Reverting to what may be called the regular construction of achromatics, we find that the successors of Fraunhofer at Munich, and Guinand and Cauchoix at Paris, have produced object glasses of dimensions far superior to those of the Dorpat lens. Disks of 10, 12, and even more inches in diameter have become familiar to these master opticians, whose skill in working them keeps even pace with their manufacture; and in three Munich telescopes, two with more than 15 in. of clear aperture, one at Pulkova, another at the observatory of Harvard college, and the third at Greenwich (aperture 13 in.), have been in use for years. The two former have been the means of adding largely to the stores of astronomical knowledge; the Greenwich telescope has not been much used. —The few attempts made in the United States to manufacture optical flint glass have hitherto been but partially successful, and that with only small disks; but the American-wrought object glasses have earned for themselves a high place. Many have been made in New York by Henry Fitz, whose largest glass, 13 in. in diameter, was made for the Dudley observatory at Albany. Spencer, famous for the excellence of his microscopic objectives, made for Hamilton college a 13½-inch telescope, which is highly commended. But in exquisiteness of workmanship and performance, the object glasses made by Alvan Clark of Cambridge, Mass., have fairly distanced all competitors, native or foreign. Whoever will glance over the list of close double stars discovered with his 7- and 8-inch lenses (see "American Journal of Science," vols. xxv. and xxix.) will remark several stars that must have passed unnoticed under the review of Struve with his superior optical power. (See CLARK, ALVAN.) Mr. Dawes, one of the most skilful astronomical observers of his day, took in succession five or six large refractors from Clark (disposing of each in favor of a successor including some improvement of construction which had suggested itself), and these, scattered throughout England, attested the skill of the American optician in the special work of figuring object glasses, in which at present he and his sons are unrivalled. In 1859 Clark began the construction of a magnificent object glass of 18¾ in. clear aperture and with a focal distance of 23 ft., at that time the largest in the world. It was made from disks of Birmingham glass, which have a uniform density and freedom from veins, and, though only rudely mounted at first, quickly revealed the duplicity of the minute companion of $\alpha^2$ Capricorni. In January, 1862, it detected a companion to Sirius, perhaps the hitherto invisible one whose workings have been indirectly manifested in the variable movement of the larger star. This masterpiece, prevented from reaching its original destination, was secured for the Chicago observatory. In 1870 Clark was authorized by congress to begin the construction of a telescope 24 in. in aperture for the Washington observatory; but before the work was entered upon, the proposed aperture was changed to 26 in., Mr. Newall of Gateshead, England, having had a glass constructed for him by Cooke and sons, York, of the hitherto unequalled aperture of 25 in. The disks of glass, obtained by Clark from Chance and co. of Birmingham, reached Cambridge, Mass., in December, 1871, and the grinding was begun in January, 1872. "Owing to the great size of the glasses," says Prof. Newcomb, "the first rough grinding was done by machinery, the 'grindstone' being a rapidly revolving iron wheel, over which a stream of water and sand was kept running. The glasses were thus roughly brought to the desired shape in a few days. The forms chosen were much more simple than those usually employed in large glasses, the crown glass being double convex, with an equal curvature on each face; the flint nearly plane on one side, while the other was concave, with the same curvature as the crown glass. . . . In the month of June, 1872, the glass was in such good shape that only an expert could see any defect whatever. Looking through it we could read, at the distance of some 400 ft., a microscopic photograph illegible to the naked eye. . . . Artificial double stars, one third of a second apart, were clearly separated. In hands less severely critical than those of the

makers it would have passed as optically perfect. Nevertheless four months more were spent on it, and it was not till October that it was reported finished. . . . The influence of temperature on its figure was now quite perceptible. In the evening, while temperature was falling, the defect of the spherical aberration was one way, but after it became stationary the defect was slightly in the opposite direction." The telescope was mounted at Washington in 1874, and though as yet it has achieved no noteworthy discovery, the ease with which it has gone through the work which had been usually regarded as closely testing the powers of the largest telescopes shows what it is capable of.—In England, the attention of the mechanical astronomers, if we may so call them, has been of late years more especially occupied with the construction of large reflecting telescopes, and preëminent in this department was Lord Rosse, who about 1844 completed a telescope which has a clear aperture of 6 ft. and a focal length of 53 ft. This enormous instrument has two specula, one about $3\frac{1}{2}$ and the other about 4 tons in weight. At first each rested upon a system of 27 platforms most ingeniously arranged to distribute their support of this enormous weight in such a manner as to produce equal pressure in every position of the instrument. A strong pressure of the hand at the back of a speculum 4 tons in weight and nearly 6 in. thick produces flexure sufficient to distort the image of a star. At a later period 27 triangles, each with a ball at each angle, were substituted for the platforms, so that now the speculum rolls freely on 81 balls. The tube of the telescope is supported upon a massive universal joint of cast iron resting upon a pier of stonework, and it is so counterpoised by a chain suspension applied at the centre of gravity that it can be moved with great facility, a quick motion being given by a windlass below, and a controlling slow motion in either direction by the hand of the observer above. Various micrometers have been tried with this instrument, but the common filar micrometer with coarse threads answers best; and such is the quantity of light collected by the immense reflecting surface below, that the threads in the micrometer are always distinctly visible without artificial illumination even in the darkest night. The general processes of casting, grinding, and figuring these large specula are described in the article SPECULUM. Several other large reflectors have been constructed by Lassell, De la Rue, and Nasmyth; and the first of these transported to Malta a Newtonian telescope 4 ft. in diameter. De la Rue successfully applied his large telescopes to celestial photography, in which he has made many important improvements.—The manufacture of reflecting telescopes with glass specula received a new impulse from the discovery by Liebig of a process of coating glass with an infinitesimal film of pure metallic silver. From the first days of reflectors, as early as Newton, we find a proposition to substitute a silvered lens for the metallic mirror of his telescope, on account of the greater perfection with which glass could be wrought, and the greater durability of the polished surface. In 1740 Caleb Smith showed how, with glass mirrors silvered upon the posterior surface, the rays of different refrangibility, after twice passing through the glass, and thus becoming separated, might be united again by the action of a small concave lens placed not far from the focus of the mirror. The elder Herschel sometimes used glass reflectors for his smaller telescopes. In 1822 Airy proposed a combination of two silvered lenses in the Gregorian or Cassegrainian form, and showed how, by proper mutual adjustment of the two, a perfect achromatism might be obtained. In 1838, and again in 1841, Barfuss of Weimar found that, of the various forms of reflectors, the Cassegrainian was best adapted for glass mirrors. He demonstrated that in this form both chromatic and spherical aberration may be sensibly corrected in a telescope of 20 in. focus with full 5 in. aperture, and that such a telescope would bear even a power of 600. But by Liebig's discovery a still better field has been opened. His process consists in precipitating the silver upon the glass surface from an alkaline solution prepared by addition of caustic soda to the ammonio-nitrate. After immersing the glass for about three quarters of an hour, an extremely thin and regular film is obtained, which has a slight bronzy hue by reflected light, and will transmit a deep blue light when interposed between the sun and the eye. This film is said to be harder than ordinary silver, and, by friction with soft leather and perhaps a little dry rouge, is susceptible of receiving the most brilliant polish externally, while it answers perfectly in figure to that of the glass beneath. Foucault has also made use of a similar process (see SPECULUM), and succeeded in constructing telescopes of considerable dimensions. One was made by him of 13 in. aperture and only 88 in. focus, with which, under a magnifying power of 600, he could separate the components of the small companion of $\gamma$ Andromedæ. Steinheil, investigating the relative reflecting power of a speculum coated by this new process, as compared with others and with the transmitting power of some object glasses, found that, under an angle of reflection of 45°, the amount of brightness obtained was as follows:

| | |
|---|---|
| Direct light | 100 |
| Silvered mirror | 91 |
| Quicksilvered glass | 76 |
| Metallic mirror, one reflection | 67 |

Herschel gives also:

| | |
|---|---|
| Newtonian telescope | 44 |
| Gregorian or Cassegrainian | 40 |

Steinheil:

| | |
|---|---|
| Object glass by Fraunhofer transmits | 76 |
| Object glass by Steinheil | 87 |

We are now able to substitute for the heavy and intractable speculum metal a disk of glass which is far easier to cast and anneal, and being much firmer can be made of less than half the weight of the metallic mirrors.—The helioscope, for observing the sun, is a telescope with the aperture diminished as much as possible, and usually provided with shades of stained glass to protect the eye. Still, great inconvenience is felt from the intense heating power of the concentrated solar rays. Sir John Herschel proposed to use only the very small portion of light reflected from the first surface of glass, by constructing the large mirror of a Newtonian telescope of a double-concave, well polished lens, whose first surface only is truly figured to serve as reflector for the 2·6 per cent. of rays untransmitted and unabsorbed. The lower end of the telescope tube being left open, all the remainder of the light passes out and is dispersed. But even the small amount of reflected rays is still further reduced by the second reflection, which is made to take place at the first surface of a prism whose refracting angle should not be less than 30° or 40°, so that now the portion of light finally reaching the observer is but $\frac{1}{1300}$ of the direct illumination, in consequence of which immense reduction a very light shade only is needed. Porro of Paris, in constructing a telescope upon this principle, improved it by placing the prism for the second reflection at the polarizing angle for glass, whereby, upon introducing a Nicol's prism, the light may be enfeebled as much as desired without using any shade at all.—The great requisites of a telescope stand are firmness and stability, combined with a facility of motion which will allow the instrument to be pointed with ease and certainty to any part of the heavens. Fraunhofer, whose plan is now generally followed, adopted the equatorial form, as it is called, which consists essentially of a polar axis upon which the whole instrument is moved parallel with the celestial equator, and which carries in a socket another axis at right angles to itself, upon which latter the telescope moves from or toward the pole. By the combined motions command of the whole visible hemisphere is given, and with the advantage that, the instrument being once directed to a star, the observer can follow it in its diurnal path by motion upon the polar axis alone; moreover, by application of a simple train of wheelwork this motion can be effected by machinery, and the observer is thus enabled at his leisure to contemplate or to measure the objects which appear fixed as though in an immovable sky. In the immense English reflectors, the lower end of the tube rests upon the ground or some solid support, and even then for the needful motions of the instrument powerful appliances of machinery have been required; but in latter days mechanical engineers have been able so to combine and counterpoise great masses of cast-iron machinery as to effect with wonderful ease every delicate movement desired by the astronomer, and now the idea of mounting even these large telescopes equatorially is growing familiar. The application of clockwork movement to such large reflectors renders it practicable to use them for celestial photography, as well as for some extremely delicate astronomical measurements.—The application of the telescope to meridian instruments will be exemplified in the article TRANSIT CIRCLE; but the telescope is also universally used for differential measurements. For such observations various modifications or appliances have been from time to time suggested or practised. The filar micrometer is the most common auxiliary of the telescope, and in skilful hands is capable of astonishing accuracy. (See MICROMETER.) Great use has also been made of the power of producing and comparing together double images of the objects to be measured. These double images are produced in various ways. Savery in England in 1743, and Bouguer in France four years later, proposed, independently of each other, to measure the diameter of the sun by using two object glasses in the same telescope and with the same eye piece. In Savery's plan the glasses were all fixed so as to give two images of the sun whose outer edges were nearly in contact; and by measuring the variable distance of these edges, he obtained the corresponding variations of the semi-diameter from perigee to apogee. Bouguer made one of his object glasses movable, and thus could measure any angle from zero to his maximum limit, which was probably somewhat greater than the sun's diameter. In 1753 John Dollond invented the divided-object-glass micrometer, which has in later years, under the technical name of heliometer, achieved such wonders in the hands of Bessel and his followers. In this instrument the object glass itself when finished is divided into two equal segments, each of which forms its image independently of the other. When the semi-lenses are brought to their normal position of coincidence, the two images coincide also; but when separated, the images diverge, and the angle of divergence is measured by the amount of separation of the lenses. Thus the apparent diameter of a planet, for instance, is obtained by separating the images until their outer edges are in exact contact, and this may be more accurately perceived than the coincidence of the edge with a fine thread placed tangent to it as in the filar micrometer. Dollond proposed moreover to gain both accuracy and convenience of use by placing a divided object glass of very long focus before the speculum of a reflecting telescope, which would give a larger scale for the measurement of a given angle than would belong to a simple telescope of the same length. Fraunhofer was at the time of his death engaged in devising a heliometer which, when afterward completed, was placed at Königsberg. Bessel, whose "Theory of the Heliom-

eter" is one of the most elaborate and beautiful monographs of astronomy, was able with this instrument to grapple successfully with that even now most difficult practical problem, the measurement of the parallax of a fixed star. Several attempts have also been made, as by Rochon, Maskelyne, and Boscovich, to produce the double images by refraction through prisms or pairs of prisms, either beyond the object glass or sliding within the tube, as well as by dividing the small mirror of reflecting telescopes, as Ramsden suggested for the Cassegrainian form, and Brewster for the Newtonian. Divided-eye-lens micrometers have also been made, the best form of which is that given by Airy, who found the four-glass eye piece best adapted for this purpose, and divided the second lens, counting from the object glass. But in all the arrangements of divided lenses an essential imperfection arises from the exhibition of color and of some diffraction in the direction at right angles to that of the line of separation, and this practical inconvenience may be seriously felt in some classes of observations. On this account, it will probably yet be found most advantageous to make use of the double-refracting property of certain crystals for the separation of images.—This account would be imperfect without a sketch of the particular form of telescope employed by the American observing parties in photographing the recent transit of Venus. What was required was a large image of the sun at the focus of the object glass, or the principal focus as it is called. The size of this image is directly proportional to the focal length, and a focal length of about 40 ft. was required to give the image the desired dimensions. It would clearly have been impossible to provide telescopes of this length for distant stations, even if at Washington, Greenwich, or Paris instruments of such dimensions could be so driven by clockwork that the tube should remain constantly directed toward the sun. It became necessary, therefore, to make use of a heliostat, or plain mirror, so worked by a driving apparatus as to deflect the sun's rays constantly in the same horizontal direction. The construction of a plane mirror sufficiently true for this purpose was a task which fully taxed the skill even of Alvan Clark and his sons. "The slightest deviation from exactness," as Newcomb points out, "would be fatal; for instance, if a straight-edge laid upon the glass should touch at the edges, but be the 100,000th of an inch above it at the centre, the reflector would be useless." The mirrors were tested by observing objects through a telescope, first directly and then by reflection from the mirror. If they were seen with equally good definition in the two cases, it would show that there were no irregularities in the surface of the mirror; while if it were concave or convex, the focus of the telescope would seem shortened or lengthened. The first test was sustained perfectly, while the circles of convexity or concavity indicated by the changes of focus of the photographic telescope were many miles in diameter. During the total eclipse of April, 1875, the heliostat again came into play for photographic purposes, but unsuccessfully because of unwise arrangements. (See p. 905.)

**TELFAIR**, a S. county of Georgia, bounded S. and W. by the Ocmulgee and N. E. by the Little Ocmulgee river; area, 925 sq. m.; pop. in 1870, 3,245, of whom 1,145 were colored. The surface is level and the soil sandy, with extensive pine forests. The Macon and Brunswick railroad intersects the N. part. The chief productions in 1870 were 62,429 bushels of Indian corn, 15,823 of oats, 20,569 of sweet potatoes, 19,829 lbs. of wool, and 704 bales of cotton. There were 497 horses, 2,563 milch cows, 6,946 other cattle, 8,475 sheep, and 7,477 swine. Capital, Jacksonville.

**TELFORD, Thomas**, a British engineer, born at Westerkirk, Eskdale, Dumfriesshire, Aug. 9, 1757, died in Westminster, Sept. 2, 1834. While working in Edinburgh as a stone mason he studied architecture and drawing. In 1783 he removed to London, was employed on the quadrangle of Somerset house, afterward for three years as architect in the Portsmouth dockyard, then upon the alterations of Shrewsbury castle, and in the construction of numerous bridges, one of which over the Severn had a flat arch of 130 ft. span. He superintended the construction of the Ellesmere canal, 103 m. in length, and requiring extensive aqueducts, which he built of iron; the Caledonian ship canal, whose locks surpassed any previously built in size; and six other canals in England and Scotland, the Götha canal in Sweden, an immense tunnel at Harecastle on the Grand Trunk canal, besides 1,000 miles of new road and 1,200 bridges. The St. Katharine docks of London, the improvement of the Aberdeen and Dundee harbors, the construction of iron bridges with flat arches of 170 ft. span, and above all the Menai suspension bridge, were his work.—See "Life of Thomas Telford, Civil Engineer, written by Himself" (4to, with a folio volume of plates, 1838).

**TELIOSTS**, a name given by J. Müller to the common bony fishes from their well ossified skeleton; the term has been taken by Huxley for one of his orders. They comprise the ctenoids and cycloids of Agassiz.

**TELL, William**, a legendary hero of Switzerland. According to tradition, he was a hunter, living at Bürgelen in the canton of Uri. His wife was a daughter of Walter Fürst, who with Stauffacher of Schwytz and Melchthal of Unterwalden organized the conspiracy of the Grütli in 1307, and founded Swiss independence. Tell's part in the revolt against Austria is related as follows: Gessler, Austrian bailiff in Küssnacht, placed his cap upon a pole in the market place of Altorf, and gave orders that passers by should do it reverence. Tell neglected or refused to do this, and was arrested

and sentenced to death. But Gessler, hearing that he was a skilful marksman, told him his life would be spared on condition of his shooting an apple from his child's head. Tell ventured the shot, and succeeded without injuring the child. Gessler perceived that he had put a second arrow in his quiver just before shooting, and asked the object. Tell replied: "To kill you if I had harmed my son." For this he was again put in chains. Gessler then embarked for Küssnacht, taking Tell with him. On the way the boat was overtaken by a storm. The crew, fearing for their lives, begged Gessler to release Tell, that he might steer the boat. He complied, and as they neared the point now known as "Tell's Rock" or "Leap," Tell sprang ashore; but the most dangerous part of the coast had been passed, and the crew brought the boat safely to Brunnen. Meanwhile Tell went around by land, and, lying in ambush between Brunnen and Küssnacht, wounded Gessler mortally with an arrow. Gessler's death was the signal for a general uprising; the Austrian bailiffs were driven from the several cantons, and their castles destroyed. In 1315 Tell took part in the battle of Morgarten, and in 1354 was drowned in the Schächen while trying to save a boy's life.—Such is the story in its main features, as Schiller has embodied it in his drama. But recent historical investigations put it in a very different light. Schwytz, Uri, and Unterwalden struggled for autonomy against the Hapsburgs from 1240 to 1315, and later. The conflict seldom took the shape of armed hostilities; it was rather the gradual growth of local independence. We do not know the names of the leaders of the Swiss movement, but we do know that there was no conspiracy of the Grütli, that no such bailiffs as Gessler, Wolfenschiessen, and Landberg existed by those names, and no such men as Tell, Stauffacher, or Melchthal. A league was formed by Schwytz, Uri, and Unterwalden, but it was not a secret conspiracy, and it was formed in 1291 and not in 1307; and there was no uprising in 1308. Kopp (*Urkunden der Geschichte der eidgenössischen Bünde*, 1835), Huber (*Die Waldstädte bis zur Begründung ihrer Eidgenossenchaft*, 1861), W. Vischer (*Die Sage von der Befreiung der Waldstädte*, 1867), Rilliet (*Les origines de la confédération suisse*, 1869), and others, have shown how patriotic imagination in Switzerland, having lost the remembrance of the precise steps by which independence was obtained, has actually created the tradition in its present shape. The beginning was made by *Das weisse Buch*, a chronicle composed about 1470, in which first occur most of the names with which we are familiar. Then comes the *Tellenlied*, composed about the same time; then, in 1540, the *Hübsch Spyl* of Uri. But these and similar productions were all outdone by Ægidius Tschudi (1505–'72), in his *Chronicon Helveticum*. Tschudi seems to have gathered scraps of tradition wherever he could find them, to have expanded them and put them into the most plausible shape, and to have invented names, surnames, and even dates. Johannes von Müller and Schiller followed Tschudi. The popular version of the Swiss uprising, then, is to be regarded as a distortion of the facts, and its prominent persons and striking incidents are imaginative decorations added by generation after generation from the 15th to the 17th century. But Tell is the embodiment of a wide-spread Aryan myth. The Persian poet Ferid ed-Din Attar (about 1175) sings of a king who shoots an apple from the head of his favorite. Saxo Grammaticus, in his "Danish Chronicle" (about 1170), tells how Toko shoots an apple from the head of his son, by order of King Harold Bluetooth; here the incident with the second arrow is mentioned. In the Edda, Eigil the marksman is made by King Nidung to shoot an apple from the head of his son, and the incident with the second arrow again occurs. The name "Tell" has been variously explained. Grimm connects it with the Latin *telum*, an arrow; others with the German word *tall*, meaning half-witted. In *Das weisse Buch* Tell seeks to excuse his disrespect to the hat on the ground that he is dull of wit, saying, "Otherwise I should not be called the *tall*." According to Carrière, the Tell saga is neither history nor pure invention, but the reminiscence of ancient mythological poetry, recast and coupled with historical events. For a brief account of the Tell saga, see Carrière's edition of Schiller's *Tell* (Leipsic, 1871), and Buchheim's edition (London, 1871).

**TELL-TALE**, a bird. See TATTLER.

**TELLURIUM** (Lat. *tellus*, the earth), an elementary substance, discovered by Müller von Reichenstein in 1782, but first investigated and named by Klaproth in 1798; symbol, Te; chemical equivalent, 129; specific gravity, 6·65; hardness, 2 to 2·5. Though commonly classed among the metals, it has much analogy in its properties to sulphur and selenium. It fuses between 800° and 900° F., and can be distilled in a current of hydrogen. It is a bad conductor of heat and electricity. It occurs in a native state associated with iron pyrites and various metals, as gold, silver, bismuth, copper, or lead. The native metal is of a brilliant metallic lustre, of a tin-gray or lead-gray color, passing to steel-gray. It is very fusible before the blowpipe, and burns with a bluish flame, green on the edges; it volatilizes in white fumes, leaving no residue; and it is wholly soluble in nitric acid. The substance occurs in small masses, irregularly lamellar, and crystallized in six-sided prisms, at the mine of Maria Loretto near Zalatna in Transylvania. Its most common ore is the black, foliated mineral of Nagyág, which contains about 13 per cent. of tellurium in the form of tellurides of gold, lead, and silver, mixed with sulphides of antimony and lead. Tellurium is almost always combined with small portions of iron or gold

in a metallic state, silver, or lead, so that some have supposed that the substance ought to be considered as telluride of iron or of gold. Many natural alloys have been met with at the mines of Hungary and Transylvania, and from the collection of those presented by the emperor of Austria to the museum of natural history at Paris, Dufrénoy has arranged the varieties among the following five species: native tellurium, auro-argentiferous tellurium (graphic gold), auro-plumbiferous tellurium (müllerite), plumbo-auriferous tellurium (nagyagite), and telluric bismuth (tetradymite). Auro-argentiferous tellurium was recognized at the Gold Hill mines, North Carolina, and native tellurium at Red Cloud mine, Gold Hill, Boulder co., Colorado, by Dr. Genth; and telluric bismuth is found in many of the gold mines of Virginia and North Carolina, in foliated scales and lamellar masses. Gold and silver tellurides occur in masses on the Calaveras range in California. Tellurium forms two oxides, $TeO_2$, $TeO_3$, which correspond in composition to sulphurous and sulphuric anhydrides. Tellurous acid, $H_2TeO_3$, and telluric acid, $H_2TeO_4$, are analogous to sulphurous and sulphuric acids. With hydrogen it forms the gaseous compound $H_2Te$, analogous to sulphuretted hydrogen.

**TELLUS.** See TERRA.

**TEMES,** a S. E. county of Hungary, in the Trans-Tibiscan circle, watered by the Temes and Béga; area, 2,289 sq. m.; pop. in 1870, 356,174, mostly Roumans and Serbs, and about two thirds belonging to the orthodox Greek church. The soil is very fertile, but the climate is unhealthful. The chief products are wheat, maize, hemp, flax, fruit, wine, and cotton. Cattle, sheep, pigs, and bees are raised.

**TEMESVÁR,** a city of Hungary, capital of the county of Temes, on the Béga canal, connecting it with the Danube at Belgrade, 75 m. S. S. W., and 155 m. S. E. of Pesth; pop. in 1870, 32,754, chiefly Germans. It consists of the town proper, which is strongly fortified, and four suburbs, including the village of Mehala. It has been much improved by the draining of marshes. It has fine Catholic and Greek cathedrals, a magnificent synagogue, an arsenal, a theological seminary, a Catholic gymnasium, and a normal school. Leather, cloth, and other articles are manufactured.—The origin of the city is traced to the Romans. The Turks held it, despite a number of sieges, from 1552 to 1716, when it was rescued by the Austrians, under whom it became the capital of the Banat. In 1849 it was besieged for several months by the Hungarians, who were signally defeated here on Aug. 9 by Haynau. A monument was erected in commemoration of this siege, during which the city suffered severely.

**TEMISCAMINGUE, Lake.** See OTTAWA, vol. xii., p. 734.

**TÉMISCOUATA,** an E. county of Quebec, Canada, bounded N. W. by the St. Lawrence river and S. E. by New Brunswick; area, 1,771 sq. m.; pop. in 1871, 22,491, of whom 21,809 were of French origin or descent. It is watered by the Trois Pistoles and Madawaska rivers and other streams, and contains Lake Témiscouata, 30 m. long and from ½ m. to 1½ m. wide, the source of the Madawaska. It is traversed by the Grand Trunk and Intercolonial railways. Capital, Isle Verte.

**TEMPE,** a valley of Greece, in the northeast of Thessaly, between Mts. Olympus and Ossa, celebrated in antiquity for its beauty. Poets and rhetoricians often mentioned it as a type of sylvan loveliness, and it was also famed as a haunt of Apollo. It was with laurel from Tempe that the victors in the Pythian games were crowned. The most accurate description of the famous pass is that of Livy. The lofty cliffs rise almost perpendicularly on either side, and the Peneus rushes through the middle of the valley. The defile is about 5 m. in length, and is so narrow in parts as to afford space only for the river and the road. Right and left are the ruins of ancient fortresses, and numerous tumuli are seen.

**TEMPERAMENT,** a term used to express the differences in the physical and mental constitutions of individuals, referred from remote antiquity to peculiarities in the quality of the solids and fluids of the body. The ancients believed that the fluids of the body consisted of four humors (corresponding to the four then so-called elements, earth, air, fire, and water), which they named bile, blood, black bile (supposed to come from the spleen), and phlegm or watery fluid (believed to come from the brain); and, if either of these elements was in excess, that it gave rise in the above order to the bilious or choleric, sanguine, melancholic, and phlegmatic temperaments. This view was maintained by physicians to the time of Cullen, who admitted only two temperaments, the sanguine and the melancholic. The sanguine temperament is marked by a predominance of the circulatory system, with a strong and frequent pulse, firm flesh, plump figure, smooth and fair skin, ruddy complexion, soft and light hair, and light eyes; there is great nervous susceptibility, ready memory, lively imagination, cheerfulness, and a love for sensual pleasures; its diseases are generally violent and inflammatory. In Cullen's melancholic temperament the solids predominate, the figure being less plump and more firm, the hair and eyes black, the skin coarse and dark, the countenance sallow and sad; the disposition is gloomy and the temper suspicious; the manner is slow, grave, cautious, and impassive. Other temperaments as well characterized as the above are the bilious, lymphatic, and nervous. The bilious or choleric temperament is marked by a supposed predominance of the biliary system, with strong hard pulse, yellowish brown skin and dark hair, and moderately fleshy body; by violent and easily excited passions, firmness and inflexibility of

character, boldness, and perseverance. In the phlegmatic or lymphatic temperament the flesh is soft, the skin pale and flabby, hair light, pulse weak, and the figure rounded, with little expression of countenance or activity of mind and body. The prominent character of the nervous temperament is a great excitability of the nervous system, and the preponderance of the emotions and impulses over the reason and will; the muscles are small and soft, and the form generally slender.

**TEMPERANCE SOCIETIES.** See TOTAL ABSTINENCE.

**TEMPERED GLASS,** a peculiar condition of glass which has recently been produced by M. de la Bastie of France, by subjecting it while hot to the action of a bath of prepared oil, in which it is enclosed to prevent ignition. This treatment appears to confer a certain degree of toughness to the exterior, which enables it to bear much harder blows than common glass. When broken, however, it crumbles into dust or small fragments, like Prince Rupert's drops, and it cannot like ordinary glass be cut with a diamond into regular forms, but crumbles under the instrument. An attempt to grind it, or to cut it with the sand blast to any depth, produces disintegration. This indicates that the molecules are held together under a condition of strain, and an optical examination supports the same conclusion.

**TEMPLARS,** or **Knights of the Temple** (Lat. *milites templi*), the most celebrated and powerful of the mediæval military orders of Christendom. Its origin dates from 1117, when two French knights, Hugues des Païens and Geoffroi de Saint-Adémar or Saint-Omer, took on themselves the obligation of escorting the pilgrims who continually journeyed between Jerusalem and the river Jordan. They were soon joined by seven other knights, and were permitted by the patriarch of Jerusalem to add to the three usual monastic vows a fourth binding them to defend the holy sepulchre and to protect pilgrims travelling through Palestine. They were generously befriended and encouraged in the beginning by the knights hospitallers of St. John. They were very poor, being called "the poor soldiers of the holy city;" and the two founders in their first excursions rode on one horse, a fact perpetuated on the great seal of the order. Baldwin II., king of Jerusalem, gave them a lodging in his palace near the traditional site of the temple, and the canons of the adjoining church granted them a house for an armory. Their number was not allowed to increase beyond nine till the council of Troyes, 1127–'8, which Hugues des Païens and five of his brethren attended, and which commissioned St. Bernard of Clairvaux to draw up a rule for them, and devise a habit suitable to their mode of life. This rule, approved by Pope Honorius II. in 1128, is divided into 72 articles, several additions having been made. It bound the knights to be present at the public canonical office, and when absent on military service to recite certain vocal prayers at the stated hours; they were to abstain from flesh meat four days in the week, and to refrain from hunting and hawking; each knight was to have three horses and a squire. Their oath, on making their religious profession, bound them to defend at the peril of their lives the mysteries of the Christian faith, the seven sacraments, the 14 articles of belief, the Apostles' and Athanasian creeds, the Old and New Testaments with the interpretations of the fathers as approved by the church, the unity of the divine nature and the trinity of persons, and the virginity of the mother of Christ both before and after his birth; to perform military service beyond the seas whenever called upon to do so; and never to fly before three infidels, even when alone. The knights were given a white tunic and mantle to distinguish them from the hospitallers, the squires and servitors wearing black or the colors common to the country; and in 1146 they were permitted to wear a red cross on the left breast, the hospitallers wearing a white cross on their black mantles. Their banner was of white linen striped with black, and was thence called *beauséant*, the name given at the time to a horse marked with black and white, and *beauséant* became also the battle cry of the order; the red cross was added in 1166. Their helmet, in token of humility, had no crest, and their beards were uncut. The members were classed into knights, squires, servitors, and later chaplains, who were priests of noble birth. On assuming the habit of the order all were girt with a cincture of linen thread, as a badge of their service. The order was divided into provinces, the provinces into priories or bailiwicks, and these into preceptories, composed of a single house or several houses in close proximity. Over the whole order presided the master or grand master, having as his lieutenant the grand seneschal, both of whom, as well as the grand marshal, treasurer, &c., were elected by the knights in general chapter. The provinces were governed by provincial masters, grand priors, or grand preceptors; and the inferior officers were designated respectively as priors or bailiffs and preceptors. The head province and residence of the grand master was Jerusalem, and its chapter in ordinary times was invested with all the powers belonging to the whole order assembled in general chapter. Pope Alexander III. allowed the order to receive priests as chaplains, without binding them by a military vow. They were *ex officio* secretaries to the local chapters, and were often appointed preceptors, but were not eligible to the higher offices. The order came in course of time to be designated as sovereign, the grand master owing no allegiance to any prince, and being solely dependent on the pope in spirituals. Their houses were privileged, the ordinaries having no jurisdiction over them; their churches and cemeteries were not liable to in-

terdicts; their properties and revenues were exempted from tithes and taxation; and no person who had made profession as a templar could leave the order, unless he entered another of stricter observance. Many persons sought to be affiliated with the templars without being bound by vows, in order to share these manifold exemptions. There were also *oblati*, who in return for these privileges pledged themselves to maintain the rights of the order, and *donati*, or children given from infancy to be reared and incorporated therein.—The warm interest taken by St. Bernard in the soldiers of the temple, his enthusiastic advocacy of their cause, the solemn approbation given to it by the council of Troyes and Honorius II., and the heroic services already rendered by its first members to the Christians of Palestine, made them at once favorites with the princes and peoples of Christendom. The little band of nine soon grew into as many thousands. St. Bernard, whom the templars always designated as their "father," addressed them in 1146, at the prayer of Hugues des Païens, a series of exhortations, in which he defines their duties and the virtues peculiar to their profession. But while detailing their recent services and their extraordinary increase, he mentions a circumstance pointing to an early cause of degeneracy: "that the greater number of the nobles who have joined the soldiers of the temple had been men stained by every species of crime, whose conversion, while ridding Europe of oppressors and scourges, gave defenders to Palestine." In the East, besides the province of Jerusalem, the order possessed those of Tripoli and Antioch; in the West were the provinces of France, Auvergne, Normandy, Aquitaine, Poitou, Provence, England (including Ireland and Scotland), Germany, Upper and Central Italy, Apulia, Sicily, Portugal, Castile, Leon, and Aragon. The French provinces were by far the most important, and gave to the order the great majority of its members, as well as its wealthiest possessions. So rapidly had these accumulated throughout Christendom, that Matthew Paris affirms that in the middle of the 13th century they held 9,000 manors. They became more interested in extending and guarding their possessions than in affording protection to pilgrims; and notwithstanding their unquestioned prowess and daring, their frequent feuds with the rival order of the hospitallers, and their open licentiousness and lust of gain, often injured the cause to which they had devoted themselves. They aided or thwarted the plans of campaigns at their pleasure, and frequently stained their knightly name and fame by open treachery, as in the sixth crusade under the emperor Frederick II., the partial failure of which was attributed to the machinations of the templars. During the gradual decline of the Christian kingdom in Palestine they endeavored by separate treaties with the Saracens to secure their own possessions in that country. After having their chief seat successively in Jerusalem (1118–'87), Antioch (1187–'91), Acre (1191–1217), and the Pilgrim's Castle near Cæsarea (1217–'91), they were nevertheless compelled at the final extinction of the Latin power in Palestine in 1291 to remove to the island of Cyprus, which they had purchased from Richard I. of England for 35,000 silver marks. Though driven out of the Holy Land, the organization evinced no signs of decay, and its extensive ramification throughout Europe drew upon it the suspicion and jealousy of princes, whose cupidity was also excited by its immense wealth. Under the influence of these motives, and irritated by his inability to tax the order, Philip the Fair of France determined upon its destruction, and induced Pope Clement V. to have a judicial inquiry instituted into the orthodoxy and morality of the order. Accordingly, in 1306 Jacques de Molay, the grand master of the templars, was enticed to Paris, and on Oct. 13, 1307, all the members of the order in France, including De Molay himself, were taken into custody, and their houses and goods were everywhere seized. The formal charges imputed to them grave heresies and idolatry connected with their secret rites of initiation and internal discipline, and graver violations of morality; but there was no evidence of these beyond their own confessions, wrung from them by torture. The pope hesitated to promulgate the decree for the extinction of the order; but Philip procured one of his creatures, the archbishop of Sens, whose jurisdiction extended over Paris, to convoke his provincial council in that city on May 10, 1310; and on the 13th of the month, by command of that body, 54 members of the order were burned at the stake in a field behind the abbey of St. Antoine. The example was imitated elsewhere, and on May 2, 1312, Clement on his own responsibility, the general council of Vienne then in session being averse to precipitate measures, issued a bull for the abolition of the templars. In it he expressly declares that he does not pronounce "a definitive judgment" on the guilt of the templars, the charges against them not being proven; but that to prevent the further growth of a monstrous scandal, and for the greater good of Christendom, he suppresses the order, reserving to the holy see a final judgment as well as the disposition of the persons and property of the members. Their movable property was for the most part appropriated by the sovereigns of the countries in which it was deposited; and although their landed possessions were nominally transferred to the hospitallers, the crown as a general thing secured the disposition of them. The order ceased at once throughout Christendom except in Portugal, where it assumed the name of the knights of Christ, which order still subsists. Finally De Molay, Guy of Auvergne, and other high dignitaries of the order were burned at the stake, March 18, 1314.

**TEMPLE, Frederick**, an English bishop, born Nov. 30, 1821. He graduated at Oxford in 1842, and was elected fellow and mathematical tutor of his college. In 1846 he took orders, in 1848 was appointed principal of the training college at Kneller Hall, near Twickenham, in 1855–'7 was an inspector of schools, and in 1858 was appointed head master of Rugby school and chaplain in ordinary to the queen. In 1860 he contributed the first of the essays ("On the Education of the World") in the volume known as "Essays and Reviews." In 1868 he supported Mr. Gladstone's measures for the disestablishment of the Irish church, and was nominated bishop of Exeter, and consecrated on Dec. 21, 1869. He has published "Sermons preached at Rugby School, 1858–'69" (3 vols., 1861–'71).

**TEMPLE, Richard Grenville**, earl, an English statesman, born Sept. 26, 1711, died at Stowe, Buckinghamshire, Sept. 11, 1777. He was the eldest son of Richard Grenville and Hester Temple, and in 1752 succeeded his mother, who had been created in 1749 Countess Temple, as Earl Temple. The marriage of his sister Hester Grenville with William Pitt, afterward earl of Chatham, was the means of introducing him to public life, and during the first Pitt administration he was a prominent member of the cabinet. In 1852–'3 appeared "The Grenville Papers" (4 vols. 8vo), comprising the correspondence of Earl Temple and his brother George Grenville between 1742 and 1777, edited by W. J. Smith. The present representative of the Grenvilles is the duke of Buckingham and Chandos.

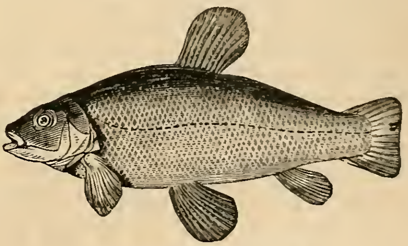
**TEMPLE, Sir William**, an English statesman, born in London in 1628, died at Moor Park, Surrey, Jan. 27, 1699. He was the son of Sir John Temple, master of the rolls in Ireland. After passing two years at Emmanuel college, Cambridge, he went abroad without taking a degree, and made the continental tour. He was married in 1654, and for several years resided with his father in Ireland. He represented the county of Carlow in the Irish convention in 1660, and also in the first Irish parliament after the restoration. In 1663 he removed to England, and in 1665 was sent on a secret mission to the bishop of Münster. In reward for his services, he was created a baronet and appointed resident at Brussels. In 1667 he visited Holland, and urged upon his government the necessity of a league with that country against the projects of Louis XIV. Receiving, in January, 1668, the necessary powers to negotiate such a treaty, he concluded the triple alliance between England, Holland, and Sweden, by which the contracting parties bound themselves to endeavor to bring about a peace between France and Spain, and to keep the former power out of the Low Countries. After perfecting at Aix-la-Chapelle negotiations for peace in pursuance of this alliance, he went in August, 1668, as ambassador to the Hague. Recalled to England in September, 1670, he discovered that the ministry had formed a secret treaty with France, by which the triple alliance was rendered of no effect, and in June, 1671, received his dismissal. For two or three years he resided at his estate of Sheen; but in 1674 he was summoned to negotiate a peace with Holland, which he accomplished in London. He returned soon afterward to his former post at the Hague, and was also one of the mediators deputed to attend the congress of Nimeguen, which resulted (1678) in an unsatisfactory treaty of peace between France and Holland, which Temple refused to sign. Returning to England, he declined to accept the office of secretary of state; but Charles II., harassed by the violence of parliament, gladly availed himself of Temple's advice, and his plan for a new privy council of 30 members, 15 to be great officers of state and 15 independent noblemen and gentlemen of great weight and landed possessions, was carried into effect in April, 1679. But in consequence of several perversions of its fundamental principles, and the admission of Lord Shaftesbury as a member contrary to his advice, Temple ceased to attend the regular meetings. A single session of parliament, to which he had been elected from the university of Cambridge, satisfied him with legislative life; and his name being stricken from the list of privy councillors in 1680, he thenceforth lived in retirement, either at Sheen or at Moor Park, a seat in Surrey. During the last ten years of his life Jonathan Swift was his secretary. His works comprise "Observations upon the United Provinces of the Netherlands," essays on the "Origin and Nature of Government," "Ancient and Modern Learning," "Gardening," &c., and a variety of political and miscellaneous tracts. His collected works were first published in 1720, edited by Swift; the last and best edition is in 4 vols. 8vo (London, 1814).

**TENANT.** See Lease, and Tenure.

**TENASSERIM**, a commissionership of British Burmah, on the E. side of the bay of Bengal, extending 650 m. from N. to S., with a breadth of from 30 to 80 m., between lat. 10° and 19° 30′ N., and lon. 95° 30′ and 99° 30′ E., bounded N. by Burmah, E. by Siam, S. by the Malay peninsula, and W. by the bay of Bengal, gulf of Martaban, and the administrative division of Pegu, from which last it is partly separated by the river Salwen; area, 46,730 sq. m.; pop. in 1872, 576,765. The country is divided into the districts of Amherst, Tavoy, Mergui, Shwegyen, Salwen, and Toungoo (which till recently was a division of Pegu); and the chief towns are Amherst, the capital, Maulmain, Martaban, Tavoy, Mergui, and Tenasserim. The sea coast of Tenasserim is about 500 m. in length. S. of lat. 11° 40′ it is bold and rocky, while further N. it is flat and much indented with bays, creeks, and estuaries. Along its whole extent are situated islands which appear from seaward to form part of the shore. Those lying S. of lat. 14° 40′ N. are known collec-

tively under the name of the Mergui archipelago. They vary greatly in form and dimensions, and are mainly situated from 30 to 80 m. off the shore. The most important island on the coast, however, is Balugyun, opposite the town of Maulmain, 17 m. long and 8 m. broad. The territory of Tenasserim is generally hilly or mountainous. It is intersected by numerous rivers, particularly toward the north, the principal being the Salwen, Attaran, Tavoy, and Tenasserim. The area of the basins of the rivers is estimated at about 14,000 sq. m. The E. boundary is formed by a range of wooded mountains varying in height from 3,000 to 4,000 ft. above the sea. In the north there is a separate range, about 2,000 ft. high, covered with bamboo jungles. There are extensive plains and fertile valleys lying upon the banks of the northern rivers. The staple productions are rice, cotton, sugar cane, indigo, and tobacco; and wheat, nutmegs, spices, and dye stuffs are raised. The country is exceedingly rich in valuable forest trees, prominent among which is the teak. Nearly 380 different varieties of timber have been enumerated. The timber forests are under strict and careful governmental control. Tin is mined, and iron, gold, and antimony are also found. Coal of good quality has been discovered in several places. The climate is considered remarkably healthful, the rate of mortality among Europeans being little more than it is in Europe under like circumstances. The thermometer rarely rises above 90°, the average being 77°. The rainy season begins in the S. part of the territory about the 1st of May, and at Maulmain a month later; the rainfall is much greater toward the north, where it is estimated at 200 in. a year. The average for the whole country is not less than 100 in.—The population comprises Burmese, Peguans, Siamese, Karens, Seelongs, Hindoos from the Coromandel coast, half-caste Portuguese, Chinese, a few American missionaries, and the English officials and traders. The Burmese and Peguans are the most numerous; the Siamese are principally settled in the neighborhood of the Tenasserim river. The chief manufactures are cotton and silk goods, coarse pottery, and iron cooking vessels. Ship building is largely carried on at Maulmain, and to a less extent at Mergui and Tavoy. These three places are the principal ports of Tenasserim, in regular steamship communication with each other and the Indian peninsula. The chief exports consist of rice, tobacco, gambir, ivory, edible birds' nests, and teak timber.—The Portuguese visited the territory which forms the Tenasserim division early in the 17th century; and in 1687 some English were massacred at Mergui, the country being then a dependency of Pegu. It afterward became subject to Siam, from which power it was taken about the middle of the 18th century by the Burmese, who held it till it was annexed to British India at the termination of the Burmese war in 1826. From the long unsettled state of the country, the entire population at that time amounted only to about 30,000; and its subsequent rapid increase is attributable to the security for life and property afforded by British rule. The town of Tenasserim, on the river of the same name, in lat. 12° 2′ N., lon. 98° 55′ E., was formerly the capital, but is now largely in ruins.

**TENCH,** a soft-rayed, fresh-water fish of the carp family, and genus *tinca* (Cuv.), peculiar to the old world. The best known species is the *T. vulgaris* (Cuv.), rarely more than 14 in. long, of a deep yellowish brown, and sometimes golden and greenish; the dorsal and anal fins have no osseous rays, and the former is inserted behind the commencement of the ventrals; the teeth on the pharynx are compressed and club-shaped; scales very minute, covered with mucus; a very small labial barbel at each side of mouth; the body thick and broad, and the ventrals in the male much larger than in the female. It is spread over Europe and N. Asia, and is more or less abundant in the ornamental waters and ponds of Great Britain, but is not found much above lat. 60° N.; it prefers stagnant waters with a muddy bottom, concealing itself in winter in the mud in a torpid state; like the carp it is very tenacious of life; the food consists of worms and aquatic insects, with sometimes seeds and plants. The eggs are deposited in May or June; they are very minute, greenish, about 300,000 in a single female, and are placed among aquatic plants. In its natural state the flesh is not good, but is delicate when the fish are properly fed.



Common Tench (Tinca vulgaris).

**TENCIN, Claudine Alexandrine Guérin de,** a French woman of society, born in Grenoble in 1681, died in Paris, Dec. 4, 1749. She became a nun, and like her two sisters led a gay life at her convent, and after her transfer as canoness to a less strict monastery near Lyons she was accused of being *enceinte*. In 1714 she was absolved from her religious vows, and went to Paris to live in the home of her brother, the future cardinal and statesman, for whom she displayed a passionate devotion, which subjected her to odious insinuations. She worked steadily for his advancement, acquired a fortune through the financier Law, and was for short periods mistress of Cardinal Dubois and of the regent duke of Orleans. By the poet Destouches she became (Nov. 16, 1717) mother

of D'Alembert. (See ALEMBERT.) In 1726 she was arrested on a charge preferred against her in the will of La Fresnay, one of her many lovers, who had killed himself in her house, of having sought to destroy him; but the charge fell to the ground. After her speedy release she showed greater discretion, and confined herself more exclusively to her associations with Fontenelle, Montesquieu, and other scholars who attended her receptions, which were among the first of the kind in France. She published *Les mémoires du comte de Comminges* (1735); *Le siége de Calais*, a historical novel (2 vols., 1739–'40); and *Les malheurs de l'amour* (1747). Her correspondence with her brother, the cardinal, was published in 1790, and *Lettres au duc de Richelieu* in 1806. Her works have frequently been published together with those of Mme. de Lafayette. One of the best editions is by Jay and Étienne (5 vols., Paris, 1825).—See *Mémoires secrets de Mme. de Tencin*, by the abbé Barthélemy (Grenoble, 1790).

**TENDER,** in law, an offer to perform an act, for the performance whereof one person is bound to another. The obligation, and so the offer, may be to pay money or to deliver specific articles. If the tender be of money, it is effectual only when the demand is one of money, and is definite in amount, or is capable of being made so. Thus, a tender cannot be pleaded as a defence to an action upon a contract, unless the contract be one for the payment of money, as for rent; nor to an action for a tort, as for assault and battery. In short, wherever the claim is for unliquidated damages, the general rule is that no tender is admissible. In some of the United States, however, cases of involuntary trespass form an exception, founded partly on usage and partly on express statutory provisions. A tender may be by the defendant in person, or by a third person at his request; and it should be made to the creditor personally, or to some one authorized by him to receive the money. At common law, a tender must be made on the very day the money is due, if that day be made certain by the contract. But the statutes and usages of the states generally permit the tender to be made after that day, if before the action is brought; and in some it may be made after the action is brought. Tender is generally not good if made before the debt is due, but may in some cases be so if it includes interest up to the day of maturity.—A tender of money is not complete without production and offer of the money, unless the creditor expressly or impliedly waives the production. Thus it is said not to be enough in a plea of tender, if the plaintiff did not object to receive the money, for the defendant to prove that he had the money in his pocket, and said to the creditor that he had it ready for him, and asked him to take it. He ought to have produced and offered the money specifically. What amounts to a waiver on the part of the creditor is a nice if not difficult question. It seems from the cases that the creditor may not only waive the actual production of the money, but the actual possession of it in hand by the debtor. The debtor is not bound to count out the money if he has it and offers it.—The tender must be made without any condition that the creditor may with good reason object to. A demand of a receipt in full of all demands has often been held to invalidate a tender; not so much because a receipt was asked for, as because part was offered in full payment. And it seems that a debtor would lose the benefit of a tender if he should accompany it with a demand of a receipt for the sum that he pays, and because it was refused should retain the money. Tender of a larger sum than is due, with a request of the change or the balance, is not good; but a refusal of the money offered, for reasons distinct from the manner in which the offer is made, as for the insufficiency of the sum or the like, is a waiver of all objection to the form of the tender. The tender should be made in money made lawful by statute. A tender of good and current bank notes is good if no objection is made on the ground that they are not money. The effect of a tender will be destroyed if the creditor can show a subsequent demand by him of the proper fulfilment of the contract at the proper time, and a refusal by the debtor.—Tender does not bar a debt as payment would, but rather establishes the liability of the defendant; for, in general, he is liable to pay the sum which he tenders whenever he is required to do so. But the tender stops the recovery of damages or interest for delay in payment, and gives the defendant subsequent costs, provided the plaintiff recovers nothing beyond the sum tendered.—As in sales the property in chattels does not pass while any necessary act remains to be done, so if there be an obligation to deliver those articles, it may be said as a general rule that the obligation is not discharged by tender so long as anything is left undone which would prevent the property from passing under a sale. Chattels tendered, therefore, should be separated and distinguished from any others, and not be so mingled with others that are not to be delivered that they cannot be separately identified. The tender of goods may be made to an agent or by an agent, and must be equally unconditional as if of money; and if the agent of the deliverer has orders to deliver the chattels to the receiver only if he will cancel and deliver up the contract, this is not a tender, although the agent had the chattels at the proper time and place. Generally, if no time or place be specified, chattels are to be delivered where they were at the time of the contract, unless collateral circumstances designate a different place. If the time be fixed, but not the place, it will be presumed that the deliverer was to bring the articles to the receiver at that time; and for that purpose he must go with the chattels to the residence or place of business of the receiver, unless

something in their very nature or use, or some other circumstance of equivalent force, distinctly implies that they are to be left at some other place. And it may happen from the cumbrousness of the articles, or other circumstances, that it is obviously reasonable and just for the deliverer to ascertain from the receiver, long enough beforehand, where they shall be delivered; and then he will be held to this as a legal obligation. If the receiver refuses or neglects to appoint a place, or purposely avoids receiving notice of a place, the deliverer may appoint any place with a reasonable regard to the convenience of the other party, and there deliver the articles. If no expressions used by the parties and nothing in the nature of the goods or the circumstances of the case control the presumption, then the place where the promise is made is the place where it should be performed; and no action can be maintained upon such a promise unless the plaintiff can show a demand at the proper place and time, or a readiness to receive, and notice equivalent to a demand, or else that the demand would have been nugatory because the defendant could not have complied with it. If by the terms of the contract specific articles are to be delivered at a certain time and place in payment of an existing debt, this contract is fully discharged and the debt is paid by a complete and legal tender of the articles at the time and place, although the promisee was not there to receive them; and no action can be thereafter maintained on the contract. But the property in the goods has passed to the creditor, and he may retain them as his own, or take them elsewhere; or he may demand them, and if they are refused bring an action for them as his own.

**TENDON**, the fibrous cord or expansion by which a muscle is connected with the surface of bone. Tendons are composed of parallel bundles of white, inelastic, inextensible, fibrous tissue, the spaces between which are occupied by thin layers of loose areolar tissue, with a small proportion of elastic fibres, sufficient to allow a slight gliding motion of the different tendinous bundles upon each other. As a whole, however, the tendon is both inextensible and inelastic, and thus conveys at once the movement imparted by the muscular contraction to the bone into which it is inserted. The typical form of a tendon is that of a long, flexible, cylindrical cord, like those at the lower part of the forearm, for the flexion of the wrist and fingers. Others are more or less spread out into a ribbon-like form, like that of the sterno-mastoid muscle at the upper extremity of the sternum; while others are expanded into a broad and thin sheet or aponeurosis, like the tendinous expansions of the *latissimus dorsi*, or of the muscles on the anterior part of the abdomen. The long and cord-like tendons often run in narrow grooves of bone, in which they are confined by fibrous sheets passing over them from edge to edge. Their movement is sometimes facilitated by the existence of closed sacs or *bursæ*, situated between them and the bony surfaces over which they pass, and filled with a glairy lubricating fluid. Sometimes, as in the case of the tendon of the superior oblique muscle of the eyeball, they pass through a pulley-like loop or fibrous ring, and then return in an oblique direction to be inserted somewhere between the loop and their point of origin. Sometimes they have developed within them at certain points, where crossing articulations, small bones termed "sesamoid bones," the inner surface of which takes part in the formation of the joint. The patella, or knee pan, is regarded as an unusually large sesamoid bone, developed in the tendon of the great extensor muscle on the front part of the thigh.—Owing to their strong fibrous texture and inextensible quality, the tendons, when contracted or bound down by unnatural adhesions, are liable to produce or perpetuate deformities, particularly in the neck and the extremities. They require, under these circumstances, to be divided by a subcutaneous incision, releasing the contracted parts without bringing the air into contact with the wounded surface. This practice, known as "tenotomy," is largely resorted to in cases of wry neck, club foot, and many similar deformities.

**TENEDOS** (in earliest antiquity *Calydna*, *Leucophrys*, *Phœnice*, and *Lyrnessus*), a small island, about 10 m. in circumference, in the Grecian archipelago, now belonging to Turkey, 13 m. from the mouth of the Hellespont, and 4 m. W. of the coast of the Troad; pop. about 7,000, two thirds Greeks. The interior is fertile and well cultivated, producing corn, cotton, fruits, and excellent wine. The small town of Tenedos, on the E. coast, has a good port and is defended by two forts; the Greek quarter was almost entirely destroyed by fire in July, 1874.—In the legend of the Trojan war the island is mentioned as the place to which the Greeks withdrew their fleet, in order to make the Trojans think that they had departed, after leaving the wooden horse before Troy; and it was employed in the Persian war by Xerxes as a naval station. Subsequently, on several occasions, as in the Peloponnesian, Macedonian, and Mithridatic wars, it figured conspicuously as a stronghold; and in the middle ages the Turks and Venetians long contested its possession.

**TENERANI, Pietro**, an Italian sculptor, born at Torano, near Carrara, Nov. 11, 1789, died in Rome, Dec. 14, 1869. He studied after 1814 in Rome under Canova and Thorwaldsen, and became professor and finally president of the academy of St. Luke, and in 1860 chief director of museums. He excelled in religious and classical works, some of which are regarded as superior to the later productions of Canova, and became the head of a school distinguished for a careful elaboration of details and for graceful execution. His best known works include "Christ on the Cross," in silver, in St. Stephen's at Pisa; "The Descent from the

Cross," in the Torlonia chapel of St. John Lateran; the "Angel of the Last Judgment," in St. Mary's, Rome; "Flora," in possession of Queen Victoria; portrait busts of Thorwaldsen and Pius IX.; and many statues, including one of Bolivar. His last important work is the sarcophagus of Pius VIII. for St. Peter's.

**TENERIFFE** (Sp. *Tenerife*), one of the largest islands of the Canary group, about 150 m. N. W. of Cape Bojador, Africa. It is of triangular form, the N. and S. E. sides about 60 m. long, and the W. side 24 m.; area, about 800 sq. m.; pop. about 95,000. The coasts are steep, high, and broken by deep fissures; there are very few sand beaches, and no port accessible to large vessels which is secure in all weathers; but Santa Cruz, the capital of the island and of the Canaries (pop. about 11,000), has a good harbor. The island is volcanic. A lofty ridge traverses it centrally, and culminates near the W. side in the celebrated peak of Teneriffe or Teyde, 12,182 ft. above the sea. This consists of an enormous dome of trachyte covered with layers of basalt, rising from a plateau 7,500 ft. high. The peak itself rises about 2,350 ft. above the last narrow plain; its sides are very steep and difficult of ascent, and the summit is a narrow wall enclosing a crater about a mile in diameter with an average depth of 106 ft. The eruptions from this crater ceased long before the island was discovered by Europeans; but there have been recent eruptions from other craters, notably in 1704, '5, and '6, and 1798, the most recent. Hot vapors arise from the craters, and their surfaces are always warm. The next highest elevations are Chahora, 9,885 ft., 2½ m. S. W., and Azulejos, 9,400 ft., 3½ m. S. of Teyde. About one seventh of the island is fit for cultivation; the most fertile districts are at the E. end, the best being the plain of Laguna, about 12 sq. m. in extent, from which large crops of grain are obtained. The principal productions are cochineal, nuts, wine, and fruit; the first named is the only one of importance in commerce. In 1873 there was exported 2,476,433 lbs. of cochineal, valued at $1,225,289 in gold. The total value of all other exports during the same year was $295,060; of all imports, $1,988,045, including 3,390 tons of coal. The value of exports to the United States for the year ending Sept. 30, 1874, was $30,000. The commerce of the island is nearly all conducted through Santa Cruz. The only other important town is Laguna, in the plain of that name, with a fixed population of about 10,000, largely increased in the hot season. Orotava, on the N. coast, gives its name to a beautiful valley, formerly famous for its gigantic dragon tree, which was blown down by a hurricane at the beginning of 1868.

**TENIERS. I. David,** called the elder, a Flemish painter, born in Antwerp in 1582, died there in 1649. He was educated in the school of Rubens, subsequently studied in Italy, and after his return to Antwerp devoted himself exclusively to cabinet pictures. His favorite subjects were rural sports and merrymakings, alehouse interiors, chemists' laboratories, and grotesque subjects, such as the temptation of St. Anthony. He was greatly distinguished as a colorist, and his pictures commanded during his lifetime large prices. **II. David,** the younger, born in Antwerp in 1610, died in Brussels, Feb. 11, 1685. He early displayed a genius far superior to that of his father in the same specialty of painting, and found a patron in the Austrian archduke Leopold at Brussels, governor of the Spanish Netherlands, who appointed him gentleman of his bedchamber and his principal painter. The king of Spain appropriated a special gallery to his works, and he had hardly time to meet the fast increasing demand for them. He became director of the academy of Antwerp in 1644, but spent most of his life in the country near Mechlin, in order to familiarize himself with the life of the peasantry. His extraordinary facility in imitating the paintings in the archduke's gallery caused him to be called the Proteus of his art, and he was not less remarkable for his rapid, faithful, and elaborate execution. His charming delineations of the haunts and amusements of the toiling classes made him the most popular of all Flemish painters. He produced more than 1,000 pictures, including some of stupendous size. Among those best known are "The Village Wedding," "The Prodigal Son," "Heron Shooting," "The Bagpipe Player," and others in the Louvre, and "A Music Party," "Boors Regaling," "The Misers," and "Players at Trictrac," in the national gallery of London.

**TENNANT, William,** a Scottish poet, born at Easter Anstruther, Fifeshire, in 1785, died near Dollar, Feb. 15, 1848. He was educated at the university of St. Andrews. At an early age he lost the use of his feet, and in 1801 became clerk to his brother, a corn factor of Glasgow. Returning to Anstruther, he published in 1812 "Anster Fair," in the *ottava rima*, which passed through many editions. In 1813 he became parish schoolmaster of Dunino, and there mastered the Arabic, Syriac, and Persian languages. He afterward taught at Lasswade and at Dollar academy, and in 1835 was made professor of oriental languages in St. Mary's college, St. Andrews, and compiled Syriac and Chaldaic grammars. He published "The Thane of Fife" (1822); "Cardinal Beaton," a tragedy (1823); "John Balliol," a drama (1825); "The Dinging Down of the Cathedral" (of St. Andrews); "Hebrew Dramas founded on Bible History" (1845); and a "Life of Allan Ramsay" (New York, 1852).

**TENNEMANN, Wilhelm Gottlieb,** a German historian of philosophy, born at Brembach, near Erfurt, Dec. 7, 1761, died in Marburg, Sept. 30, 1819. Abandoning theology for philosophy, he completed his studies at Jena, and was professor there from 1798 to 1804, and subsequently at Marburg. After opposing the

Kantian system he became one of its first adherents. His most important work is the *Geschichte der Philosophie* (11 vols., Leipsic, 1798–1819), in which all systems are regarded from the standpoint of the critical school. An abridgment, *Grundriss der Geschichte der Philosophie* (Leipsic, 1812; 5th ed., 1828), has been translated into English by Arthur Johnson (Oxford, 1832; revised by J. D. Morell, London, 1852). His other works include *System der Platonischen Philosophie* (4 vols., Leipsic, 1792–'4), and translations into German from Locke, Hume, and De Gérando.

**TENNENT,** Sir **James Emerson,** a British author, born in Belfast, April 7, 1804, died in London, March 6, 1869. His name was originally Emerson, Tennent being added on the succession of his wife to the estate of her father, William Tennent. He graduated at Trinity college, Dublin, and was called to the bar at Lincoln's Inn in 1831, but never practised. Under the name of Emerson he published "Travels in Greece" (1825); "Letters from the Ægean" (2 vols., 1829); and "History of Modern Greece" (2 vols., 1830–'45). In 1832 he was elected to parliament for Belfast, and represented that city most of the time till 1845. From 1841 to 1845 he was secretary to the India board; in 1845 he was appointed civil secretary to the colonial government of Ceylon, and knighted. He returned in 1850, and in 1852 was member of parliament for Lisburn, and for a few months of that year secretary of the poor-law board. In November, 1852, he became one of the joint secretaries of the board of trade, and on his retirement in February, 1867, he was created a baronet. His works include "Belgium" (2 vols., 1841); "A Treatise on the Copyright of Designs for Printed Fabrics, &c." (1841); "Christianity in Ceylon, with an Historical Sketch of the Brahminical and Buddhist Superstitions" (1850); "Wine, its Use and Taxation" (1855); "Account of Ceylon" (2 vols., (1859; 5th ed., enlarged, 1860); "Sketches of the Natural History of Ceylon" (1861); "The Story of the Guns" (1864); and "The Wild Elephant, and the Mode of capturing and taming him in Ceylon" (1867).

**TENNESSEE,** one of the southern states of the American Union, the third admitted under the federal constitution, situated between lat. 35° and 36° 35′ N., and lon. 81° 37′ and 90° 15′ W.; greatest length from E. to W. 432 m., breadth 109 m.; area, 45,600 sq. m. according to the federal census, or 42,000 as reported by the state authorities. Its shape is rhomboidal, its E. and W. sides sloping at considerable, though not equal angles. It is bounded N. by Kentucky and Virginia, S. E. by North Carolina, S. by Georgia, Alabama, and Mississippi, and W. by Arkansas and Missouri, from which it is separated by the Mississippi river. The state is divided into 94 counties, viz.: Anderson, Bedford, Benton, Bledsoe, Blount, Bradley, Campbell, Cannon, Carroll, Carter, Cheatham, Claiborne, Clay, Cocke, Coffee, Crockett, Cumberland, Davidson, Decatur, De Kalb, Dickson, Dyer, Fayette, Fentress, Franklin, Gibson, Giles, Grainger, Greene, Grundy, Hamblen, Hamilton, Hancock, Hardin, Hawkins, Hardeman, Haywood, Henderson, Henry, Hickman, Houston, Humphreys, Jackson, James, Jefferson, Johnson, Knox, Lake, Lauderdale, Lawrence, Lewis, Lincoln, Loudon, McMinn, McNairy, Macon, Madison, Marion, Marshall, Maury, Meigs, Monroe, Montgomery, Moore, Morgan, Obion, Overton, Perry, Polk, Putnam, Rhea, Roane, Robertson, Rutherford, Scott, Sequatchie, Sevier, Shelby, Smith, Stewart, Sullivan, Sumner, Tipton, Trousdale, Unicoi, Union, Van Buren, Warren, Washington, Wayne, Weakley, White, Williamson, and Wilson. The chief cities and towns are: Nashville, the capital, which in 1870 had 25,865 inhabitants; Brownsville, 2,457; Chattanooga, 6,093; Clarksville, 3,200; Columbia, 2,550; Gallatin, 2,123; Jackson, 4,119; Knoxville, 8,682; Lebanon, 2,073; Memphis, 40,226;

State Seal of Tennessee.

Murfreesboro, 3,502; and Pulaski, 2,070. The population of the state and its rank in the Union at decennial periods, according to the federal census, have been as follows:

| YEARS. | Whites. | Slaves. | Free colored. | Aggregate. | Rank. |
|---|---|---|---|---|---|
| 1790.... | 31,913 | 3,417 | 361 | 35,691 | 17 |
| 1800.... | 91,709 | 13,584 | 309 | 105,602 | 15 |
| 1810.... | 215,875 | 44,535 | 1,317 | 261,727 | 10 |
| 1820.... | 339,927 | 80,107 | 2,737 | 422,771 | 9 |
| 1830.... | 535,746 | 141,603 | 4,555 | 681,904 | 7 |
| 1840.... | 640,627 | 183,059 | 5,524 | 829,210 | 5 |
| 1850.... | 756,836 | 239,459 | 6,422 | 1,002,717 | 5 |
| 1860.... | 826,722 | 275,719 | 7,300 | 1,109,801 | 10 |
| 1870.... | 936,119 | ....... | 322,331 | 1,258,520 | 9 |

Included in the aggregate of 1860 are 60 Indians, and 70 in that of 1870. Of the total population in 1870, 623,347 were males and 635,173 females; 1,239,204 were of native and 19,316 of foreign birth. Of the natives, 1,027,653 were born in the state, 20,217 in Alabama, 18,021 in Georgia, 19,867 in Kentucky, 15,451 in Mississippi, 51,110 in North Carolina, 4,420 in Ohio, 4,074 in Pennsylvania,

13,854 in South Carolina, and 43,387 in Virginia and West Virginia. Of the foreigners, 4,539 were born in Germany, 2,085 in England, and 8,048 in Ireland. The density of population according to the federal census was 27·6 persons to a square mile. There were 231,365 families, with an average of 5·44 persons to each, and 224,816 dwellings, with an average of 5·6 to each. The increase of population from 1860 to 1870 was 13·4 per cent. There were 429,592 persons from 5 to 18 years of age, 222,903 males from 18 to 45, and 259,016 male citizens 21 years old and upward. There were 290,549 persons 10 years of age and upward who could not read, and 364,697 unable to write; of the latter, 178,725 were white and 185,952 colored, 163,206 males and 201,473 females; 225,724 were 21 years old and over. The number of paupers supported during the year ending June 1, 1870, was 1,349, at a cost of $99,811. Of the 1,332 receiving support at that date, 314 were colored. The number of persons convicted of crime during the year was 722. Of the 981 in prison June 1, 1870, 560 were colored. The state contained 876 blind, 570 deaf and dumb, 925 insane, and 1,091 idiotic. Of the total population 10 years old and over (890,872), there were engaged in all occupations, 367,987; in agriculture, 267,020, of whom 136,925 were laborers and 129,550 farmers and planters; in professional and personal services, 54,396, including 1,256 clergymen, 24,563 domestic servants, 16,780 laborers not specified, 1,126 lawyers, 2,220 physicians and surgeons, and 2,250 teachers not specified; in trade and transportation, 17,510; in manufactures and mechanical and mining industries, 29,061. The total number of deaths from all causes was 14,239, being 1·13 per cent. of the entire population; from consumption, 2,377, there being 6 deaths from all causes to 1 from this disease; from pneumonia, 1,298, or 11 deaths from all causes to 1 from this disease. There were 652 deaths from croup, 571 from intermittent and remittent fevers, 729 from cerebro-spinal, enteric, and typhus fevers, and 750 from diarrhœa, dysentery, and enteritis.—The state presents eight great topographical divisions. On its E. border the Unaka, Smoky, Bald, and other mountains, belonging to the Appalachian chain, have an average elevation of 5,000 ft. above the sea, and an area (according to state measurements) of 2,000 sq. m. Between these mountains and the Cumberland table land on the west the valley of East Tennessee comprises a succession of ridges and minor valleys running in almost unbroken lines from N. E. to S. W. The average elevation of this valley is 1,000 ft., and its area 9,200 sq. m. The Cumberland table land rises about 1,000 ft. above the valley of East Tennessee, and has an area of 5,100 sq. m. Its E. side forms an almost continuous N. E. line, and presents an abrupt, rocky rampart. The W. edge is irregular and jagged, with deep coves and valleys. Next on the west, with an average elevation of 1,000 ft. above the sea, and an area of 9,300 sq. m., are the highlands, rim lands, or terrace lands, which extend to the Tennessee river. This division is for the most part a plain, traversed by numerous ravines and streams. In the centre of these highlands is the great central basin, elliptical and resembling the bed of a drained lake; its average depression is about 300 ft. below the highlands, and it has an area of 5,450 sq. m. This whole basin, with the surrounding highlands, is slightly inclined toward the northwest. The next natural division on the west is the western valley, or valley of the Tennessee, 10 or 12 m. wide, with an elevation of 350 ft. above the sea and an area of 1,200 sq. m. The surface is broken and irregular, various subordinate valleys extending from 20 to 25 m. into the highlands. The plateau or slope of West Tennessee, which constitutes the seventh grand division, is a great, gently undulating plain, which slopes toward the Mississippi. It has few rocks, is furrowed with river valleys, and extends westward for an average distance of about 84 m., when it abruptly terminates in a long and steep bluff or escarpment that overlooks the great alluvial bottoms of the Mississippi. It has an area of about 8,850 sq. m., with an average elevation of 500 ft. The extreme western natural division comprises the bottoms of the Mississippi, a low, flat, alluvial plain, having an area of 900 sq. m. and an average elevation of about 300 ft. It is covered with forests, and has numerous lakes and morasses. The state is also popularly divided into East, Middle, and West Tennessee; the first extending from the North Carolina border to about the middle of the Cumberland table land, the second from this line to the Tennessee river, and the third from the Tennessee to the Mississippi.—The rivers of Tennessee afford extensive commercial facilities and abundant water power. The most important are the Mississippi, which forms the W. border, and the Tennessee and the Cumberland, which with their tributaries drain more than three fourths of the state. The chief tributaries of the Mississippi are the Forked Deer and its branches (Obion river and South Forked Deer), the Big Hatchie, and Wolf river. The Forked Deer is navigable for steamboats to Dyersburg, and the Big Hatchie for several miles. (See Cumberland River, and Tennessee River.)—Geologically the state is divided into five districts or cross belts running from N. E. to S. W. The first, comprising the interval between the Mississippi and Tennessee rivers, is occupied (in an order from W. to E.) by the alluvial, tertiary, and cretaceous formations of the gulf of Mexico and the Atlantic seaboard. The second, from the Tennessee river to the W. foot of the Cumberland mountains, is a rolling country of nearly horizontal palæozoic rocks, with a great basin-like district of lower Silurian ground in the centre, watered by the Cumberland, Stone's, Duck, and

Elk rivers, and surrounded on all sides by subcarboniferous hills. The third is the mountain division of the coal; a plateau 2,000 ft. above the sea, 40 m. wide by 140 m. long, bounded E. by the valleys of the upper Tennessee and Holston rivers, and covered with a plate of carboniferous rocks, which is thinned and broken up into patches and mounds as it approaches the Alabama state line. The fourth district is the great valley of Knoxville or East Tennessee. It is a prolongation of the great valley of Virginia, the valley of the Shenandoah, and that of Harrisburg and Reading, Pa. Its rocks are mainly of Silurian age, upturned and broken by enormous faults, which bring them against the coal. On its E. side rise the Unaka mountains and their continuations, forming a fifth district, the true prolongation of the Blue Ridge and South mountain range, extending laterally into North Carolina, and composed of rocks of the lower periods of the Silurian age, the equivalents of the slate rock, gneiss, and marble of western Massachusetts and Vermont, and partly of "calciferous sand rock" age. The most abundant and valuable minerals of Tennessee are coal, iron, and copper. The state is crossed by the great Alleghany coal field, which extends from Pennsylvania to Alabama. In Tennessee it is nearly coextensive with the Cumberland table land, and forms an irregular quadrilateral 71 m. wide at the N. end and 50 m. at the S. It covers about 5,100 sq. m. The amount of coal has been estimated at 42,127,360,000 tons. The production of the state in 1870, according to the federal census, was 3,335,450 bushels, valued at $330,498. In 1874 there were 12 mines in operation, producing about 10,000,000 bushels annually. Iron exists in four distinct belts or areas. The eastern belt stretches across the E. part of the state, at the base of the border range of mountains, extending into Virginia on the northeast and Georgia on the southeast. The most abundant ore in this belt is the limonite, which occurs in Johnson, Sevier, Carter, and Blunt cos. There are also veins of magnetite and hematite ore, which will yield from 60 to 70 per cent. of metallic ores. There are five furnaces in this region, capable of producing about 15,000 tons annually; but owing to the lack of railroad facilities the amount produced does not exceed 10,000 tons. Iron ore containing oxide of manganese is abundant in Greene co., from which spiegeleisen is made. The dyestone belt skirts the E. base of the Cumberland table land, extending beyond the limits of the state on the northeast and southeast. In Tennessee it reaches from Chattanooga to Cumberland gap, about 150 m.; it spreads out laterally from 10 to 20 m. into the valley of East Tennessee, and includes the Sequatchie and Elk valleys. The chief ore of this belt is a stratified red iron rock, highly fossiliferous, occurring in layers, and called at many points dyestone, being sometimes used for dyeing. The ore is a variety of hematite, and yields from 50 to 60 per cent. of iron. There are four furnaces in this region. The Cumberland table-land belt of iron ore is coextensive with the coal field. The ore lies interstratified with shale, sandstone, and coal. It is called clay ironstone, and is an argillaceous carbonate of iron. It is inferior in quality, producing rarely more than 30 per cent., and usually not more than 20 per cent. of iron, and has not been worked. The western iron belt crosses the state N. and S., and lies mainly between the central basin and the Tennessee river, though extending in some counties a few miles W. of the river. It is about 50 m. wide, and embraces an area of about 5,400 sq. m. But the ore is found in available quantities only at certain points called "banks," some of which are miles in extent, while others occupy only a few acres. Some of these banks have been worked for 80 years with no signs of exhaustion. The ore is a limonite or brown hematite, some of it being inferior in quality; in other places the yield of iron is from 40 to 55 per cent. There are 11 furnaces in this region, with a monthly capacity of about 4,230 tons. Tennessee has decided advantages for making iron, in the abundance, cheapness, and contiguity of ore and of fuel; the disadvantages are distance from market and want of transportation facilities. Valuable deposits of copper are found in Polk co. in the S. E. corner of the state, covering an area of 40 sq. m. The ore is smelted by two extensive companies at Ducktown, having 25 furnaces and employing about 900 hands. From 1865 to 1874 the larger of these companies produced 8,476,872 lbs. of ingot copper. Tennessee is rich in marble, which is found in every part of the state, the varieties including black, gray, magnesian, fawn-colored, white, red, variegated, conglomerate, and breccia. Many quarries are worked. Limestone and other building stone abound in various parts of the state. Slate is common, but little of it is valuable. Several beds of millstone have been found, the most noteworthy being in Claiborne co. Hydraulic rocks abound in many counties, especially in Hardin, Wayne, Perry, Decatur, Warren, and Montgomery, and in Knox and McMinn cos. in East Tennessee. Lithographic stone of an excellent quality occurs in McMinn co. Granite of various shades of color, some of it rivalling the Scotch granite, is found in Carter co.; and unakite, a greenish compact granite, in the Unaka mountains, being peculiar to that locality. Deposits of potter's clay are found in East Tennessee, on the Knoxville and Ohio railroad, and in the vicinity of the lower Tennessee river, in the counties of Hickman, Henry, Perry, and Wayne; also in Montgomery and Houston cos. Some of this clay has been worked up into stone ware. There are numerous potteries, the largest being in Memphis, Nashville, and Knoxville. Kaolin is found in Carter co. Fire clay is found in Stewart and Houston cos.

and on the Cumberland river. It also exists in the coal measures immediately underlying a seam of coal. Lead occurs in various places in East and Middle Tennessee. Mines have been worked in Washington, Monroe, and Bradley cos.; one of the most promising is the Caldwell mine on Powell's river in Union co. This vein, which fills a nearly vertical fissure, about 20 in. wide, in nearly horizontal rocks, can be traced about a mile. The two ores of zinc, smithsonite and calamine, occur in considerable deposits in various localities, especially in Claiborne, Union, and Jefferson cos.; they are in greatest abundance in Union co. The Stiner belt, near Powell's river, is 50 or 60 ft. wide, and is marked by the absence of trees. The lead and zinc ores are often associated. Black oxide of manganese is found in small masses, associated with iron, all over the state. Iron pyrites also exists everywhere in the state; a large quantity is found associated with the copper at Ducktown. Large beds also occur near Greeneville in Greene co., and in Moore, Carter, and Perry cos. Heavy spar or baryta, used for cheap paints, is found in Middle and East Tennessee; it is mined in Greene, Washington, Jefferson, and some other counties. It is usually associated with lead, constituting the gangue of that mineral. Asbestus exists in large quantities in Cocke co. Copperas is abundant, and specimens of gypsum have been found. Salt was formerly made in the state, but its manufacture has been discontinued. Saltpetre abounds in numerous caves throughout Middle and East Tennessee. Petroleum has been found at various points, and 10,000 barrels of it has been obtained from the wells near Spring creek in Overton co.; but the production has not been found profitable. Extensive beds of lignite are found in many of the counties of West Tennessee. Alum occurs in the same situations as copperas in Middle Tennessee, Epsom salts in many of the saltpetre caves, and large quantities of bluestone (sulphate of copper) at Ducktown. The state collection of minerals in the capitol comprises, besides a great variety of specimens, 200 kinds of marble, of all colors from Parian white to jet black, all found in the state. Tennessee has marked advantages in the number, variety, excellence, and medicinal value of its mineral waters. Mineral springs occur upon the lofty peaks of the Unakas and along the bases of the long ridges of the eastern valley. The Cumberland table land abounds with sparkling chalybeate springs. There are also valuable sulphur and chalybeate springs in West Tennessee.—Tennessee has numerous caves, many of which were explored in 1811–'12 for the saltpetre earth in them, and a large amount of nitre was then manufactured from the earthy material thus obtained. In the Cumberland mountains are several caves which are 100 ft. or more below the surface and several miles in extent. One has been descended to a depth of 400 ft., where a stream of water was found having sufficient force and fall to drive a mill. Another, on the summit of Cumberland mountain, is perpendicular in its descent, and its depth has never yet been fathomed. Some of these caves contain fossils and bones of extinct species of animals; others, large deposits of the excrement of bats, valuable as a fertilizer. Big Bone cave when first explored contained bones of the mastodon. There are throughout the cavernous limestone region occasional "sink holes," as they are termed. These are hopper-shaped cavities on the surface which communicate with the caves and underground streams. Near Manchester, Coffee co., is an ancient work called the Stone Fort, enclosed by a rude stone embankment by tourists called a wall, upon which trees are growing, whose age is estimated at over 500 years. This mysterious enclosure lies in a peninsula formed by the near approach of two forks of Duck river, and occupies an area of 37 acres.—The climate is generally mild and remarkably salubrious, excepting in the swampy districts of West Tennessee. The eastern division is noted for its pure mountain air. The mean annual temperature along a line running E. and W. through the middle of the state is about 57° in the valley of East Tennessee, 58° in Middle, and 59° in West Tennessee. The temperature is about one degree higher along the southern, and about one degree lower along the northern boundary. Going from W. to E. there is a difference of elevation of more than 6,000 ft., which gives a wide range of climate and great variety in vegetable productions.—East Tennessee, excluding its great valley, has a limited surface adapted to cultivation. The soil of Middle Tennessee is generally good, producing large crops of wheat, rye, oats, Indian corn, buckwheat, barley, potatoes, hemp, hay, sweet potatoes, flax, cotton, and tobacco. The western division is almost level, and cotton, tobacco, and all kinds of grain are grown in extraordinary abundance. The soil of this part is a rich black mould. Along the banks of the Mississippi and Tennessee are extensive cane brakes, covered with reeds. The country is well watered. The N. W. part contains an extensive tract of swampy land. Nearly half of the state is wooded land, and presents almost every variety of timber found in the United States. West Tennessee is specially noted for the magnificence of its forests. The high mountains in the east are covered with forests of pine, which yield tar, pitch, turpentine, and lumber for export; white pine, chestnut, hemlock, and black walnut grow to immense size in the coves of the mountains. On the mountain slopes the sugar maple, ash, cedar, juniper, and savin are also abundant; and in the lower lands as well as in Middle Tennessee the poplar, hickory, black walnut, oak, beech, locust, and cherry are found. The most extensive red cedar forests in the United States are found in the central basin of Middle Tennessee. In the swamps and low lands of

West Tennessee the cypress, hackmatack, cottonwood, and swamp cedar occur in large quantities. Several wild or indigenous grasses grow spontaneously. The pawpaw, a low bushy tree or shrub, bearing a fruit somewhat resembling the banana, though inferior to it, is found in the river bottoms. The persimmon, which is common, yields a fruit which in sweetness and pleasantness of flavor equals the date. The black haw, red haw, wild plum, blackberry, wood grape, muscadine, strawberry, whortleberry, gooseberry, and service berry all grow wild and yield luxuriantly. Nuts of various kinds abound, as the walnut, hickory nut, hazel nut, chestnut, pecan, and chinquapin, all forming articles of export. Ginseng is found on all the elevated lands. The wild animals are the bear, found only in the mountainous districts, deer, raccoons, foxes, opossums, and squirrels. Horses, cattle, sheep, and swine are raised on a large scale, and many thousands are annually exported. The hills and mountain slopes afford an abundance of fine pasturage. Much attention is given to wool growing.—According to the federal census of 1870, the state contained in farms 6,843,278 acres of improved land, 10,771,396 of woodland, and 1,966,540 of other unimproved land. The total number of farms was 118,141, containing an average of 166 acres each; 18,806 contained from 100 to 500 acres, 412 from 500 to 1,000, and 50 over 1,000. The cash value of farms was $218,743,747, of farming implements and machinery $8,199,487. The staple crops of 1873 were reported as follows by the United States department of agriculture:

| CROPS. | Bushels. | Yield per acre. | Acres. | Total value. |
|---|---|---|---|---|
| Indian corn.... | 42,604,000 | 22·5 | 1,893,511 | $24,710,320 |
| Wheat......... | 7,414,000 | 7·2 | 1,029,722 | 9,860,620 |
| Rye........... | 204,000 | 9 | 22,667 | 183,600 |
| Oats........... | 5,613,000 | 20·6 | 272,476 | 2,301.330 |
| Barley......... | 83,000 | 19·2 | 4,323 | 70,550 |
| Buckwheat.... | 74,000 | 10·5 | 7,047 | 70,300 |
| Potatoes....... | 1,009,000 | 75 | 13,453 | 665,940 |
| Tobacco (lbs.).. | 23,750,000 | 675 | 35,185 | 1,425,000 |
| Hay (tons)..... | 134,500 | 1·25 | 107,600 | 2,084,750 |

The total value of these crops was $41,372,410; whole number of acres, 3,385,984. The number and value of domestic animals in 1874 were reported as follows:

| ANIMALS. | Number. | Average price. | Total value. |
|---|---|---|---|
| Horses.................... | 302,900 | $77 51 | $23,477,779 |
| Mules..................... | 103,200 | 90 84 | 9,374,688 |
| Oxen and other cattle..... | 355,100 | 14 22 | 5,049,522 |
| Milch cows... ........... | 247,700 | 21 86 | 5,414,722 |
| Sheep..................... | 350,000 | 2 09 | 731,500 |
| Swine..................... | 1,420,900 | 3 09 | 4,390,581 |

Peanuts, constituting an important crop, are raised in the counties of Perry, Hickman, and Humphreys, and parts of Dickson and Lewis, all of which are on the W. side of the Highland rim. The production amounted to 680,000 bushels in 1872, 110,000 in 1873, 200,000 in 1874, and 250,000 in 1875. The average yield is about 40 bushels an acre. The shipment of cotton from Tennessee amounted to 378,813 bales in 1872–'3, 489,534 in 1873–'4, and 446,674 in 1874–'5, most of which was the product of the state. In 1873 there were 613,267 acres planted with cotton. The best grows in the S. half of West Tennessee; it is grown in the whole of the central basin S. of Nashville. As a tobacco-growing state Tennessee ranks third, Kentucky being first and Virginia second. The annual product of the state varies from 20,000,000 to 25,000,000 lbs., or from 13,000 to 22,000 hogsheads. The average yield per acre is between 700 and 800 lbs., though as much as 1,800 lbs. can be produced upon the best soils in good seasons. The soil and climate are well adapted to the cultivation of grapes; much attention has recently been given to this industry, and also to the production of honey.—The total number of manufacturing establishments, according to the census of 1870, was 5,317, using 732 steam engines of 18,467 horse power and 1,340 water wheels of 19,514 horse power, and employing 19,412 hands, of whom 17,663 were males above 16 years of age, 1,089 females above 15, and 660 youth. The amount of capital invested was $15,595,295; wages, $5,390,630; materials, $19,657,027; products, $34,362,636. The statistics of the most important industries were reported as follows:

| INDUSTRIES. | No. of establishments. | No. of hands employed. | Capital. | Value of products. |
|---|---|---|---|---|
| Agricultural implements... | 25 | 110 | $62.900 | $182.772 |
| Blacksmithing ............ | 719 | 1,445 | 230,897 | 873,888 |
| Boots and shoes........... | 309 | 707 | 181.601 | 665,522 |
| Carpentering and building. | 333 | 847 | 250,595 | 1.149,598 |

| Wooden ware............. | 4 | 72 | 40.510 | 139,100 |
| Wool-carding and cloth-dressing................ | 133 | 265 | 185.798 | 491,847 |
| Woollen goods......... .. | 15 | 163 | 188,075 | 204.997 |

There has been a marked progress in many industries since 1870, especially in the manufacture of cotton, iron, liquors, and carriages and wagons. In 1875 there were 40 cotton mills with 55,384 spindles; cotton consumed during the year, 6,701,718 lbs., or 14,443 bales. There are no United States customs districts in Tennessee, but Memphis and Nashville are ports of delivery in the district of Louisiana. At the close of 1875 there were 27 national banks in operation, with a capital stock of $3,455,300 and a circulation of $2,474,323.—Tennessee had 466 m. of railroad in 1855, 1,253 in 1860, 1,296 in 1865, 1,492 in 1870, and 1,641 in 1875. The lines lying wholly or partly in the state in 1875 were as follows:

| NAMES OF CORPORATIONS. | TERMINI. | | Miles completed in the state in 1875. | Total length between termini when different from preceding. |
|---|---|---|---|---|
| | FROM | TO | | |
| East Tennessee, Virginia, and Georgia | Bristol | Dalton, Ga | 225 | 240 |
| | Cleveland | Chattanooga | 30 | .... |
| Owned.. Cincinnati, Cumberland Gap, and Charleston | Morristown | Wolf Creek | 39 | .... |
| Owned.. Knoxville and Ohio | Knoxville | Careyville | 38 | .... |
| Owned.. Rogersville and Jefferson | Junction E. S. V. and G. | Rogersville | 15 | .... |
| Knoxville and Charleston | Knoxville | Maryville | 16 | .... |
| Louisville, Nashville, and Great Southern | Louisville, Ky | Nashville | 46 | 185 |
| Memphis division | Memphis Junction, Ky | Memphis | 214 | 260 |
| Leased, Nashville and Decatur | Nashville | Decatur, Ala | 94 | 123 |

—The governor is elected for two years, and receives an annual salary of $4,000. He must be 30 years of age and a citizen of the state for seven years next preceding his election. He is not eligible for more than six years in any period of eight. In case of the removal of the governor from office, or of his death or resignation, the executive functions devolve upon the speaker elected by the senate. The secretary of state is elected for four years by joint vote of the general assembly, and receives a salary of $1,800 a year and perquisites. A bill may be passed over the executive veto by a majority vote of each house. The state treasurer and comptroller are appointed by the general assembly for two years. The constitution provides that the number of representatives in the legislature shall not exceed 75 until the population of the state shall be 1,500,000, and shall never exceed 99. The number of senators is limited to one third of the number of representatives. There are now (1876) 25 senators and 75 representatives. The sessions of the legislature are biennial, beginning on the first Monday of January in odd years. Senators and representatives receive $4 a day and $4 for every 25 miles travel to and from the capital. No member will be paid for more than 75 days of a regular session, or for more than 20 days of an extra session, or for any days when absent from his seat. The judicial power is vested in a supreme court and chancery, circuit, county, and justices' courts. The supreme court consists of a chief justice and five associates, who are elected by the people for eight years, and receive a salary of $4,000 each. Its jurisdiction is appellate only. Terms are held annually in Knoxville, Nashville, and Jackson. The attorney general and reporter for the state is appointed by the judges of the supreme court. Judges of the circuit and chancery courts are elected by the people for eight years. Two terms of the chancery court are held in each county annually. They have all the powers and jurisdiction incident to a court of equity, and exclusive jurisdiction of all equity cases where the amount in controversy exceeds $50. They have jurisdiction with the county courts over the person and property of persons of unsound mind, and of infants. Three terms of the circuit court are annually held in each county. Concurrently with justices of the peace they have jurisdiction of all debts and demands on contract over $50, and exclusive jurisdiction of matters relating to the validity of wills; also appellate jurisdiction of all suits brought before inferior tribunals. Each county has a court consisting of the justices of the county, which has jurisdiction of probate matters. Justices of the peace are elected by the people for six years, and constables for two years. Judges may be removed from office by a two-thirds vote of the legislature. They are prohibited from charging juries with respect to matters of fact, but may state the testimony and declare the law. Fines exceeding $50 on any citizen must be assessed by a jury. The right

of suffrage is given to every male person of the age of 21 years who is a citizen of the United States and a resident of Tennessee for one year, and of the county where he offers to vote for six months. There is no other qualification except the payment of a poll tax of not less than 50 cents nor more than $1 a year. In 1867 the state gave to negroes the right to vote. Elections for governor and members of the general assembly are held biennially in even years, on the first Tuesday after the first Monday in November; for judicial and other civil officers, on the first Thursday in August. Ministers of the gospel and priests are ineligible as members of the legislature. No person who denies the being of God or a future state of rewards and punishments can hold any civil office. Any person who has engaged in a duel or preparations for a duel, either as principal or second, is disqualified from holding any office of honor or profit, besides being subject to punishment by law. Amendments to the constitution may be proposed in either branch of the general assembly; before taking effect they must be approved by a majority of the members elected to each house of the general assembly when first proposed, by two thirds of the next legislature, and subsequently by a popular vote. The grounds of divorce are: impotence, adultery, desertion for two years, conviction of an infamous crime or of felony, malicious attempt upon the life of the wife, pregnancy by another man at the time of marriage without the husband's knowledge, cruelty, indignities by the husband forcing the wife to separation, abandonment of the wife or turning her out of doors, and refusal to provide for her. The legal rate of interest is 6 per cent., but any rate not exceeding 10 per cent. may be contracted for in writing; if more than 10 per cent. is agreed upon, only 6 per cent. can be collected. Usury is punishable by a fine of not less than $100. Tennessee is represented in congress by 10 representatives and 2 senators, and has therefore 12 votes in the electoral college.—On Dec. 19, 1874, the bonded debt of the state was $22,908,400, which was largely contracted by the indorsement of railroad bonds. The assets of the state on bond account amounted to $3,817,896. The state revenue during 1873 and 1874, not including bonds or coupons paid by railroad companies, amounted to $3,618,703, and the disbursements to $3,290,158. According to the federal census, the true value of property was $201,246,686 in 1850, $493,903,892 in 1860, and $498,237,724 in 1870. The assessed value of all taxable property, as reported by the state authorities, was $308,089,738 in 1873 and $289,533,656 in 1874. The amount of state tax levied in 1873 was: East Tennessee, $254,200; Middle, $542,686; West, $435,472; total, $1,232,358. In 1874 it was: East Tennessee, $192,913; Middle, $401,563; West, $410,190; total, $1,005,066. The total valuation of taxable property in 1872 was $265,874,258; taxation, $1,090,694. The constitution provides that all property shall be taxed according to its value, so that the taxes shall be equal and uniform throughout the state, and that no species of property shall be taxed higher than any other of the same value. But the legislature is empowered to except from taxation property held by the state, counties, cities, or towns, and used exclusively for public or corporation purposes, and such as may be held and used for purposes purely religious, charitable, scientific, literary, or educational. In 1875 the comptroller reported that no railroad company had ever paid any taxes to the state; and that no corporations, excepting insurance companies and a few banks, had paid the taxes levied by law.—The state prison is in Nashville, and there are also several temporary prisons in various parts of the state, where convicts are employed upon railroads, mines, &c. The total number in confinement during the two years ending Dec. 1, 1874, was 1,625, of whom 744 were held on Dec. 1, 1872; 881 were received during that period, and 963 were in confinement at the end. Of the last number, 380 were white and 583 colored; 925 were males and 38 females; 13 had a good and 97 a fair education, 199 could read and write, and 654 had no education; 34 were under 16 years of age, and 275 under 21; 21 were sentenced for life, and 69 for 20 years or longer. The prisoners are employed under lease on public works, buildings, railroads, &c. The revenue thus received is reported to be greater than the cost of supporting the prison. There is preaching and Sunday school instruction. The state hospital for the insane, near Nashville, was opened in 1852. The average daily number of patients during the two years ending with 1874 was 379; the whole number under treatment during that period was 561, of whom 374 remained on Jan. 1, 1875. Of the latter, all but 37 were maintained free of charge. The cost of maintaining the institution during the two years named was $157,987. The accommodations of the hospital are inadequate, the number of insane in the state being estimated at not less than 1,200. The Tennessee school for the blind, in Nashville, opened in 1844, had 55 pupils in 1874. Its cost during that year was $33,890. It is estimated that there are not fewer than 1,200 blind in the state. This school has recently been very much enlarged. The Tennessee deaf and dumb school is in Knoxville, and was opened in 1845. The number of pupils in attendance during the two years ending with 1874 was 155, of whom 121 remained on Jan. 1, 1875. There were seven instructors. The ordinary expenditures during this period amounted to $53,356.—There was no satisfactory system of common schools in Tennessee prior to 1873, when the present law providing for a general state system was enacted. The school fund, which had been lost or diverted to other purposes, was restored, together with the suspended interest. A per-

manent fund, amounting in 1875 to $2,512,-500, was thus secured; the interest on this, at the rate of 6 per cent. per annum, is distributed semi-annually among the counties according to school population. The law also authorizes for school purposes a poll tax of $1, and a tax of one mill on the dollar upon all the taxable property of the state, and provides that when the money derived from the school fund and the taxes imposed by the state shall be insufficient to support a public school for five months in the year in each of the districts in any county, the county court shall levy an additional tax for the purpose, or submit the proposition to a vote of the people. About one half of the counties of the state have levied an additional tax to prolong the schools. The total annual income from the permanent fund and state taxation is about $600,000. The state superintendent of public instruction is appointed for two years, and receives an annual salary of $3,000. County superintendents are elected biennially by the county courts. Three directors are elected in each district for three years. The public schools are free to all persons between the ages of 6 and 18 years; but there must be separate schools for colored persons. The school population (one county not reporting) on June 30, 1875, was 425,901; white, 319,671; colored, 106,230. The number of pupils enrolled (one county not reporting) was 198,085; average attendance (16 counties not reporting), 136,118; number of schools (13 counties not reporting), 3,942; school revenue, $740,316; total expenditures, $703,358. In 1873-'4 public schools in various parts of the state received aid from the Peabody education fund to the extent of $34,300. The state normal university, under the control of the state board of education, was opened as a department of the university of Nashville in December, 1875. It has an annual revenue of $6,000 from the Peabody education fund and $6,000 from the university of Nashville. Normal instruction is also afforded in several of the colleges. In several of the cities there are efficient systems of free schools, supported in part by the cities and in part from the state and county school revenues. The universities and colleges of Tennessee, with the number of instructors and pupils in 1874-'5, were as follows:

| NAME OF INSTITUTION. | When opened. | Where situated. | Denomination. | No. of instructors. | No. of pupils in collegiate department. | No. of pupils in all departments. |
|---|---|---|---|---|---|---|
| Beech Grove college | 1868 | Beech Grove | None | 4 | 23 | 135 |
| Central Tennessee college | 1866 | Nashville | Methodist Episcopal | 9 | 2 | 240 |
| Christian Brothers' college | 1871 | Memphis | Roman Catholic | 9 | 48 | 127 |

| Vanderbilt university | 1875 | Nashville | Methodist Episcopal, South | 27 | 140 | 300 |

The East Tennessee university embraces the state college of agriculture and the mechanical arts, for which provision was made by congress in 1862. The university was organized in 1840 (the East Tennessee college having been opened in 1808), and the agricultural college in 1869. There are three courses of study of four years each, agricultural, mechanical, and classical; and two preparatory courses of three years each. Each senator is entitled to name two, and each representative three students, who may attend the institution without charge for tuition, and may also pass free on railroads between their homes and the university. For others, the annual cost of tuition is $36 in the college and $30 in the preparatory department. Students are required to perform manual labor during the freshman and sophomore years. The university has a considerable library, and cabinets of geology, mineralogy, and zoölogy. The university of the South, at Sewanee, is under the control of the Protestant Episcopal church. It has separate schools for each department of learning. The institution has about 10,000 acres of land on a plateau of the Cumberland mountains, 2,000 ft. above the sea and 1,000 ft. above the surrounding country. Owing to the favorable climate of this elevation, studies are continued during the summer, and a long vacation occurs in the winter. The university has a library of over 5,000 volumes. The East Tennessee Wesleyan university, at Athens, has a collegiate department, with classical and scientific courses, and preparatory and academic departments. Fisk university was organized in 1866 through the efforts of the American missionary association of New York. It is designed for the instruction of colored persons, and has made the training of teachers a prominent part of its work. It was named after Gen. C. B. Fisk, then commissioner of the freedmen's bureau, through whose efforts government buildings were obtained for the institution. Since 1871 upward

of $100,000 have been raised for it by concerts given in the north and in Great Britain by the "Jubilee Singers." With this money 25 acres of land have been purchased, on which has been erected Jubilee hall, 128 by 145 ft. and six stories high. For the university of Nashville and Central Tennessee college, see Nashville; for Cumberland university, see Lebanon; see also Vanderbilt University. Instruction in theology is provided by Central Tennessee college; in law, theology, and medicine, by Cumberland and Vanderbilt universities; and in medicine and surgery, by the university of Nashville and the Tennessee college of pharmacy in Nashville. The last named was organized in 1872, and in 1875–'6 had seven instructors. In 1870 the state contained 3,505 libraries with an aggregate of 802,112 volumes. Of these, 2,732 with 597,399 volumes were private, and 773 with 204,713 other than private, including the state library of 19,000 volumes. The total number of newspapers and periodicals in 1875 was 141, including 9 daily, 1 tri-weekly, 1 semi-weekly, 110 weekly, 1 bi-weekly, 1 semi-monthly, 17 monthly, and 1 quarterly. In 1870 there were 3,180 religious organizations, having 2,842 edifices with 878,524 sittings, and property valued at $4,697,675, divided as follows:

| DENOMINATIONS. | Organizations. | Edifices. | Sittings. | Property. |
|---|---|---|---|---|
| Baptist, regular | 942 | 877 | 245,151 | $843,675 |

—The name of Tennessee is derived from Tannassee, the Indian name of the Little Tennessee river. De Soto probably visited the spot where Memphis now stands. The first settlement was attempted in 1754 by a small body of North Carolinians, but they were speedily driven from the country by the Indians. In 1756 the first permanent settlement was made, and Fort Loudon built on the Tennessee river about 30 m. from the present site of Knoxville. This was the first Anglo-American settlement W. of the Alleghanies and S. of Pennsylvania. In 1760 the fort was besieged by the Indians, and the whites capitulated, stipulating that they should be allowed to return to North Carolina. On the second day of their march they were overtaken by the savages and many of them butchered, and the survivors reduced to captivity. In 1761 another armed force from Virginia and North Carolina entered the district, and after a number of successful battles with the Indians compelled them to sue for peace. A treaty was made with them, and the settlements along the Watauga and Holston rivers increased rapidly, being known from 1769 to 1777 as the Watauga association. In the colonial assembly of North Carolina in 1776 the territory was represented by deputies as the district of Washington; and in the revolutionary war the settlers flocked to the standard of the colonists. At the close of the revolution a settlement was made on the Cumberland river where Nashville now stands. From 1777 to 1784 the territory formed part of North Carolina, which set apart a portion of the district in the vicinity of Nashville for bounty lands for her revolutionary soldiers. In 1785 the people became dissatisfied with the manner in which they were treated by the government of that state, and organized the state of Franklin, which was maintained until 1788, when it was again united with North Carolina. In 1789 that state ceded the territory to the general government, and in 1790 it was organized, together with Kentucky, as the territory of the United States south of the Ohio. In 1794 a distinct territorial government was granted to Tennessee; and in 1796 a state constitution was formed at Knoxville, and Tennessee was admitted into the Union. The constitution was amended in 1834–'5, and again in 1853. The seat of government was at Knoxville from 1794 to 1811, excepting in 1807, when it was at Kingston; from 1812 to 1815 at Nashville; in 1817 at Knoxville; in 1816 and from 1819 to 1825 at Murfreesboro; and from 1826 to the present time it has been at Nashville. The general assembly of Tennessee was convoked in extra session Jan. 7, 1861, to consider what action should be taken by the state in view of the impending difficulties between the north and the south. In East Tennessee the people were generally opposed to secession; in West Tennessee there was a strong popular sentiment in favor of separation. The governor, Isham G. Harris, actively favored the southern cause. On Feb. 9 the people of the state voted on the question whether a convention should be held to consider the subject of withdrawing from the Union, and also for delegates to the convention. In a total vote of 127,000, there was a majority of nearly 12,000 against a convention. Of those who voted for delegates a majority of about 64,000 were in favor of the Union. The requisition for troops made upon Tennessee by the president after the firing upon Fort Sumter was refused by Gov. Harris, who again summoned the legislature to meet in extra session. Early in May a military league was formed with the Confederate States by commissioners appointed for that purpose, and was ratified by the legislature. On May 6 the legislature again provided for submitting the question of secession to the people. The election was held on June 8, and resulted in a majority of 57,675 for separation, the total vote being 152,151. In East Tennessee there was a large majority in favor

of the Union. Troops were now recruited and armed by the state for the confederate army and to resist invasion from the north. Batteries were erected to command the Mississippi from Memphis to the Kentucky line; troops were concentrated in West Tennessee under Gen. Pillow; and the confederate forces took possession of the three gaps in the mountains of East Tennessee. The invasion of Tennessee by the federal forces was begun early in 1862 by a combined naval and military expedition, which captured Forts Henry and Donelson in February. (See FORT DONELSON.) Nashville, the headquarters of the confederate general A. S. Johnston, was taken a few days afterward, when the state government was removed to Memphis. (See NASHVILLE.) A large portion of the state having now been restored to federal authority, Andrew Johnson was appointed military governor by President Lincoln, and assumed the duties of the office in Nashville on March 12. In the same month a formidable fleet of gunboats left Cairo, Ill., for the purpose of regaining the Mississippi river from confederate control. The advance of this fleet forced the confederates to abandon Island No. 10, Forts Pillow and Randolph, and other strongholds; and on June 6 Memphis was taken by the federal forces after a severe engagement between the gunboats. In November Gen. Rosecrans advanced from Nashville upon Murfreesboro, which was the centre of Gen. Bragg's operations in Tennessee. After a severe engagement lasting several days, the place was abandoned by the confederates, Jan. 4, 1863, and then became the depot of supplies for Gen. Rosecrans's army. The confederates now fell back to Shelbyville, and on the advance of Rosecrans in June retired to Chattanooga, which they abandoned on Sept. 8 upon the approach of Rosecrans. On the 19th and 20th a severe battle was fought about 12 m. S. W. of Chattanooga. (See CHICKAMAUGA.) The Union forces were repulsed, but continued to occupy Chattanooga, which however was besieged by the confederates. In the latter part of November an advance was made upon the confederate lines by Gen. Grant, which resulted in the complete rout of the confederates. In this engagement were fought the battles of Lookout mountain and Missionary ridge. (See CHATTANOOGA.) In the mean time Gen. Burnside had marched into East Tennessee, and he took peaceable possession of Knoxville early in September. In November, 1864, the state was invaded by a confederate force under Gen. Hood. Battles were fought with the federal forces at Franklin and at Nashville, the latter resulting in the complete rout of the confederates, under Gen. Hood, and their retreat from the state. (See NASHVILLE.) During 1864 numerous raids were made in different parts of Tennessee by the confederates. On Jan. 9, 1865, a state convention assembled in Nashville and proposed amendments to the constitution, abolishing slavery and prohibiting the legislature from recognizing property in man. A schedule was adopted annulling the military league made in 1861 with the Confederate States, also the declaration of independence, the ordinance of secession, and all acts of the confederate state government, and prohibiting the payment of any debts contracted by that government. These amendments were ratified by the people on Feb. 22. W. G. Brownlow was subsequently chosen governor, and members of the legislature were elected. Each voter at these elections was required to take an oath that he had been and would continue to be loyal to the United States. The legislature met in Nashville early in April, ratified the 13th amendment to the federal constitution, reorganized the state government, and elected senators to congress. Among the acts passed was one prescribing the qualifications of voters, which disfranchised those who had not been "publicly known to have entertained unconditional Union sentiments from the outbreak of the rebellion until the present time." The 14th amendment to the federal constitution was ratified in 1866, and the state was soon after admitted to representation in congress. The revision of the constitution by a convention sitting at Nashville from Jan. 10 to Feb. 22, 1870, was ratified on March 26 by a popular vote of 98,128 to 33,872.—See "The Geology of Tennessee," by Dr. J. M. Safford (1869), and "The Resources of Tennessee," prepared under the direction of the state board of agriculture by J. B. Killebrew (Nashville, 1874).

**TENNESSEE RIVER**, the largest tributary of the Ohio, formed by the union of the Clinch and Holston rivers, which rise in S. W. Virginia, and unite near Kingston, Roane co., Tenn. At first the course of the Tennessee is S. W. to Chattanooga, near the S. line of the state, where it passes through a part of the Cumberland range of mountains in a series of bends, and again turns S. W., entering the state of Alabama, and at Gunter's Landing, Marshall co., Ala., assumes a direction nearly W. by N. Between Lauderdale and Lawrence counties it spreads in a broad but shallow expansion called Muscle shoals, flowing over flint and limestone rocks in a succession of rapids for 36 m., and affording a large amount of water power. It afterward passes near Tuscumbia and Florence, on opposite sides, and at Chickasaw on the Mississippi line turns N. W., and forms the boundary thence to the Tennessee line between Alabama and Mississippi. Reëntering Tennessee, after a circuit of nearly 300 m. in Alabama, it flows almost due N. till it reaches Birmingham, Ky., when it turns W. N. W. and enters the Ohio at Paducah, McCracken co., 50 m. from the mouth of the latter. Its length from Kingston to Paducah is estimated at 800 m., but from the source of its longest affluent, the Holston, it is more than 1,100 m. Its principal tributaries are the Sequatchie,

Paint Rock, Flint, and Duck rivers, and Elk and Shoal creeks, entering it from the right; and the Hiawassee, Big Sandy, and Clark's rivers, and Town and Big Bear creeks, from the left. The fall of the river in its whole course is computed at about 2,000 ft. It is navigable from the Muscle shoals to the Ohio, 259 m.; above the shoals steamboats ascend to Knoxville, nearly 500 m. The scenery on the upper portion of the river is very beautiful. Darby estimates the area drained by the Tennessee and its tributaries at 41,000 sq. m.

**TENNIEL, John.** See p. 908.

**TENNIS,** a game of ball, played in a court built for the purpose, with a playing floor 112 by 40 ft., end walls 30 ft. high, side walls 20 ft. high, and usually lighted by skylights or windows above the 20-foot line. The players are two or four persons divided as partners on the "service" side and the "hazard" side. The ball is struck with a bat, called a racket, the striking part of which is covered with a close hard network of tendon. The player or party in strikes a ball, or "serves" it, against the head wall of the court. This ball must come to the ground over "the line," which is a network stretched across the middle of the court, 5 ft. high at each end and 3 ft. high in the middle. It is returned by the player or party out, who must in turn deliver it, by its rebound, at a certain place in the court, when it is again struck by the player in; and so the game continues. Whoever fails to "put the ball up" properly on the head wall, or to deliver it at the proper place on the court, loses. If it is the player in that fails, he loses his hand and goes out; if it is the player already out, his adversary scores a stroke toward game. There are several other contingencies which go to making the score, and the numerous angles caused by the walls constitute the intricacies of the game.—The name is from the French *tenez*, hold, as in striking the ball the racket must be held firmly. The game originated in France in the 15th century, and Louis XI., Henry II., and Charles IX. were expert players. M. Barre, who died in 1873, for many years superintendent of the tennis court in the Tuileries, was considered the best player that ever lived. The oldest English tennis court was built early in the 16th century in Hampton Court palace. There are two or three club courts in London, one at Leamington, and one at Brighton.

**TENNYSON, Alfred,** an English poet, born at Somersby, Lincolnshire, in 1809. His father was the Rev. George Clayton Tennyson, rector of Somersby and vicar of Bennington and Grimsby. His mother was a daughter of the Rev. Stephen Fytche, vicar of Louth. Alfred is the third of twelve children. He received his early education from his father, and was sent to Trinity college, Cambridge, where in 1829 he gained the chancellor's medal for a poem in blank verse entitled "Timbuctoo." In 1827, with his brother Charles (who has since become vicar of Grasby and assumed the name of Turner), he had published a small volume entitled "Poems, by Two Brothers." Coleridge expressed the opinion that only the pieces signed "C. T." gave promise of a coming poet. In 1830 Alfred published "Poems, chiefly Lyrical," in which the only striking piece was "Mariana;" but a revised and enlarged edition (1833) contained "The Lady of Shalott," "The May Queen," "Œnone," "A Dream of Fair Women," and "The Lotos-Eaters." This volume attracted comparatively little attention. In 1842 he published "English Idyls, and other Poems" (2 vols.), which contained all that he cared to preserve of the previous volume, and included also "Locksley Hall," "Morte d'Arthur," "The Talking Oak," "The Day-Dream," "The Two Voices," "St. Simeon Stylites," and "Ulysses." Tennyson's acknowledged rank as the first of living poets dates from the publication of these volumes. In 1847 he published "The Princess, a Medley," in blank verse, which has for its theme the question of the proper sphere of woman. The songs that form the interludes were introduced in the second edition. "In Memoriam," a series of 129 brief elegiac poems, suggested by the death of his friend Arthur Henry Hallam (see HALLAM), and written at intervals since 1833, appeared anonymously in 1850. On Nov. 21, 1850, after the death of Wordsworth, Tennyson was appointed poet laureate. His only notable performances in that capacity are the "Ode on the Death of the Duke of Wellington" and the "Charge of the Light Brigade at Balaklava," the popularity of each of which has been inversely as its merits. Both of these were included in the volume entitled "Maud, and other Poems" (1855). "Maud" was so anomalous, both in narrative treatment and metrical construction, that critics and readers were widely at variance concerning it; but there was no dissent from the applause which greeted the "Idyls of the King" (1859), four stories in blank verse, under the titles "Enid," "Vivien," "Elaine," and "Guinevere," drawn from the legends of King Arthur. These began a series which was continued in "The Holy Grail," "Gareth and Lynette," "Pelleas and Etarre," "The Last Tournament," and "The Passing of Arthur" (1869–'72). The whole epic had been foreshadowed in the prelude to the fragment entitled "Morte d'Arthur," which after 30 years found its place in the closing poem of the series. "Enoch Arden, and other Poems" (1864), included "Sea Dreams, an Idyl," for which Tennyson had received £10 a line on its original publication in "Macmillan's Magazine." With the exception of "Tithonus," "The Northern Farmer" (in dialect), and one or two other short pieces, the volume contained nothing worthy of the laureate; but the principal poem met with a wide popularity, and its title has become proverbial, from the supposed peculiarity of its

plot. "The Window, or the Songs of the Wrens," written for music by Arthur Sullivan, appeared in 1870, and "Queen Mary, a Drama," in 1875. Tennyson lived at various places, much of the time in London, till 1851, when he married Emily, daughter of Henry Sellwood, and settled at Farringford, Freshwater, Isle of Wight. In 1869 he removed to Petersfield, Hampshire. He has also a residence at Aldworth, Haslemere, Surrey, and is lord of the manors of Grasby and Prior's Freshwater. The university of Oxford conferred on him the degree of D. C. L. in 1859. Since 1850 his poems have been regularly reprinted in the United States, and two rival editions (New York and Boston, 1871) contain the suppressed pieces of his early volumes, and also some never collected by himself. His "Poems" have been translated into German by W. Herzberg (Dessau, 1854); "In Memoriam" by R. Waldmüller-Duboc (Hamburg, 2d ed., 1872) and Agnes von Bohlen (Berlin, 1874); and "Enoch Arden" by C. Hessel (Leipsic, 1874). "Enid" and "Elaine" have been translated into Spanish by Lope Gisbert (1875). His "Idyls of the King" have been illustrated by Doré. D. B. Brightwell has published a concordance to Tennyson's works (London, 1869).—See "Analysis of Tennyson's In Memoriam," by the Rev. F. W. Robertson (1867); "A Study of the Works of Alfred Tennyson," by E. C. Tanish (1868); and "Victorian Poets," by E. C. Stedman (1875).—FREDERICK, his elder brother, obtained at Cambridge a prize for a Greek poem in 1828, and in 1854 published "Days and Hours," a volume of poems.

**TENOR** (Lat. *tenere*, to hold), the second of the four parts in harmonic composition, reckoning from the bass, or the highest natural adult male voice, having a general compass from C, the second space in the bass, to A or B flat in the treble, though composers in chorus writing do not find it prudent often to write higher than G for this voice. The term is derived from the fact that in the ancient part compositions the tenor sustained or held the plain-song or principal air.

**TENSAS**, a N. E. parish of Louisiana, bordering on the Mississippi, and drained by Tensas river and Macon bayou; area, 680 sq. m.; pop. in 1875, 18,520, of whom 17,100 were colored. The surface is low and flat, and the soil fertile. It has steamboat communication with the interior by way of the Tensas river, which runs nearly parallel with the Mississippi, and joins the Washita in Catahoula parish to form Black river. The chief productions in 1870 were 94,500 bushels of Indian corn, 13,050 of sweet potatoes, and 25,371 bales of cotton. There were 1,211 horses, 2,404 mules and asses, 2,748 cattle, 1,043 sheep, and 2,684 swine. Capital, St. Joseph.

**TENT** (Lat. *tentorium*, from *tendere*, to stretch), a portable habitation, formed generally of cloth or skins stretched upon cords or frames, and supported by poles. Tents have always been the dwellings of nomadic tribes. The natives of the East brought them at an early period to a high state of perfection, and they are frequently mentioned in the Bible. The patriarchs were dwellers in tents, and St. Paul was a tent maker. Skins are first mentioned as a tent covering in Exodus xxvi. 14, where the tabernacle is ordered to be covered with rams' and badgers' skins. Tents of cloth made of camels' and goats' hair, like those of the Arabs of the present day, were also used. The Persian monarchs passed portions of the summer in tents in the mountains, and the custom of living in them during the hot months still prevails in the East. The Greeks encamped in tents at the siege of Troy, and the magnificence of the Persian tents and tent equipage is attested by many ancient writers. Tents were early used by the Roman armies, the first being made of skins or leather, and Hannibal's forces were provided with them when they crossed the Alps into Italy. The Roman *tabernaculum* resembled the house tent, and the *tentorium* the wedge tent of the present day.

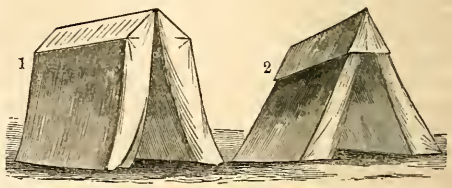

FIG. 1.—1. Roman Tabernaculum, from column of Trajan. 2. Tentorium, from column of Antonine.

A later and more elaborate tent was called *papilio;* it was probably circular, with a conical roof, but its exact form is not known. The armies of the crusades were provided with elaborate tents, and their Saracen antagonists were equally well furnished. Mediæval tents were sometimes of the most splendid description. The finest were very large, of the pavilion form, and divided into several apartments. Their hangings were frequently of silk and damask of many colors, and their cords and stay ropes of twisted gold.—Tents are said to have been first issued to modern armies by Louis XIV., but they were furnished only to certain privileged corps. According to Bardin, the Prussian army was the first regularly provided with them. Until near the middle of the 18th century there was little uniformity in their shape or quality. The earliest form in use in modern armies was probably the wedge tent, formed of a square piece of cloth over a ridge pole, and without stay ropes. A wedge tent rounded at one end and open at the other was called a *cannonière* in the French service in the last century. The *cortine* or *courtine* was an oblong wall tent, used by officers; when furnished with a fly or second roof, it was called a *marquise* or marquee. The use of tents in the French armies was almost abandoned after the begin-

ning of the revolution, and during the wars of the empire even the officers were rarely provided with them. It was not until about 1830, during the Algerian war, that the *tente abri* or shelter tent began to be regularly furnished to troops. This is made of two rectangular pieces of canvas, each 5 ft. 9 in. long and 5 ft. 4 in. wide, which are buttoned together and raised upon two sticks so as to form a roof open at both ends. Each soldier carries one of these pieces, one of the supporting sticks, and three pegs, which together weigh 3 lbs. 11 oz., and every two men are thus enabled to provide a shelter for themselves. This is still the French regulation tent, and was used in the Crimea, in Mexico, and in the Franco-German war. Besides this the French have three troop tents: the *bonnet de police*, which has the form of a triangular prism, to each end of which is joined a hemicone; the *tente elliptique* or Tacconet, a slight modification of the former; and the *tente conique* or *marabout*, a cone 22 ft. 4 in. in diameter at base and 10 ft. 8 in. high, with an interior curtain 14 in. high, which drops down around its base, leaving an interior diameter of 18 ft. 8 in. Each of these tents has two doors, opposite to each other. The French use also a marquee for general officers and a *tente de conseil*, the latter a round wall tent 20 ft. in diameter, with a conical roof. In the British service the use of tents was more generally adhered to after their introduction than in the continental armies. The troop tent principally used is the "bell" tent, a con-

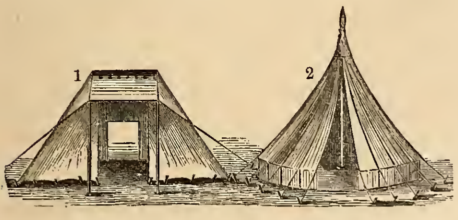

Fig. 2.—1. French Tente elliptique. 2. English Bell Tent.

ical-roofed round tent with a wall one or two feet high. Its diameter at the base is 14 ft. and its height 10 ft., and it is intended to shelter 12 to 15 men. The British have made but little use of shelter tents, although many models have been proposed. The Prussian troop tent is similar to the bell tent; but in the campaigns of 1866 and 1870 the German armies were not furnished with tents. In the Austrian service a "marching" tent is used, which resembles the French *bonnet de police*. It is 18 ft. long, 14 ft. wide, and about 7 ft. high, and accommodates 10 men. The Theurekauf troop tent is rectangular, and 26 ft. long by 22 ft. wide. It has a conical roof, with side walls 3 ft. high, and triangular end walls 7 ft. 6 in. high to the apex. An officers' tent, made after the same model, is also used. The Russian infantry tent is square, with a centre pole and four corner poles. It is 14 ft. in diameter and the side walls are 7 ft. high; it is intended for 14 men. The officers' tents are like those of the men, excepting that the roofs are of double canvas. The Italians use shelter tents, conical tents, and marquees. The shelter tent is formed of three rectangular sections, one of which is spread on the ground. The pieces are a little larger than those of the *tente abri*, and are supported by muskets instead of sticks. The conical tent, which is used by officers, is a modification of the French *tente conique.*

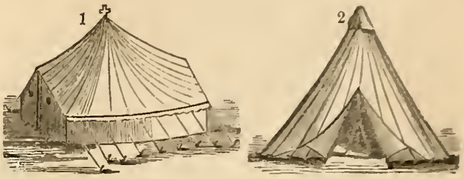

Fig. 3.—1. Theurekauf's Austrian Tent. 2. Sibley Tent.

A similar tent is in use in the Turkish army also, for both officers and men. In the United States the tents used most commonly have been the wedge, the Sibley, and the shelter. The wedge tent is 6 ft. 10 in. long, 8 ft. 4 in. wide, and 6 ft. 10 in. high; it is intended for five or six men. The Sibley tent is a modified Comanche lodge; it is a cone about 13 ft. high, with a diameter at base of 18 ft., and will shelter 12 or 14 men. During the last years of the civil war the shelter tent was used almost exclusively. The sections of the regulation tent are each 6 ft. long by 5 ft. 6 in. broad, and are made of cotton cloth with a coating of caoutchouc. Each section has a slit in it, through which the head may be passed, thus forming a poncho on the march, in rainy weather. It can also be used as a blanket. Shelter tents are sometimes formed in the American service into "half-faced camps," by fastening together two or three sections and stretching them from a ridge pole to the ground, thus making a back and roof. The triangular ends are then closed with other sections, and a fire built in the front, which is left open. This contrivance makes a very comfortable shelter, the heat which is reflected from the roof and sides keeping the men sufficiently warm.—The coverings of tents are now made generally of flax or cotton, hemp being rarely employed. The French tissue is of Belgian or Picardy flax, the English of the best long Baltic flax. The Austrian and the German canvas is also linen. The Italian government uses cotton canvas for large tents, and the Turkish government uses it altogether. In the United States army tents are made of cotton only, which is cheaper here than linen, while in Europe linen canvas can be produced at a lower price than cotton. The relative merits and demerits of the two tissues depend greatly on their mechanical structure and on

the quality of the materials used, but the weight of authority seems to favor cotton in preference to linen. In the beginning of the American civil war, when the price of cotton became excessive, the United States government purchased a large number of linen tents, but the troops objected to using them, and they were replaced by cotton ones.—*Hospital Tents.* In ancient times sick and wounded soldiers were treated in their general quarters. Tents specially set apart for the sick are said to have been first provided by Queen Isabella of Spain during the wars of Granada, but they did not come into general use. Invalids were occasionally treated in tents during the 17th and 18th centuries, but no organized tent hospitals, the records of which have any sanitary value, were established before the Crimean war. The enforced use of tents at Varna, made necessary by the absence of houses, first aroused attention to the subject of tent hospitals. The tent used was the hospital marquee of the British service, which is a double tent, a large one completely enveloping a smaller one, with an air space of about 18 in. between them. The inner tent is 28 ft. long, 15 ft. wide, and 12 ft. high in the middle, with walls 5 ft. high, and it has a floor cloth of painted canvas. It will accommodate 12 or 14 persons. The Prussian hospital tent, adopted in 1867, is house-shaped, double, supported by an iron frame, and large enough for 12 beds. In the Franco-German war a small square tent, supported by a light wooden frame and having a projecting pyramidal roof, was used. It was intended for but two beds, and was specially devoted to the treatment of those suffering from contagious diseases. The Turks have made use of a hospital tent which is described as of a long oval shape, supported by a pole at each end, and made of double canvas. The Russians, Austrians, and Italians have no special tent set apart for this purpose. The hospital tent used by the United

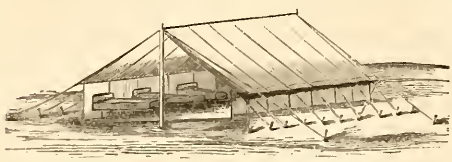

Fig. 4.—American Hospital Tent.

States government is a rectangular house tent, 14 by 15 ft. in diameter, and 11 ft. high in the centre, with a wall 4 ft. 6 in. high, and a fly forming a second roof which overlaps the wall about a foot. At one end it is furnished with a lapel so that two or more tents can be joined together to form one long tent. Each tent accommodates eight or ten patients.—See "The American Ambulance," by Dr. Thomas W. Evans (London, 1873).

**TENURE** (Lat. *tenere*, to hold), in its most general sense, the mode of holding property. In law it is usually confined to the manner of holding land or real property. The first grand division of tenures is into allodial tenures and feudal tenures. Of the word allodial, both the origin and the exact original meaning are uncertain. Practically it means a tenure which unites the right of the lord and the right of the tenant, or all right and title to or interest in the land. Hence, one who held land by allodial tenure had full and unencumbered possession of it, with an absolute right to use and dispose of it at his own pleasure, with no control of any one, and no responsibility to any one. An allodial holding stands in direct contrast with a feudal tenure, of which it was the essential quality that a tenant held it of a lord, and that tenant and lord had each their separate rights and interests in it and over it, or, in the language of the law, their separate estates in it. From this characteristic of allodial tenure, it is sometimes said that all the land in the United States is held by this tenure.—It seems to be generally admitted that previous to the prevalence of the feudal system the lands of European nations were held by allodial tenure, and that during the convulsions of the 9th, 10th, and 11th centuries, it became common for holders of land voluntarily to convert their allodial tenure into a feudal tenure, and so hold of some lord. One reason, and probably the strongest, was to obtain his support and protection in return for the allegiance of the tenant; but it may be believed that another cause of this change was the general desire to profit by the opportunity which the feudal system offered of escaping from the disordered and fragmentary condition of society then prevalent. This feudal system was nowhere more fully developed or more firmly established than in Normandy. It was therefore a matter of course that when William acquired England under a claim of title, but by the power of a feudal army which he carried with him, he should establish his victorious chiefs upon the land their arms had won under that feudal system which was admirably adapted to give to the sovereign lord, at any moment, a martial array that should combine nearly all the available force of the country, and be supported by all its available resources. He divided the land in unequal portions, observing that gradation of rank and of possession which constituted a characteristic feature of the system. While he who received a single manor became a baron and had his own court, they who received six or more were originally classed as greater barons; and to some of his principal chiefs he gave as many as 700 manors. In this way he divided most of the valuable land of England. His immediate successors followed the same system, and before a century had elapsed the feudal system and the feudal tenures were established over nearly all England. All these tenures rested upon the fee (see FEE); but they were very various, and divided the interest in and the beneficiary use of the land, between

the lord and the vassal, in very different proportions. There were generally many lords, for the system of subinfeudation prevailed, and the vassal held of his immediate lord, he of the next higher, and he of the next, the series always going up to and ending with the sovereign. Hence we may say that all tenure rested upon two principles: one, that all land was held of the sovereign, who retained certain rights and interests therein; the other, that all the rights and interests of all the lords, and of the tenant finally in possession, added together, constituted that allodial tenure already mentioned. There were various kinds of tenure, as for example tenure by copyhold, tenure in gavelkind, and the tenure of borough English. Of copyhold there is nothing in the United States. The principal feature of tenure in gavelkind was that all the sons inherited equally and together, instead of the eldest son alone, which latter is the rule of the feudal system, and is nearly universal in England. (See Gavelkind, and Heir.) Of tenure by borough English, the essential principle is, that neither the eldest nor all the sons inherit, but the youngest takes as heir. For this strange custom Littleton accounts by the lesser ability of the youngest son to take care of himself; but a custom prevalent in many parts of the United States offers a more probable explanation of this tenure. It is common in New England, for example, for the eldest son, as he comes to maturity, to receive what assistance his father can give, which is considered as his share of the estate; the same thing is done with other sons as they reach full age; until at length only the youngest son is left to take charge of his parents. When they die he has the homestead; or while they live they relinquish it to him, taking his obligation or trusting to his affection for support. The same custom is said to exist in Tyrol, Bavaria, and other parts of Germany.—The tenure with which we have most concern is that of socage. This was wholly liberated from the stringent military services which generally prevailed, and the civil services on which land was held under it were for the most part easy and honorable. At an early period it became known as "free and common socage," and as this tenure spread over England, the severities, restrictions, and encumbrances of the common feudal tenures passed away, until this process was completed by the statute 12 Charles II. (1661), and nearly all the old feudal tenures (all in fact which were in any way burdensome or restrictive of the proper rights of the tenant) were reduced to the tenure of free and common socage. This tenure has all the actual advantages of allodial ownership. The beneficial use which one who holds by this tenure has in the land comprises, for all practical purposes, a sole, undivided, and unencumbered interest. Escheat remains as a feudal incident to the tenure, but the lord cannot profit by it if the tenant has an heir or chooses to make a will. The tenant in fee simple of lands held in free and common socage can make any disposition of them, and carve any estates out of them, which the law of real estate permits; and any one to whom he grants it by sale or gift, or devises it by will, takes title directly from the grantor or testator, and his title is complete without the consent or concurrence of the lord or any action whatever on his part. It may be added that this tenure, unlike most other feudal tenures, has no reference whatever to the rank or occupation of the tenant, or to the purposes to which the lands are applied. This was the tenure created or prescribed by all the early colonial charters or patents from which our titles are now derived; as the charter of Virginia in 1606; the patent of New England in 1620; the charter of Massachusetts in 1629; of Maryland in 1632; of the province of Maine in 1639; of Connecticut in 1662; of Carolina in 1663; of Rhode Island in 1663; of Pennsylvania in 1681; the act of the general assembly of the colony of New York in 1691; and the charter of Georgia in 1732. But in New York, Pennsylvania, Connecticut, and Michigan all feudal tenures, including of course that of free and common socage, are abolished by statute; and it seems to be held, that under the provisions of the ordinance of 1787 the doctrine of tenures is not in force in any of the states formed out of the territory to which that ordinance applied. Substantially, our tenure unites what is best in both the allodial tenure and that by free and common socage. Nor is the fact without its historical value, that the allodial tenure, which formerly prevailed over all Europe, among all the nations who were the ancestors of European nations and so of our own, after being displaced for more than 1,000 years by the feudal system, is at length reëstablished in full force throughout the United States. And yet there are reasons for thinking the tenure of free and common socage, freed as it certainly is now from all feudal encumbrance, explains and illustrates our law of real estate better than the other theory. One reason is, that the principles of the feudal system do in fact underlie all the doctrines and all the forms of the common law in regard to real estate; and wherever the common law prevails, which it does in all the states excepting Louisiana (where the municipal law is founded upon the Roman civil law), the principles of the feudal law and of feudal tenure must be understood and made use of. Another reason is, that the law of escheat is universal with us (see Escheat), and it is governed by the law of feudal tenure, modified by our statutes. A third reason is, that the important and universal law of eminent domain is far better understood and applied by the theory that all property is held from the sovereign, that is, the state or people; and that in the original grant on which all title is founded, the sovereign reserved the right to resume the same for his own, that is,

for the public use, on making adequate compensation. Yet another reason is, that the obligation of fealty remains in full force. It is now and here an obligation only to the sovereign. It is implied, or rather it is expressed, in the oath of allegiance; but it does not depend on this oath. It is the obligation and the duty which rest on every citizen of the United States, as the condition upon which he holds all property, all interests, and all rights, to be "feall and loiall," as the old law expressed it, to be faithful and loyal to his sovereign, that is, to the state and to the Union.

**TEOCALLI.** See MEXICO, vol. xi., p. 474.

**TEOS,** an ancient Ionian city, on the W. coast of Asia Minor, about 25 m. S. W. of Smyrna. It is noted as the birthplace of Anacreon. It had two good harbors, and was a flourishing commercial town till the Persian conquest. The village of Sighajik, 1½ m. N. of Teos, has walls constructed from its ruins. The chief ruin is that of the temple of Bacchus.

**TEPLITZ,** or **Töplitz,** a watering place of N. Bohemia, in the circle of Leitmeritz, 45 m. N. W. of Prague; pop. in 1870, including the adjoining village of Schönau, 11,618. In the season of 1875 it was visited by about 30,000 invalids and tourists. Of the 17 alkalo-saline springs, 11 are now used, chiefly for the gout and rheumatism. A treaty of alliance between Russia, Prussia, and Austria, against Napoleon, was concluded here, Sept. 9, 1813.

**TEQUENDAMA, Falls of.** See BOGOTÁ.

**TERAMO. I.** A province of S. Italy, formerly Abruzzo Ulteriore I. (See ABRUZZO). **II.** A town, capital of the province (anc. *Interamna*), 85 m. N. E. of Rome; pop. about 19,000. It is the see of a bishop, and has a modernized Gothic cathedral, and manufactories of hats and cream of tartar. Interamna, which is also the ancient name of Terni and other places, was a city of Picenum. Many vestiges of the ancient city have been discovered on the site of Teramo.

**TERATOLOGY** (Gr. τέρας, a wonder or monster, and λόγος, discourse), that branch of physiological science which treats of the malformations and monstrosities of plants and animals. On account of its greater interest, more attention has been given to the latter, particularly within the present century, by French and German physiologists. There was no attempt to systematize the study of monstrosities till the time of Isidore Geoffroy Saint-Hilaire, who gave the science the above name. His classification is given in the article MONSTER. He divides the history of monstrosities into three periods, viz.: the fabulous, the positive, and the scientific. The fabulous period is all that prior to the 18th century; the positive embraces the first half of the 18th century; while the scientific dates from the middle of that century. In the fabulous period the prevalent belief attributed the formation of human monsters to divine anger as punishments to parents, or to demoniacal influence, and as the progeny of the devil they were destroyed. As late as the beginning of the 17th century it was said by learned men that children with six fingers were made in the image of the devil, and a remnant of such superstition still exists. The first important work was published by Leicetus in 1616, in which he gives a great collection of the most fabulous monsters. He quotes largely from a work on monsters by Lycosthenes (1557), and his pages abound in wonders. A work published by Haller in 1768 is the first which may be regarded as scientific. Buffon gives a classification of monsters in his "Natural History." Meckel, the celebrated physiologist, published a complete treatise on monsters in his *Handbuch der pathologischen Anatomie* (1812–'18), and Tiedemann makes important observations on the genesis of monsters in his *Anatomie der kopflosen Missgeburten* (1813). Works of the greatest importance were those of the two Geoffroy Saint-Hilaires (1822, 1829, and 1832–'6). A work on monsters in Dutch and Latin, by W. Vrolik, is one of the most complete manuals on teratology (Amsterdam, 1840–'42; new ed., fol., with 100 plates, 1849), and contains the most complete atlas that has ever been published. See also articles in the transactions of the New York state medical society for 1865, '66, '67, and '68, on "Diploteratology," by Dr. J. G. Fisher of Sing Sing, N. Y., giving a brief history of the subject of teratology, adding to the classification, and giving also the history of many cases of double monsters; J. North, "Lectures on Monstrosities" (London "Lancet," 1840); Allen Thompson, "Remarks upon the Early Condition and Probable Origin of Double Monsters," in "London and Edinburgh Monthly Journal of the Medical Sciences" (1844); J. Vogel, *Pathologische Anatomie des Menschlichen Körpers* (Leipsic, 1845); C. Rokitansky, *Lehrbuch der pathologischen Anatomie* (Vienna, 1851–'61); William F. Montgomery, "Account of a very remarkable Case of Double Monster," &c., in "Dublin Quarterly Journal of the Medical Sciences" (1853); A. Förster, *Die Missbildungen des Menschen* (2 vols. 4to, with 26 plates, Jena, 1861); and M. Lerboullet, *Recherches sur les monstruosités du brochet observées dans l'œuf, et sur leur mode de production*, in the *Annales des sciences naturelles* (Paris, 1863).

**TERBIUM,** a supposed metal discovered by Mosander in 1843, associated with erbium and yttrium in the mineral gadolinite. Very carefully conducted experiments of Bahr and Bunsen throw great doubt on the existence of terbium, and further experiments are required to afford a perfectly satisfactory answer to the question whether crude yttria is a mixture of three earths or of only two. According to Delafontaine, terbia is an earth of a pale rose color, the solutions of which exhibit an absorption spectrum, whereas the salts of erbia do not exhibit the same phenomenon by prismatic analysis. The metal terbium has never

been isolated, and a majority of chemists at present discredit its existence.

**TERBURG, Gerard,** a Dutch painter, born in Zwolle in 1608, died in Deventer in 1681. He painted cabinet size conversation pieces, musical parties, and ladies at their toilets. In 1648 he painted a picture of the plenipotentiaries assembled at the congress of Münster, which led to his being invited to Madrid by Philip IV. He excelled in color and the finishing of his draperies, especially white satin.

**TERCEIRA,** one of the Azore islands, near the centre of the group; lat. 38° 40′ N., lon. 27° 10′ W.; extreme length 20 m., general breadth about 12 m.; pop. about 50,000. The coast is generally bold and precipitous, and the central part of the island is mountainous, the summits consisting mostly of fertile plains. Many of the mountain masses are composed of soft pumice. The island is well watered, and the soil fertile. Grain, wine, and cattle are produced, and it exports oranges and lemons. Capital, Angra.—In 1829 Terceira became the seat of the regency for Dona Maria da Gloria during Dom Miguel's usurpation in Portugal, and Dom Pedro I. of Brazil collected there forces for the recovery of his daughter's throne.

**TEREDO.** See Ship Worm.

**TERENCE** (Publius Terentius Afer), a Roman comic poet, born in Carthage about 195 B. C., died about 159. He became a slave of P. Terentius Lucanus, a Roman senator, who gave him an excellent education, and finally freed him. The *Andria*, his first play, was acted in 166, and its success introduced him into the best society of Rome, Lælius and the younger Scipio being among his associates. Later in life he went to Greece, and there translated 108 of Menander's comedies. The manner of his death is uncertain, though the common account ascribes it to grief at the loss of all his translations of Menander. Six of his comedies are extant, and besides the *Andria* ("The Woman of Andros"), the plot of which was adopted by Steele in his "Conscious Lovers," there are *Hecyra* ("The Stepmother"), produced in 165; *Heauton - Timoroumenos* ("The Self-Tormentor"), produced in 163; *Eunuchus* ("The Eunuch"), the most popular of his plays, for which he received 8,000 sesterces, produced in 162; *Phormio*, produced in 162; and *Adelphi* ("The Brothers"), acted first in 160. The dramas of Terence all belong to the *fabula palliata*, and with the exception of the last two were first performed at the Megalesian games. The plots were borrowed from Menander. Terence's Latinity is elegant, and his works have been handed down in a very correct state. There have been numerous imitations of his comedies by the moderns, and they have been translated into nearly all the languages of Europe. The first edition is probably that of Milan (fol., 1470). Recent editions of the text with notes are those of Davies (London, 1869), Wagner (London, 1869), and Umpfenbach (Berlin, 1870). Among English translations are those of Colman (London, 1765), Patrick (Dublin, 1829), and Riley (London, 1853).

**TERHUNE, Mary Virginia** (Hawes), an American novelist, under the pseudonyme of Marion Harland, born in Amelia county, Va., about 1835. At the age of 16 she published in "Godey's Lady's Book" a sketch entitled "Marrying from Prudential Motives," which was copied into an English periodical, translated into French, retranslated into English, and published in England and America as an English tale. In 1856 she married the Rev. E. P. Terhune, and since 1859 has resided at Newark, N. J. Her works are: "Alone" (Richmond, 1854; 19th ed., 1856); "The Hidden Path" (New York, 1855); "Moss Side" (1857); "Miriam" and "Nemesis" (1860); "Husks" (1863); "Husbands and Homes" (1865); "Sunnybank" (1866); "The Christmas Holly" (1867); "Ruby's Husband" (1868); "Phemie's Temptation" (1869); "Helen Gardner," "The Empty Heart," "Common Sense in the Household, a Manual of Practical Housewifery," and "At Last" (1870); "True as Steel" (1872); "Jessamine" (1873); and "From my Youth Up" (1874).

**TERMINI-IMERESE** (anc. *Thermæ Himerenses*), a town of Sicily, part of the ancient northern Himera, in the province and 20 m. S. E. of the city of Palermo, E. of the mouth of the San Lionardo; pop. in 1872, 25,780. It has fine churches, a good harbor, fisheries, and an active trade in local products, including maccaroni, which is the best in Sicily.—After the destruction of the Greek city of Himera by Hannibal, the son of Gisco, in 409 B. C., the surviving inhabitants fled to the neighboring Thermæ, so named from its celebrated hot sulphur springs. The town appears to have existed during the Roman empire, and considerable portions of the Roman part are still visible. The southern Thermæ or Thermæ Selinuntiæ is described under Sciacca, its modern site. (See also Himera.)

**TERMITES,** the proper name of the white ants, or the neuropterous insects of the family *termitinæ*. Though they resemble the common ants (*formica*) in their social habits, they belong to a different order, and in many respects come near the orthoptera. In the genus *termes* (Linn.) the antennæ are thread-shaped, with about 20 joints; the eyes small but prominent, and the ocelli three; the mouth as in orthoptera; thorax distinct, and wings large, long, and membranous; legs short with four-jointed tarsi; abdomen with a pair of minute caudal appendages. They live in vast communities, principally in the tropics, and do great damage by devouring everything but metals and stone which comes in their way, gnawing even the interior of the beams of houses, leaving only a thin shell. According to Latreille there are five classes in their communities, males, females, workers, neuters, and soldiers. The males and females are at first

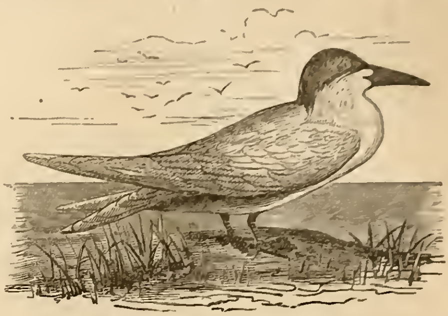
exactly alike, and are furnished with four very long, nearly equal wings; after impregnation the abdomen increases greatly from the immense number of eggs which it contains; as many as 80,000 may be laid by one female in 24 hours, making about 30,000,000 in a year. Most of the community is made up of wingless individuals, resembling the winged insects, but without eyes; these are the workers, which perform all the labors of construction. Others without wings, apparently pupæ, resemble the workers, but have four tubercular wing cases on the thorax; these are supposed to be neuters or incomplete females, which attend upon the king and queen and take care of the young brood; the extraordinary fecundity of these ants renders necessary a large class of neuters, which possess the affections of maternity without the power of reproduction. The fifth class, apparently neuters still further developed, have very large jaws, and are the soldiers and defenders of the rest. From the researches of Fritz Müller ("Nature," 1874) it appears that, unlike the social hymenoptera, the neuters of the termites are not sterile females, but modified larvæ which undergo no further metamorphosis; that both sexes are represented among the neuters; and that there are in many (if not in all) species two forms of sexual individuals, winged and wingless males and females; the former produced in vast numbers, leaving the nest, and most of them perishing; the latter never leaving the termitary where they were born. The constitution of their societies in its general characteristics does not vary essentially from that noticed under ANT. They make edifices of a most remarkable size and complexity, usually on the ground, but sometimes among branches of trees and in houses, communicating with the ground by long spiral galleries. When on the ground, the most usual shape is that of a group of irregular cones, frequently 12 ft. high, looking like huts of the natives, and so firmly constructed that man and beast can stand on them securely; they are built of earth softened in the jaws of the workers, which dries quickly and becomes very hard. A nest is divided internally into numerous chambers and galleries, in one of which the queen is imprisoned, and waited upon by numerous special attendants whose apartments are in close proximity to the royal cell; the male is said to lie concealed under one side of the enlarged abdomen of the female. The attendants carry off the eggs as soon as they are laid into separate chambers, where the young when hatched are tended by the nurses. There are generally two or three roofs within the dome-shaped interior, and the thick walls are perforated by passages leading in various directions to the nurseries, magazines of food, ground floor, and subterranean entrances; the food consists principally of decaying and dried wood, though gums and thickened vegetable juices are stored in their magazines. The king and queen have no regal authority. Destructive as the termites often are, they play a most important part in the economy of nature by removing decaying wood, which otherwise in a short time would seriously interfere with vegetation in the tropics.—The largest and best known species is the warrior white ant of Africa (*T. fatalis*, Linn., or *T. bellicosus*, Smeath.); in each nest there are a king and queen, and about 100 workers to one soldier; the workers are about a quarter of an inch long, always busy and very fast runners; the soldiers, which appear to be the same further developed, are about half an inch long, and the perfect insects from $\frac{6}{10}$ to $\frac{7}{10}$ of an inch long; it is supposed

Nest of the White Ant (Termes bellicosus).
1. Male. 2. Gravid female. 3, 4, 5. Neuters.

that two or three years are requisite for the full development of the species from the egg. Toward the commencement of the rainy season the perfect insects take flight, but are mostly destroyed by the heavy rains; if a pair escape, they are taken by some of the workers which are always running over the ground, and are made the king and queen of a new colony. The pregnant female has the abdomen 3 to 5 in. long and two thirds of an inch wide, about 2,000 times as large as the rest of her body, and 20,000 to 30,000 times as large as that of the workers. The bite of the soldiers is very severe and painful, but not dangerous to a healthy person; they permit themselves to be torn asunder rather than let go their hold. They have many enemies in other ants, birds, and reptiles, which destroy great numbers; the wingless ones are also devoured with avid-

ity by the natives and even by Europeans, who roast them in the manner of coffee. (See "Insect Architecture," by James Rennie, in the "Library of Entertaining Knowledge," London, 1830-'31).—There are other species in tropical Asia, and even two or three in southern Europe. In the United States a representative species, the *T. frontalis* (Haldeman), has been noticed at Salem, Mass., where it did considerable mischief in greenhouses and graperies, not only attacking decaying and dead wood, but also excavating the roots of living vines and causing their destruction. (See "Proceedings of the Boston Society of Natural History," vol. vii., pp. 287, 288, May 2, 1860.)

**TERN,** the proper name of the birds of the gull family and subfamily *sterninæ*, among which is included the noddy, previously described. The terns have a rather long, usually slender, nearly straight, and sharp-pointed bill; wings elongated, with long and pointed primaries; tail long, and in most species forked; tarsi slender, anterior toes with a deeply notched web, hind toe small, and the claws curved and sharp. They are found on and near the sea shore, and sometimes on inland lakes and rivers, most of the time hovering with rapid and easy flight over sandy bars and shallows, darting suddenly upon small fishes and crustaceans; they are often seen swimming and resting on the water, but never diving; from their forked tail, small size, and swift and graceful flight, they are popularly called sea swallows.—In the typical genus *sterna* (Linn.) the upper mandible is slightly curved, with the frontal feathers extending to the nostrils; the outer quill is the longest. It contains more than 60 species, in both hemispheres, migrating in bands from place to place according to season; the eggs are two to four, usually deposited in a slight hollow in the sand on rocks surrounded by the sea; the hatching is left mostly to the sun, the females sitting only at night and in cold weather; the young are carefully fed and bravely defended. The largest species is the Caspian tern (*S. Caspia*, Pall.), 21½ in. long, 51 in. in alar extent, with a very stout bill of 3 in.; the back and wings are pale bluish ash, the upper parts of the head black with a greenish gloss, the quill shafts and the under plumage pure white, the bill vermilion, and the legs and feet black; the tail is not much forked; the young are mottled above with blackish brown. It is found in the United States from the coast of New Jersey northward, and all over Europe, in the vicinity of the Caspian sea (where it was first found and described by Pallas), and also in Africa. The eggs, as in most of the terns, are yellowish stone-colored, with ash-gray and dark reddish brown spots; they are 2½ by 1⅔ in. The Cayenne or royal tern (*S. Cayana*, Bonap.) is 21 in. long and 49 in. in alar extent, with a deep red bill of 2¾ in.; the mantle is bluish gray, lower parts white, legs and feet black, and the tail forked. It is found on the Atlantic coast from Labrador to Florida, being abundant about the southern keys; it also occurs in California. It is very shy, and utters loud and harsh cries during flight; when any are killed



Cayenne Tern (Sterna Cayana).

out of a flock, the rest dart toward the gunner; when wounded they eject the contents of the stomach, and bite severely; the eggs are 2¾ by 1¾ in., and like those of the other species afford good eating; the flesh is very oily. The sooty tern (*S. fuliginosa*, Gmel.) is 16½ in. long and 35 in. in alar extent; bill 1¾ in. and black, as are the legs and feet; it is deep black above, the forehead and lower parts white; tail deeply forked, black, with the outer and basal half of the inner web of the outside feathers white. It is found in the gulf states from Texas to Florida, arriving from the south in May and departing by the beginning of August; it rarely alights on the water, where it would be incommoded by its long tail; it feeds principally on fish, which it seizes by a sweeping curve; the cries are very loud when the breeding places are disturbed; the eggs are three in number, 2¼ by 1½ in., and in former times were the source of a considerable trade with Havana. Wilson's tern (*S. Wilsoni*, Bonap.) is 15 in. long, with an alar extent of 32 in.; the bill is 1⅝ in., slender, coral red, black near the end with a yellow tip; mantle light grayish blue; upper part of head and neck deep black; beneath pearl-gray; tail deeply forked, with the outer web of lateral feather blackish gray; legs and feet coral red. It is found from Texas to Labrador, and on the coast of Massachusetts goes by the name of mackerel gull, from the supposition that it announces the arrival of this fish in its summer quarters; it formerly bred on Egg Rock near Nahant, and was very abundant in summer on Nantasket beach; the eggs are three, 1¾ by 1¼ in. Its European representative is the common sea swallow (*S. hirundo*, Linn.), spread over Europe and Africa; it is 14¼ in. long, and the eggs 1⅝ by 1⅛ in. The arctic tern (*S. macrura*, Naum.) is 14½ in. long, and 32 in. in extent of wings; the bill 1⅛ in., slender, and deep carmine; mantle light grayish blue, and under parts plumbeous gray; tail very deeply forked; legs and feet crimson. It is found from the coast of New England to the arctic seas and the fur countries, also

coming down to N. Europe; it is a very rapid and graceful flier, dashing boldly into the water after fish and shrimps; the eggs are delicious, 1¼ by ⅝ in. There are several other species, and another genus, the short-tailed or black tern, *hydrochelidon* (Boie), with the species *H. plumbea* in America and *H. nigra* in Europe.

**TERNATE.** See MOLUCCAS.

**TERNAUX. I. Guillaume Louis,** baron, a French manufacturer, born in Sedan, Oct. 8, 1763, died in St. Ouen, April 2, 1833. When scarcely 16 years old he managed his father's woollen factory, and retrieved the fortune of his family. He was a supporter of reform in 1789, but was one of the king's defenders in 1792. After the fall of Robespierre he established large manufactories at Louviers and Sedan. He naturalized Thibetan goats in France, and manufactured shawls in imitation of the Indian ones, known as *cachemires-Ternaux.* He was made a baron by Louis XVIII.; in 1818 he was elected a deputy; was reëlected in 1827, and was one of the 221 deputies whose decided stand against the government brought about the revolution of July, 1830. The commercial crisis which followed ruined him, though he paid all his debts. He published several treatises on finance and manufactures. **II. Henri,** nephew of the preceding, known as Henri Ternaux-Campans, born in Paris in 1807, died there in 1864. He was distinguished for his devotion to the study of American history, and published two series, in 10 vols. each, of *Voyages, relations et mémoires*, from inedited Spanish manuscripts, relating to the discovery and conquest of America (Paris, 1836–'40); *Bibliothèque américaine*, 1493–1700 (8vo, 1837); *Bibliothèque asiatique et africaine* (1841–'2); and various other works.—MORTIMER, his brother, born in Paris in 1808, has published *La chute de la royauté*, 10 *août* 1792 (1864); *Le peuple aux Tuileries*, 20 *juin* 1792 (1864); and *Histoire de la terreur* (1792–'4), from inedited documents (7 vols. 8vo, 1862–'9).

**TERNI** (anc. *Interamna*), a town of Italy, in the province of Perugia, on an island formed by the Nera, 49 m. N. by E. of Rome; pop. about 10,000. It has a cathedral built from the designs of Bernini, with a high altar rich in marbles; and there are many Roman remains and inscriptions. Silk and oil are the chief articles of trade. About 5 m. from Terni are the celebrated falls of the Velino (*cadute delle Marmore*), about 800 ft. high, fed by an artificial channel laid out by the Romans to drain the plains of Rieti. The water descends by three separate leaps, respectively 50, 500, and 250 ft. high, forming one continuous sheet of foam, described by Byron "as worth all the cascades and torrents of Switzerland put together."—The ancient Interamna, originally belonging to Umbria, was celebrated under the Romans, as Terni still is, for the remarkable fertility of the surrounding country.

**TERPANDER** (Τέρπανδρος), a Greek musician, born at Antissa in the island of Lesbos, flourished in the earlier half of the 7th century B. C. He removed to Sparta, where in 676 he was crowned victor in the first musical contest at the feast of Apollo Carneius, and where he established the first musical school or system in Greece. He enlarged the compass of the lyre from a tetrachord to an octave, but with the omission of the third string, counting from the highest down, making it really a heptachord; and he was the first who regularly set poetry to music.

**TERPSICHORE,** one of the nine Muses, daughter of Jupiter and Mnemosyne. She presided over choral song and dancing, and is generally represented as crowned with flowers and holding a lyre and plectrum.

**TERRA,** or **Tellus,** a goddess of the Roman mythology, in whose form the earth was personified and worshipped, and who is thus often named in contrast with Jupiter, the god of heaven. A festival in her honor was celebrated on the 15th of April, and private sacrifices were offered to her at seedtime and harvest, and also when any member of a family died. Terra corresponds to Gæa or Ge in Greek mythology. In the Hesiodic theogony Gæa was the first born of Chaos. She gave birth to Uranus, whom she afterward married, and from this union sprang the Titans, the Cyclops, and the hundred-handed giants. Her worship was universal among the Greeks.

**TERRACINA,** a town of Italy, in the province of Rome, on a gulf of its own name in the Mediterranean, at the S. W. end of the Pontine marshes, 26 m. S. W. of Frosinone; pop. about 5,000. It has a cathedral occupying, according to some authorities, the site of the celebrated ancient temple of Jupiter Anxur, from which its beautiful fluted marble columns are said to have been taken. The most picturesque of the many ruins are those of the palace of Theodoric, on the summit of the hill above the town. Near the shore is a palace built by Pius VI., who made considerable but not successful efforts to drain the marshes and to restore the ancient port, which is still filled with sand, though a new pier affords protection to small craft. The bishopric of Terracina is said to date from A. D. 46.—Terracina was the Anxur of the Volscians and the Romans; the latter had fine villas and a naval station here, and also called the place Tarracina.

**TERRA COTTA** (It., baked clay), an earthenware employed by the ancient Greeks and Egyptians in the manufacture of moulds, architectural ornaments, statuary, utensils, sarcophagi, and various other objects. An important use of it among the Assyrians and Babylonians was for the preservation of records, which were stamped upon terra cotta slabs and cylinders. The material is clay of considerable purity, and the articles are generally slack-baked, or merely hardened by continued exposure to the sun. The color is usually a red or buff, and the vases are often ornamented with designs of leaves, vines, &c., painted

in black or other colors. While these adorn the rim, neck, and stand, the body is sometimes covered with allegorical representations of gods, men, and animals. The Romans employed finer materials for their terra cottas, and moulded these into lamps, urns, &c., which they ornamented with depressed or raised figures. From the 12th to the 17th century terra cotta was much used in Italy for architectural decorations, and Michel Angelo and other sculptors employed it for their models and clay sketches. The manufacture of decorative works in terra cotta has been an important branch of industry in England since the latter part of the 18th century. The mixtures employed are of pure clays and fine quartz sand or calcined flints with pulverized potsherds or old pottery. The coats of arms seen over many of the shop fronts in London are moulded and baked in this material. It is also used for statues, baptismal fonts, fountains, and ornamental pieces of various forms in different parts of buildings. The ware is much more firmly baked than that of the ancients. Of late years it has been extensively employed for elaborate architectural ornaments, such as are ordinarily carved in stone, and also for architectural models. Drain tiles and similar ware are made of it. It is also an important manufacture in France, and there was a remarkable display of terra cotta statues and other objects in the Paris exhibition of 1867.

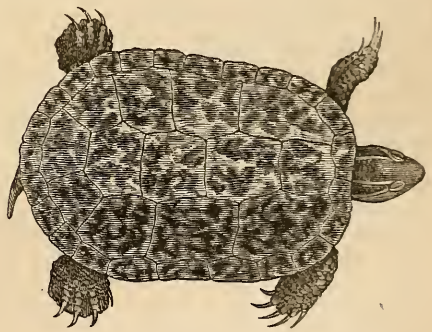
**TERRA DEL FUEGO.** See Tierra Del Fuego.

**TERRA DI BARI.** See Bari.

**TERRA DI LAVORO.** See Caserta.

**TERRA D'OTRANTO.** See Lecce.

**TERRAPIN,** a name commonly applied to several species of land tortoises, but in the United States generally limited to the few freshwater species of the family *emydoidæ*, extensively used as food. They have a depressed head, and the neck can be wholly retracted within the shell; eyes large, and the beak somewhat like that of a bird of prey; they are good swimmers, and out of the water move with more quickness than the land tortoises; their food consists of small reptiles, fish, and other aquatic animals, though in captivity they eat vegetables readily.—The yellow-bellied terrapin (*trachemys scabra*, Ag.; *emys serrata*, Daud.) is 12 in. long, 7½ in. wide, and about 11 in. high; the shell is rounded, very convex, notched in front, deeply serrated behind, wrinkled longitudinally, and rough all over. The color is blackish brown with yellow lines and marks more or less radiating; sternum yellowish, notched behind; snout short and pointed; upper jaw with a very slight notch; eyes large, with golden iris having a broad black stripe extending horizontally through it; fingers five, each with a short strong nail, and toes five, fully webbed, four only having nails; tail short, thick, and pointed; head and limbs black, varied with yellow lines, a broad transverse band of the latter across the neck behind the eyes. This species lives in stagnant ponds and pools, and is fond of basking in the sun on the margins and on stones and stumps, whence it can readily plunge into the water if disturbed; it is found from Virginia to Georgia, south of the latter being replaced by the Florida and north of the former by the red-bellied terrapin; it is abundant about Charleston, S. C., where it is seen in great numbers in the markets.—The red-bellied terrapin, or potter (*ptychemys rugosa*, Ag.; *E. rubriventris*, Le Conte), is 11 in. long, 7 in. wide, and about 5 in. high; the shell is entire in front, widest and notched behind; upper jaw deeply notched, and the lower serrated with three teeth in front; shell, head, neck, and limbs dusky brown, with blotches, spots, and lines of red; sternum dusky red. It lives in running waters, preferring rocky bottom; it is found between the Delaware river and Chesapeake bay, and is abundant about Trenton, N. J.; its flesh is less esteemed than that of the preceding and following species.—The Florida terrapin (*P. concinna*, Ag.; *E. Floridana*, Harlan) is the largest of the species, being 15 in. long, 10 in. wide, and 7¼ in. high; the shell is entire, compressed on the sides;



Red-bellied Terrapin (Ptychemys rugosa).

the jaws without teeth, the lower somewhat serrated; the shell, neck, head, and limbs brownish, with numerous yellow lines and bands; sternum pale yellow, the marginal plates with a black spot having a yellow centre; throat ashy, striped with yellow. It is extensively distributed through the southern states, in lakes and rivers, from North Carolina as far as western Louisiana, and up the Mississippi valley to Arkansas; it is very common in E. Florida, especially in the St. John's river; its flesh is delicious.—The chicken terrapin (*deirochelys reticulata*, Ag.; *E. reticulata*, Schweig.) is 9½ in. long and 5½ in. wide; the shell is oval, entire, longitudinally rough; upper jaw slightly notched, lower entire with a hook in front; neck very long; above, head, neck, and limbs dark brown, with numerous yellow lines communicating so as to form a network, whence the specific name; lower parts yellow, with black spots on some of the marginal plates. Its habits are the same as in the other species, the long neck giving it

in the water somewhat the appearance of a snake, as it swims with this part and the head alone visible above the surface. It is found from North Carolina and Georgia to Louisiana, not far from the sea coast; it is often brought to market, and is the most esteemed of the terrapins for food.—The salt-water terrapin (*malacoclemmys palustris*, Ag.; *E. terrapin*, Holbr.) is 7½ in. long and 3 in. high; the shell is nearly entire, slightly notched posteriorly; the head is very large; jaws strong and cutting, the upper slightly notched and the lower hooked; eyes small with a gray iris; neck short and thick. The color is dusky olive-green, with darker concentric lines; sternum generally yellowish with concentric dusky lines; side of the head, neck, and limbs brownish white with innumerable black dots; the males are the smaller, and have deeper striæ. It lives in salt water and in salt marshes, where it hibernates; it is very shy, a rapid swimmer, and a quick runner on land; it is found from Rhode Island to Florida, along the gulf of Mexico, in South America, and perhaps in the West Indies; it is abundant about Charleston, S. C.; the flesh is excellent, and in the middle states most esteemed during hibernation.

**TERRE BONNE**, a S. E. parish of Louisiana, bordering on the gulf of Mexico, and drained by the Terre Bonne, Black, and Caillou bayous; area, 1,640 sq. m.; pop. in 1875, 15,486, of whom 7,988 were colored. The surface is flat and marshy, and diversified by numerous shallow lakes. Morgan's Louisiana and Texas railroad intersects the N. part. The chief productions in 1870 were 209,050 bushels of Indian corn, 233,000 lbs. of rice, 130 bales of cotton, 6,537 hogsheads of sugar, and 366,282 gallons of molasses. There were 676 horses, 1,798 mules and asses, 696 milch cows, 1,357 other cattle, and 2,426 swine; 4 saw mills, 64 manufactories of molasses and sugar, and 4 of upholstery. Capital, Houma.

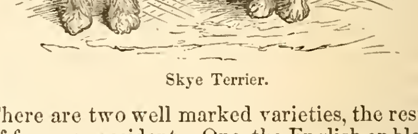
**TERREBONNE**, a S. W. county of Quebec, Canada, on the N. bank of the St. Lawrence, opposite Montreal; area, 541 sq. m.; pop. in 1871, 19,591, of whom 18,151 were of French and 970 of Irish origin or descent. It is drained by the North river, an affluent of the Ottawa, and by several streams that empty into the St. Lawrence. Capital, St. Jerome.

**TERRE HAUTE**, a city and the capital of Vigo co., Indiana, on the E. bank of the Wabash river, here spanned by three bridges, 70 m. W. S. W. of Indianapolis, and 55 m. N. of Vincennes; pop. in 1850, 4,051; in 1860, 8,594; in 1870, 16,103. It is situated on an elevated plateau, is well built, and has broad streets ornamented with shade trees. It is the centre of trade for a rich and populous region, abounding in coal. It is connected with Lake Erie by the Wabash and Erie canal. The Wabash river is navigable a portion of the year for steamboats, and shipments are made direct to and from points on the Ohio and Mississippi rivers. The city is an important railroad centre, being the point of intersection of seven lines, viz.: the Cincinnati and Terre Haute; Evansville, Terre Haute, and Chicago; Terre Haute, Paris, and Decatur; Evansville and Crawfordsville; Indianapolis and St. Louis; St. Louis, Vandalia, Terre Haute, and Indianapolis; and Logansport, Crawfordsville, and Southwestern. There are numerous large factories, blast furnaces, glass and iron works, machine shops, nail works, &c. Pork packing is extensively carried on. Terre Haute has a handsome court house, a commodious market house and city hall, a good opera house, two orphan asylums, eight fine public school buildings, and several private schools and academies, and is the seat of the state normal school. There are three daily, a tri-weekly (German), and six weekly (one German) newspapers, two public libraries, and 20 churches. Terre Haute was laid out in 1816, and incorporated as a city in 1853.

**TERRELL**, a S. W. county of Georgia, drained by affluents of Flint river; area, about 300 sq. m.; pop. in 1870, 9,053, of whom 5,284 were colored. The surface is nearly level. The Southwestern railroad traverses it. The chief productions in 1870 were 158,130 bushels of Indian corn, 13,973 of oats, 22,898 of sweet potatoes, and 6,163 bales of cotton. There were 444 horses, 983 mules and asses, 982 milch cows, 2,083 other cattle, 1,069 sheep, and 6,742 swine; several manufactories, 6 saw mills, and 1 tannery. Capital, Dawson.

**TERRESTRIAL MAGNETISM.** See MAGNETISM, TERRESTRIAL.

**TERRIER** (*canis terrarius*, Flem.), a small variety of dog, so named from its propensity to pursue and attack its prey in subterranean retreats. It is considered by Hamilton Smith as descended from an indigenous European canine.



Skye Terrier.

There are two well marked varieties, the result of fancy or accident. One, the English or black and tan, is smooth, rounded, elegant in shape, usually black, with tan-colored spots over the eyes and the same tint on the legs and lower parts; the nose is sharp, eyes bright, ears pointed or slightly turned down, and the tail carried high and bowed over the back. The other, the Scotch terrier, the oldest and purest breed, has shaggy and wiry hair, a shorter and fuller muzzle, bearded snout and face, stouter limbs, less elegant form, and a pale sandy or

ochrey color; it is sometimes white. The isle of Skye breed is one of the most prized, and one of the ugliest. The terrier has an acute sense of smell, and is a good attendant on a pack of hounds, forcing foxes and other game from their coverts and dens; it is a determined enemy of the weasel, badger, and rat families. The jaws are very powerful. The Scotch terrier has been known to kill 100 rats in a room in less than seven minutes. In England the terrier blood is visible in most of the sheep and cattle dogs; but the most prized variety is the bull terrier, from a cross with the bulldog, the most determined, pugnacious, and savage of the dog tribe; in this the ears are pointed, and the general characters are those of the bulldog; it is usually white, with some black about the head.—The turnspit is a cross of the terrier with larger and less pure breeds; the body is long and heavy, with disproportionately short and generally crooked legs; it is bold, vigilant, and spirited, and, though larger, is used in Europe for the purposes of the terrier; it is, when best, a cross with a hound; it received its name from its being in old times employed to turn the spit in the kitchen, walking round in a kind of wheel. The *C. vertagus* of the ancients, sometimes erroneously translated turnspit, is the lurcher, a degenerate greyhound.

**TERTIARIANS** (Fr. *tierciare*, from Lat. *tertiarius*, containing a third part), men or women belonging to the "third order" in any one of the monastic orders. The tertiarians, without living in cloistered communities, bind themselves by simple vows to certain prayers and observances of the order. Such an organization of secular persons occurs for the first time in the history of the Premonstratensians, and another was connected with the order of the Templars. But it did not become generally known until Francis of Assisi, after founding the order of the Franciscans (the first order) and the order of the Poor Clares (second order), founded a third one for the numerous laymen who wished to conform themselves to the mode of life of the Franciscans as much as secular occupations would permit. When their number increased, many of them resolved to adopt the common life, and thus the third regular order of Franciscans arose. (See FRANCISCANS, vol. vii., p. 425.) The example of the Franciscans was followed by the Dominicans, Augustinians, Carmelites, Servites, and other orders, all which have connected with them both tertiarians living in the world, and regular tertiarians living in common.

**TERTULLIAN** (QUINTUS SEPTIMIUS FLORENS TERTULLIANUS), one of the early church fathers, born in Carthage about A. D. 150, died between 220 and 240. He was the son of a Roman centurion, became a lawyer, embraced Christianity about 190, and entered the Christian priesthood. He preached at Carthage and probably at Rome, and became widely known by the publication of several controversial treatises, as well as his ascetic practices. About the year 202 he joined the Montanists, and at once became the champion of the sect, with which he remained until his death. The difference between his works written before and those after he became a Montanist seems to be more a difference of spirit than of doctrine; and his writings are classed in authority with those of the other church fathers. He was the fearless champion of Christianity against Jews and pagans, and of catholic orthodoxy in the church. His *Apologeticus* has been called the first plea for religious liberty in Christian literature, and is one of the best defences of Christianity and the Christians against their pagan adversaries. In his treatise "On the Testimony of the Soul" he unfolds the profound thought that Christianity is grounded in the nature of man, and meets its deepest wants. He led the way in ecclesiastical anthropology and soteriology, was the teacher of Cyprian, and the forerunner of Augustine. Among his controversial works are his books "Against the Gentiles," "Against the Jews," "Against Hermogenes" (showing that matter is not eternal, but created by God), "Against the Valentinians," "On the Prescription of Heretics" (asserting vehemently that no doctrine contrary to the received faith had a claim to toleration from the church, or to appeal to the Scriptures, and contradicting the principles of his "Apology"), "Against Marcion," "Against Praxeas," "On the Soul," "On Baptism," "On the Flesh of Christ," and "On the Resurrection of the Body," in all of which he opposes growing errors, and seeks to show what is the true doctrine of the church. Among his practical works belong the book "On Penance;" that "On Prayer," which explains the Lord's prayer; "On Patience;" "To the Martyrs;" "On Theatrical Shows;" "On Idolatry," a casuistical discussion of the degree to which idol worship may be tolerated by Christians; "On the Dress of Women," and on the "Veiling of Virgins," which teach that modesty and the hiding of the features are proper for women in the house of God; and the book "To his Wife," in which he proclaims his aversion to second marriages. His specially Montanist works are the "Exhortation to Chastity" and "On Monogamy," in which he carries to absolute prohibition the theory of the book "To his Wife;" "On Chastity," which denies that those who are guilty of gross sins can be absolved; "On Repentance;" "On Fasting;" "On the Soldier's Crown;" and "On Flight," which insists that Christians ought not to flee from persecutions. Tertullian's works are written in a rude Punic Latin interlarded with African or old Latin idioms and phrases of Latinized Greek. His earlier works are said to have been written in Greek, but have come down only in Latin translations. The style of all is nervous, abrupt, often obscure, and vehement. The first collected edition is that by Beatus Rhenanus (fol., Basel, 1521). Among the numerous later editions are those by Semler (6 vols., Halle, 1770–'73), Leo-

pold in Gersdorf's *Bibliotheca Patrum Latinorum* (vols. iv. to vii., Leipsic, 1839–'41), Migne (vols. i. to iii. of *Patrologie latine*, Paris, 1844), and Oehler (3 vols., Leipsic, 1853). Translations of several, especially of the "Apology," have been published in most of the modern European languages.—The life of Tertullian has been written by Jerome in the early church, and in modern times by Neander (*Antignosticus*, Berlin, 1825) and Hesselberg (Dorpat, 1848). See also the special works on Montanism by Wernsdorf (1751), Münter (1829), Schwegler (1841), and Baur (1851).

**TERUEL. I.** A N. E. province of Spain, in Aragon, bordering on Saragossa, Tarragona, Castellon, Valencia, Cuenca, and Guadalajara; area, 5,494 sq. m.; pop. in 1870, 252,201. The Albarracin mountains traverse it E. and W., sending off numerous spurs on both sides, which are covered with forests and abound in game. Muela de San Juan, one of the principal summits of the main range, is covered with snow during the greater part of the year, and the rivers Tagus, Guadalaviar, and Jucar have their sources on its sides. The province is well watered by the Guadalupe and the Jiloca, affluents of the Ebro, the Guadalaviar, and numerous smaller streams. There are extensive plains producing grain, wine, oil, silk, hemp, flax, saffron, and fruit. Numerous sheep, swine, and cattle are reared. Coarse woollen goods, linen, canvas, leather, paper, and earthenware are manufactured. **II.** A town, capital of the province, on the left bank of the Guadalaviar, 136 m. E. of Madrid; pop. about 10,500. It stands on elevated ground, is surrounded by old walls, and entered by a number of gates surmounted by Aragonese towers. There is a cathedral, episcopal palace, several convents, two hospitals, and a bull ring capable of accommodating 9,000 spectators.

**TESCHEN,** a town of Lower Silesia, Austria, on the right bank of the Olsa, 38 m. S. E. of Troppau; pop. in 1870, including suburbs, 9,779. There is some trade in local products. The principal manufactory is one for yarns, and there is also a large publishing house.—The peace concluded at Teschen, May 13, 1779, between Maria Theresa and Frederick the Great, terminated the war of the Bavarian succession. The former duchy of Teschen comprised till 1849 most of an extensive circle of the same name, now divided into eight bailiwicks.

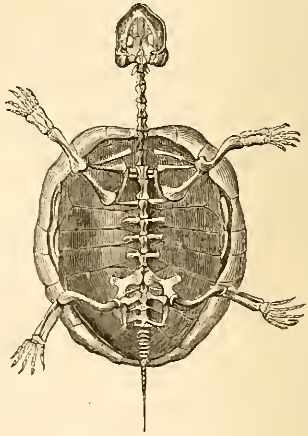
**TESSIN.** See Ticino.

**TESTAMENT.** See Will.

**TESTAMENT, Old and New.** See Bible.

**TESTIMONY.** See Evidence.

**TESTUDINATA,** a term employed by Klein, and adopted by Agassiz, synonymous with chelonians, and embracing the reptiles known as tortoises and turtles. They are the highest of the class, approaching the lower or aquatic birds in form, mode of existence, and in some points of structure; the regions of the body are distinctly marked, and the head has a considerable mobility on the neck. Duméril and Bibron divide the order into four families: *thalassites* or marine turtles; *potamites* or river tortoises; *elodites* or marsh tortoises, with the subfamilies *cryptodères*, which bend the short neck like the letter Z, and conceal the head on the median line beneath the carapace, and *pleurodères*, which curve the long neck horizontally and on the side of the body under the shell; and *chersites* or land tortoises, the highest in rank. Agassiz ("Contributions to the Natural History of the United States of America," vol. i., part 2) adopts Oppel's subdivision of the order, making the suborders: I., *chelonii*, with the families: 1, *chelonioidæ*, marine turtles, and 2, *sphargididæ*, leather or trunk turtles; and II., *amydæ*, with the families: 3, *trionychidæ*, soft-shelled tortoises; 4, *chelyoidæ* (*matamata*); 5, *hydraspididæ*, like *platemys* and other flattened species, mostly South American, united by J. E. Gray to the preceding family; 6, *chelydroidæ*, snapping turtles; 7, *cinosternoidæ*, mud turtles; 8, *emydoidæ*, fresh-water species like the terrapins; and 9, *testudinina*, land tortoises like the great Galápagos, gopher, and common European tortoises. The characters of the suborders with their families will be given under Tortoise and



Skeleton of Tortoise.

Turtle, which may be considered as corresponding to the *amydæ* and *chelonii* of Oppel. The skeleton is in great part external, the bony box being covered only by comparatively thin scales or a naked skin; the most striking character is the stiff vertebral column, spreading in the shape of a carapace or shield, connected by a lateral bridge with the plastron or ventral plate, between which the organs of the trunk are enclosed, and having an anterior and a posterior opening for the protrusion of the head, limbs, and tail, which are all free; locomotion is always performed by the four limbs. The shield consists of a hard and dry epidermic covering, under which is a bony plate made up of the vertebræ, ribs, and sternum, overlaid and the intervals filled with the ossified skin

or dermal skeleton, divided into many pieces united by suture; in the marine turtles this dermal skeleton is imperfect (especially below), less developed in the trionyx, and least of all in the trunk turtle (*sphargis*). The epidermic plates in the tortoise-shell turtle grow only on the anterior edge, the older parts moving backward, much as in the human nail; but in the land tortoises they increase below and on all sides, in concentric rings, like the annual growths of a tree; there is every intermediate stage between these types; a moulting of the epidermis takes place in all chelonians, scale by scale. In all except the imbricated turtle the colors are in the lowest layers of the epidermis; in this they exist in the external dry horny layers, displaying the beautiful and permanent hues of tortoise shell; in the corium or true skin is deposited the phosphate of lime of the dermal skeleton. The skull is solid and compact, and the facial bones are immovably fixed to the cranium; the lower jaw consists of a firm bony arch; the occipital bone strikingly resembles a vertebra; the parietals principally enclose the brain; there are two pairs of frontals, and the nasals are almost always wanting. The cervical vertebræ are nine, if the odontoid process be considered distinct, and have no transverse processes; some have a concave-convex articulation, others a convex-concave, one a biconcave (toward the lower part of the series), and one a biconvex (in the middle), giving considerable freedom of motion in certain directions without the flexibility of the bird's neck. The dorsal vertebræ are 11, of which the first is movable, the rest united into a firm arch by the continuous growth of the spinous processes; the ribs extend from between the vertebræ, being strongest where the dermal skeleton is least developed, as in *trionyx*, *sphargis*, &c.; the sternum consists of four pairs and one odd bone, varying much in size and connection, united to the ribs by a bony bridge, the marginal plates being dermal bones; the caudal vertebræ are very movable, convex behind, concave before, and without spinous processes. The scapular and pelvic arches are withdrawn under the bony roof of the body; the bones of the shoulder are long, straight, and narrow, the scapula and acromion united at right angles, the coracoid running backward among the muscles, and the three united to form the glenoid cavity; the humerus is short, crooked, and turned inward; the forearm and hand have their transverse diameter vertical, the ulna overlying the radius, so that the limb may be drawn back under the carapace by the bending of all the joints in the plane of the scapula; the form of the hand varies in the different families, according as it is used for terrestrial or aquatic locomotion. The pelvic arch is formed by three permanently distinct bones, which meet in the cotyloid cavity; the bones of the hind legs are like those of the anterior, but the femur is straighter than the humerus; there are great differences in the relative size of the two pairs of legs in the two suborders. The cervical muscles are largely developed; the muscles of the limbs are much like those of mammals. The cerebral hemispheres are hollow and larger in proportion than in other reptiles, with a generally smooth surface. There is a tympanic cavity and membrane, the former divided into two parts by a bony partition; the eyes are larger and more movable than in the lower reptiles, similar to those of birds in the lids, nictitating membrane, osseous framework of cornea, and round pupil; a lachrymal gland is present. Hearing and vision are acute, but smell is dull, the nostrils being used chiefly for their slow respiration; they chew their food, and the tongue is broad, thick, and fleshy, with an acute sense of touch; the tongue is of use also in the respiratory process, as they swallow air into the lungs. The upper jaw always shuts over the lower, and both are covered with a peculiar horny sheath; the intestines, as in the higher classes, are longest in the herbivorous families, but the proportions of the different parts vary much without any special reference to the food; the liver and gall bladder are large; spleen and pancreas always present, the former solid and generally attached to the latter, and this to the duodenum; the pancreas is lobular and irregular, and much the largest in the carnivorous feeders; digestion is performed very slowly, and hunger can be endured a long time. Respiration is effected by swallowing air, on account of the immobility of the thoracic cavity, assisted, according to Agassiz, by the diaphragm, which is well developed in the order, and by the scapular and pelvic muscles; the lungs are voluminous, most so in the land tortoises; the trionyx can remain half an hour or more under water, aëration of the blood in this and other aquatic species being doubtless partly effected, as in frogs, through the naked skin; many species have the power of emitting vocal sounds, independent of the sharp hiss which they all produce; respiration is reduced or entirely suspended in the hibernating species, according to the degree of this state. The heart is just above the liver, between its halves; the ventricle is single, divided into two cavities by an imperfect partition, and gives rise both to the two aortæ and the pulmonary artery; it beats about ten times a minute; the lymphatic system is greatly developed, two hearts near the base of the tail sending the lymph over the body. The kidneys are comparatively small, flattened and lobed, in the pelvic cavity, outside the peritoneum; the ureters short, and bladder large; the ovaries are much like those of birds, and the number of eggs matured in a year varies in different members of the order; the cloaca is very large in both sexes. All are oviparous, and the eggs are spherical, covered with a hard shell, and laid in moist or dry ground or hot sand, the number varying from four or five in the land tortoises to more than 100 in the marine turtles; the young, which

appear from the egg in from six weeks to four months or more, are generally very different in form from the parents; there is a hard tubercle on the snout of the young for breaking through the shell of the egg. The growth is very slow, and they attain the period of puberty the latest of all reptiles; they can exist a long time without nourishment, and give signs of vitality, according to Redi's experiments, 23 days after decapitation; the same experimenter ascertained that a land tortoise lived for six months, blindly groping about, after the brain had been entirely removed; they live more than a century.—Chelonians first appeared in the oölitic period, according to Agassiz, when neither genuine birds nor mammals existed; the so-called tortoise footprints in the new red sandstone and Devonian strata were undoubtedly made by crustaceans or other articulates; according to Pictet, impressions of their shields first occur in the Jura limestone and the Stonesfield oölite, and the four types of Duméril and Bibron together; they also are found in the tertiary and diluvial deposits. In the diluvium of the Sivalik hills of the Himalaya range have been found the remains of a gigantic chelonian (*colossochelys atlas*, Cautl. and Falc.), which must have been 18 to 20 ft. in length; it appears that its existence was known to the natives, as this figure enters largely into the old East Indian cosmogonies. In geological times chelonians existed in northern regions of Europe and Asia, now too cold for them; marine and fresh-water species also are often found together, a fact explained by estuary deposits, a more uniform constitution of the early waters of the globe, and a mixture by sudden inundations and surface changes. The present geographical range of chelonians is less extensive than that of the other orders of reptiles, the marine turtles having the greatest and the terrestrial species the least; the marine species are also the largest except the Galápagos tortoise.

**TETANUS**, a spasmodic disease characterized by painful, involuntary, and protracted contraction of a greater or smaller number of the voluntary muscles. As seen in temperate climates, the disease is almost invariably consequent upon a wound or injury; but in particular localities and in hot climates, it may occur without any lesion either external or internal. The disease usually begins with chills and a feeling of depression and debility, with vertigo and sleeplessness. At first there is commonly a feeling of stiffness and uneasiness about the muscles of the neck and jaws. The patient thinks he has taken cold or has a slight rheumatic affection. He finds he is unable to separate the jaws to any distance, and more or less gradually they close, so that he is unable to open the mouth at all; a condition called locked jaw. As the disease advances there is acute pain at the bottom of the stomach, extending through toward the back; and this pain, like the contractions of the voluntary muscles, is aggravated in paroxysms. Gradually the large muscles of the trunk and extremities become affected. In some cases all the muscles are firmly contracted, and the body remains stiff and straight. Ordinarily the strong extensors of the trunk and limbs are more affected than the flexor muscles, or their superior power overcomes the resistance of these latter, and during the paroxysm the body is forcibly curved backward, the patient resting upon his hands and heels only. This constitutes *opisthotonos*. Occasionally, though it must be very rarely, the body is bent forward, constituting *emprosthotonos;* and still more rarely there is lateral curvature, forming *pleurosthotonos*. The muscles concerned in deglutition are early affected, so that swallowing is rendered difficult or impossible. Later, spasms of the muscles of the face occur, the brow becoming knit, the eyes wide open, fixed and staring, the nostrils distended, and the angles of the mouth drawn back, exposing the clenched teeth, and producing an expression called *risus sardonicus*. When the disease has once set in, the muscles affected are rarely at any time afterward wholly relaxed. At intervals more or less closely approximated to each other according to the severity of the disease, paroxysms occur during which the spasm is aggravated, the muscles affected becoming tense and hard as boards. During these paroxysms the patient commonly suffers from intense pain in the muscles affected, and the substernal pain, dependent probably on spasm of the diaphragm, is likewise aggravated. Cases have occurred in which the teeth have been broken, bones fractured, or muscles torn across. The spasms come on even when the patient is perfectly at rest; but they are evidently excited by the slightest attempt at voluntary motion, by efforts at deglutition, or by mental emotion. The patient's mind is commonly unaffected throughout the disease; the bowels are apt to be obstinately constipated, and when evacuations are obtained they are offensive and unnatural. Death may occur either suddenly during a paroxysm or from suffocation, the muscles of respiration becoming fixed and the spasm in some instances probably affecting the glottis. In other cases death results from exhaustion, the patient being worn out by pain, sleeplessness, and want of nourishment.—Tetanus is fatal in the large majority of cases. Post-mortem examination throws but little light on its pathology. Dr. Lockhart Clark believes that degeneration of the cells of the spinal cord is always present; but the fact that the symptoms are so similar to those of poisoning by strychnia would lead to the opinion that the cause of the disease is in a morbid condition of the blood, although the medulla oblongata and spinal cord are the parts attacked. In cases arising from wounds, the nerve leading from the wound shows evidences of inflammation, being commonly red and swollen; but with this exception no lesions have been

found which are constantly connected with the disease.—Idiopathic tetanus, rare in temperate, is not uncommon in hot climates; but though heat acts as a predisposing cause, the exciting cause is generally exposure to damp and cold. In traumatic tetanus, exposure to cold, particularly when the body is debilitated by previous warm weather, seems to be an efficient cause. Thus the wounded in the battle of Dresden, who were exposed to cold and wet just after the battle, while the previous weather had been hot and oppressive, suffered severely from tetanus; and after the battle of Bautzen, where the wounded lay on the field exposed to cold and rain during the night, Larrey found more than 100 attacked with tetanus the next morning. Tetanus is more liable to follow punctured and lacerated than incised wounds; and wounds of the palmar surface of the feet and hands, which are abundantly supplied with nerves, are particularly dangerous, but it may follow wounds of every character. Even those made by the knife of the surgeon and the stroke of a whip, the cutting of a corn and extraction of a tooth, have all been followed by this formidable and fatal disease. Cases are on record in which lying-in women have been seized by the disease. The time which elapses between the reception of the injury and the period of invasion of the disease varies greatly. Larrey says that during the campaign in Egypt it rarely appeared before the fifth or after the fifteenth day; yet some cases are on record in which it came on in a few hours, and others in which it was delayed for more than a month. When the paroxysms come on suddenly, recur at short intervals, and increase in violence, treatment is rarely of any avail; death in such cases occurs often as early as the second, and is rarely delayed beyond the fifth day. When the attack is less violent and the interval between the paroxysms longer, the prospects of the patient are better, and if life is protracted beyond the tenth day he will frequently recover.—The treatment of tetanus is unsatisfactory. The inhalation of chloroform has been strongly recommended, and where it is well borne, it mitigates greatly the sufferings of the patient. Opium has been given in large and repeated doses; when recourse is had to it, it should be administered in a liquid form, or some salt of morphia should be used. A strong solution of the sulphate of morphia may be given by subcutaneous injection. Wine and distilled spirits, with or without opium, have been given in large quantities, and in many cases apparently with benefit. The bowels should be occasionally moved by active purgatives. But as the paroxysms are mainly excited by external sources of irritation, even slight ones, the principle of the treatment should be to keep the patient perfectly quiet. Stillness, a darkened apartment, few attendants, and the absence as far as possible of all causes of physical or mental disturbance, promise a better chance of recovery than any active interference or the repeated administration of medicinal agents.

**TETUAN**, a city and seaport of Morocco, in the province of Fez, at the W. end of the Mediterranean, 21 m. S. by W. of Ceuta; lat. 35° 37′ N., lon. 5° 18′ W.; pop. about 20,000. The town is about 6 m. W. of the coast, on high ground, which rises on the south into a ridge 3,000 ft. high. It is surrounded by a wall flanked with towers, and is defended by a castle. The streets are narrow and dirty, but there are some fine buildings, particularly mosques, of which there are 40. Its harbor is an open roadstead unprotected on the east, and is fit for small vessels only. The town has manufactures of leather, leather goods, swords, and firearms, and a considerable inland trade through Fez. Its foreign trade consists principally in supplying Gibraltar with provisions. In 1873, 211 vessels, of 2,716 tons, entered its port. The value of its imports was $111,555; exports, $55,775. Tetuan was captured by the Spaniards in 1860, but was given up in the following year.

**TETZEL**, or **Tezel, Johann**, a German monk, born in Leipsic about 1460, died there in August, 1519. He studied theology and philosophy at the university of Leipsic, and in 1489 entered the order of Dominicans. He gained celebrity as a popular preacher, and was repeatedly engaged to preach indulgences granted by the pope to raise money for religious purposes. The early Protestant biographers of Tetzel say that he sold certificates of indulgence without requiring previous confession, and indulgences for future sins; that he led a very immoral life, and was even convicted at Innspruck of adultery; but Catholic historians have generally qualified these statements as gross exaggerations, though they admit that he often offered the indulgences in an offensive and mountebank way. In 1516 Tetzel began the publication of an indulgence designed to procure means for the construction of St. Peter's at Rome, receiving at the same time an appointment as inquisitor. Never before had the preaching of an indulgence produced such a commotion. He is said to have assured the people that as soon as the money resounded in the chest their sins would be forgiven, and the souls of the departed received into heaven; but Catholics maintain that this is conclusively refuted by the *Instructio Summaria Sacerdotum ad Prædicandas Indulgentias*, prepared by Tetzel in 1517, in which he makes the gaining of an indulgence expressly dependent upon repentance and confession. As a delegate of the highest ecclesiastical authorities, Tetzel was generally received with great pomp, but at the same time met with a powerful and rapidly increasing opposition. On Oct. 31, 1517, Luther posted the celebrated 95 theses against the abuses in preaching indulgences on the doors of the church in Wittenberg. Tetzel publicly burned the theses at Jüterbogk, and in January, 1518,

in a public disputation at the university of Frankfort-on-the-Oder, defended several antitheses. The students of Wittenberg, in their turn, burned 800 copies of the antitheses of Tetzel. Tetzel replied once more, in May, by a refutation of the sermon of Luther on indulgences and grace, but seems to have had no longer any influence on public opinion. Among the latest biographers of Tetzel are Hoffmann, a Protestant (*Lebensbeschreibung von Tetzel*, Leipsic, 1844), and Gröne, a Roman Catholic (*Tetzel und Luther, oder Lebensgeschichte und Rechtfertigung des Ablasspredigers und Inquisitors Dr. Johann Tetzel*, &c., Soest, 1853).

**TEUCER** (Gr. Τεῦκρος). **I.** The first king of Troy, son of the river god Scamander by the nymph Idæa, after whom the Trojans are sometimes called Teucrians. **II.** A Grecian hero in the war against Troy, the son of Telamon, king of Salamis, and Hesione of Crete, and a half brother of Ajax. He was the best archer among the Greeks; but on his return from Troy his father refused to receive him in Salamis because he had not avenged the death of Ajax nor brought back his body. He therefore settled in the island of Cyprus, and founded there the city of Salamis.

**TEUFFEL, Wilhelm Sigismund,** a German philologist, born in Ludwigsburg, Sept. 27, 1820, died March 8, 1878. He studied at the university of Tübingen, devoted himself to the critical study of Horace, and published valuable papers on the works and times of that author. In 1845 he became editor of the *Realencyklopädie der classischen Alterthumswissenschaft*, begun by Pauly. In 1849 he was appointed professor of classical philology in Tübingen. He especially studied the literary history of Greece and Rome, and also of Germany, and his various publications on single authors, as Juvenal, Aristophanes, and Æschylus, were universally received as important. His principal work, *Geschichte der römischen Literatur* (2 vols., Leipsic, 1868–'70), has been translated into several languages (London, 1874).

**TEUTOBURG FOREST,** a mountain chain of Germany, partly in the principality of Lippe, partly in Prussia, extending, at first under the name of Egge, in a N. direction through the territory of Paderborn to Driburg, then N. W. toward Bielefeld and Halle, and terminating at the Bervergern, 5 m. E. of Rheine on the Ems. Its total extent is about 80 m. It reaches its highest point of more than 1,500 ft. near Horn in Lippe. According to Tacitus, the Roman legions of Varus were defeated (A. D. 9) in this mountain region, which he calls *Teutoburgiensis saltus*, by Arminius, prince of the Cherusci, whose memory is celebrated as that of the liberator of Germany. (See ARMINIUS.) His colossal monument by Bandel was unveiled by the emperor of Germany, Aug. 16, 1875, amid national rejoicings, on the summit of the Grotenberg near Detmold. (See BANDEL.)

**TEUTONIC KNIGHTS,** or **Knights of the Hospital of St. Mary in Jerusalem,** a powerful religious and military order which originated during the crusades. The hospital of St. Mary in Jerusalem, from which the order derives its canonical name, was founded soon after the capture of Jerusalem by the crusaders in 1099. A German merchant and his wife threw open their dwelling to the poor and sick of their own nation; a chapel was afterward attached to the house by permission of the patriarch and dedicated to St. Mary. The establishment, to which the founder devoted all his wealth, was after its extension maintained by alms collected among the Germans; and a number of distinguished persons also devoted their property and services to the same purpose, assuming a religious dress and binding themselves by monastic vows (1119), with the approbation of Pope Calixtus II. During the siege of Acre in 1189 charitable burghers of Bremen and Lübeck established a guild of hospitallers for German soldiers, whose numbers were so great after the death of Frederick Barbarossa that the merchants made tents with the sails of their vessels, and called to their assistance the brethren of St. Mary in Jerusalem. Both confraternities were then organized into one order by Duke Frederick of Swabia, who obtained the approbation of Pope Celestine III., Feb. 23, 1192. The new order retained the rule of St. Augustine adopted by the German brotherhood in Jerusalem. None were at first admitted to membership but Germans of noble birth; about 1221 half-knights or sergeants, as among the templars and hospitallers, were added, as well as priest-chaplains. The dress was black with a white mantle, upon which was a black cross with a silver edging. The order had an elective grand master, who first dwelt at Jerusalem, then when Palestine fell into the hands of the Turks at Venice, and at the close of the 13th century at Marburg. Conrad, duke of Masovia, called the Teutonic knights, then under the famous grand master Hermann of Salza, to his assistance about 1226, to repel the incursions of the heathen Prussians and Lithuanians, and to help in spreading the gospel among them. He gave them the territory of Culm on the Vistula, and from this point they extended their conquests over the territory of Prussia, and with the aid of the knights sword-bearers over Courland and Livonia, exterminating the pagan inhabitants with fire and sword. In 1309 the grand master fixed his seat at Marienburg. Possessing the richest and most commercial provinces of the north, the order became exceedingly powerful; and at the beginning of the 15th century, when it had reached its greatest prosperity, its territory extended from the Oder to the gulf of Finland, and its yearly revenue was estimated at 800,000 marks. Nobles from all parts of Europe flocked to its banner. Internal dissensions, luxury, and unjust and oppressive acts threatened its decline from this period, and a conflict with the Polish kings hastened it. In the

battle of Grünwald or Tannenberg in 1410 they were totally defeated by Ladislas Jagellon; and after a subsequent long war with Casimir IV., West Prussia was given up to Poland, and for East Prussia they were compelled to do homage (1466). An attempt to regain their independence deprived them of East Prussia, which in 1525 was presented by Sigismund I. of Poland to the grand master, the margrave Albert of Brandenburg, as a hereditary duchy. The order was now reduced to a mere shadow of its former greatness. In 1527 the grand master fixed his seat at Mergentheim in Swabia, became a spiritual prince of the German empire, and had under him 11 provinces divided into commanderies. In 1805 the peace of Presburg gave to the emperor of Austria the rights, revenues, and possessions of grand master of the Teutonic order; but in the campaign of 1809 Napoleon while at Ratisbon abolished the order on April 24, its widely scattered territory, comprising about 850 sq. m. with 88,000 inhabitants, falling to the princes in whose dominions it was. It was revived in the Austrian empire in 1834 and placed under the protection of the imperial family; it was more fully reorganized in 1840. From 1863 till his death in Mexico, the archduke Maximilian was grand master. The present grand master is the archduke Wilhelm.

**TEUTONS** (Lat. *Teutones* or *Teutoni*), a powerful people of ancient Germany, who probably dwelt on the southern shores of the Baltic, in the vicinity of the Cimbri, together with whom they invaded the dominions of the Roman republic at the close of the 2d century B. C., when they were annihilated by Marius. (See CIMBRI.) The name Teutons is also applied to the ancient Germans in general. (See GERMANIC RACES AND LANGUAGES.)

**TEWKESBURY**, a market town of Gloucestershire, England, at the confluence of the Avon and Severn, 108 m. W. by N. of London; pop. in 1871, 5,409. It has an old church in the Norman style, town hall, mechanics' library, and stocking, lace, and nail manufactories. Edward IV. here defeated the Lancastrians in 1471.

**TEXAS**, a S. W. state of the American Union, the 15th admitted under the constitution, situated between lat. 25° 50′ and 36° 30′ N., and lon. 93° 30′ and 106° 40′ W.; greatest length, from the mouth of the Rio Grande to the N. W. corner, about 825 m.; greatest breadth, along the 32d parallel, about 740 m.; area, 274,356 sq. m., being greater than that of any other state or territory except Alaska, and nearly six times as great as that of New York. It is bounded N. by New Mexico (W. of the 103d meridian), the Indian territory, and Arkansas, the Red river being the dividing line E. of the 100th meridian; E. by the Indian territory (N. of lat. 34° 30′), Arkansas, and Louisiana, from the last of which it is mostly separated by the Sabine river and lake; S. E. by the gulf of Mexico; S. W. by Mexico, from which it is separated by the Rio Grande; and W. by New Mexico. The state is (1876) divided into 174 counties, of which 26, marked with an *, are unorganized, viz.: Anderson, Angelina, Aransas, Archer,* Atascosa, Austin, Bandera, Bastrop, Baylor,* Bee, Bell, Bexar, Blanco, Bosque, Bowie, Brazoria, Brazos, Brown, Burleson, Burnet, Caldwell, Calhoun, Callahan,* Cameron, Camp, Cass, Chambers, Cherokee, Clay, Coleman, Collin, Colorado, Comal, Comanche, Concho, Cooke, Coryell, Crockett,* Dallas, Dawson,* Delta, Denton, De Witt, Dimmitt,* Duval,* Eastland, Edwards,* Ellis, El Paso, Encinal,* Erath, Falls, Fannin, Fayette, Fort Bend, Franklin, Freestone, Frio, Galveston, Gillespie, Goliad, Gonzales, Grayson, Greer* (see GREER), Gregg, Grimes, Guadalupe, Hamilton, Hardeman,* Hardin, Harris, Harrison, Haskell,* Hays, Henderson, Hidalgo, Hill, Hood, Hopkins, Houston, Hunt, Jack, Jackson, Jasper, Jefferson, Johnson, Jones,* Karnes, Kaufman, Kendall, Kerr, Kimble,* Kinney, Knox,* Lamar, Lampasas,

State Seal of Texas.

La Salle,* Lavaca, Lee, Leon, Liberty, Limestone, Live Oak, Llano, McCulloch,* McLennan, McMullen,* Madison, Marion, Mason, Matagorda, Maverick, Medina, Menard, Milam, Montague, Montgomery, Morris, Nacogdoches, Navarro, Newton, Nueces, Orange, Palo Pinto, Panola, Parker, Pecos, Polk, Presidio, Rains, Red River, Refugio, Robertson, Rockwall, Runnels,* Rusk, Sabine, San Augustine, San Jacinto, San Patricio, San Saba, Shackleford, Shelby, Smith, Somerville, Starr, Stephens,* Tarrant, Taylor,* Throckmorton,* Titus, Tom Green, Travis, Trinity, Tyler, Upshur, Uvalde, Van Zandt, Victoria, Walker, Waller, Washington, Webb, Wegefarth,* Wharton, Wichita,* Wilbarger,* Williamson, Wilson, Wise, Wood, Young, Zapata, Zavala.* An extensive region in the W. part of the state N. of the 32d parallel is not divided into counties, the N. portion being known as Bexar territory and the S. portion as Young territory. The principal cities are Galveston (pop. in 1870, 13,818), San Antonio (12,256), Houston (9,382), Brownsville (4,905), Austin (the capital, 4,428), and Jeffer-

son (4,190). Other important places are Bastrop, Bonham, Brazoria, Bremond, Brenham, Columbus, Corpus Christi, Dallas, Eagle Pass, Fairfield, Fredericksburg, Gonzales, Henderson, Huntsville, Independence, Indianola, La Grange, Laredo, Lavaca, Marshall, Nacogdoches, Navasota, New Braunfels, Richmond, San Marcos, Seguin, Sherman, Sulphur Springs, Victoria, Waco, and Waxahachie. The population of Texas in 1806 has been estimated at 7,000; in 1834, at 21,000; in 1836, at 38,500; and in 1845, at 150,000. The results of the three federal censuses are as follows:

| YEARS. | Whites. | Free colored. | Slaves. | Total. | Gain per cent. | Rank. |
|---|---|---|---|---|---|---|
| 1850 ... | 154,034 | 397 | 58,161 | 212,592 | ...... | 25 |
| 1860 ... | 420,891 | 355 | 182,566 | 604,215 | 184·20 | 23 |
| 1870 ... | 564,700 | 253,475 | ...... | 818,579 | 35·48 | 19 |

The total for 1860 includes 403 Indians, and that for 1870 379 Indians and 25 Chinese. There are very few inhabitants W. of the 100th meridian, except along the Rio Grande. In the vicinity of San Antonio there is a large population of German origin. Of the total population in 1870, 423,557 were males and 395,022 females, 756,168 native and 62,411 foreign born. Of the natives, 388,510 were born in the state, 62,224 in Alabama, 51,435 in Tennessee, 42,537 in Mississippi, 41,206 in Georgia, 27,290 in Louisiana, 23,357 in Arkansas, 22,165 in Virginia and West Virginia, 18,655 in North Carolina, 18,419 in Missouri, 17,813 in Kentucky, 17,717 in South Carolina, 5,854 in Illinois, 2,873 in New York, 2,783 in Indiana, 2,385 in Maryland, 2,052 in Ohio, 1,934 in Florida, and 1,877 in Pennsylvania. Of the foreigners, 23,985 were natives of Germany, 23,020 of Mexico, 6,762 of the British isles (including 2,037 English and 4,031 Irish), 2,232 of France, and 1,748 of Austria (proper). Of the colored population, 225,658 were blacks and 27,817 mulattoes. There were 145,184 males and 139,667 females between 5 and 18 years of age, 158,765 males from 18 to 45, and 184,094 males 21 and upward, of whom 169,258 were citizens of the United States and 14,736 unnaturalized foreigners. The number of families was 154,483, with an average of 5·3 persons to each; of dwellings, 141,685, with an average of 5·78 to each. Of persons 10 years old and upward, 189,423 could not read, and 221,703 could not write; of the latter 203,334 were natives and 18,369 foreigners, 110,562 males and 111,141 females, 70,895 whites, 150,617 colored, and 191 Indians; 47,636 were between 10 and 15 years of age, 41,768 between 15 and 21, and 132,299 21 and upward, of whom 64,819 were males. There were 404 blind persons, 232 deaf and dumb, 270 insane, and 451 idiotic. Of the 237,126 persons 10 years old and upward returned as engaged in all occupations, there were employed in agriculture 166,753, including 81,123 agricultural laborers, 79,015 farmers and planters, 3,338 stock raisers, and 2,049 stock herders; in professional and personal services, 40,882, including 831 clergymen, 13,692 domestic servants, 14,371 laborers, 1,027 lawyers, 1,906 physicians and surgeons, and 1,709 teachers; in trade and transportation, 13,612; and in manufactures and mining, 15,879.—Texas may be divided into four sections, eastern, central or middle, western, and northern Texas. Eastern Texas embraces the territory between the Sabine and Trinity rivers, and is the great timber region of the state, there being only a few prairies confined to the gulf coast. The southern portion is low and level, the northern rolling and elevated, but not mountainous. The greater portion of central Texas, between the Trinity and Colorado rivers, is prairie, but there is considerable timber along the streams. Northern Texas, including two or three tiers of counties from Red river, is about equally divided between prairie and forest. Western Texas embraces the region between the Colorado and Rio Grande rivers. Prairies cover about four fifths of its surface; with the exception of occasional districts covered with post oak or the mezquite tree, timber is confined almost entirely to the valleys of the streams, which are densely wooded. The N. W. extremity of the state, between Indian territory and New Mexico, is known as the "panhandle." In general, the S. and S. E. portion, along the coast, is level and of little elevation; N. of this the country is undulating; the W. and N. W. region is mostly an elevated table land; while the district between the Pecos and Rio Grande is mountainous. The table land includes a large portion of the Llano Estacado, and has been but imperfectly explored; it is said to vary from 2,000 to 4,000 ft. in height. The Llano Estacado or Staked Plain (so named from the great abundance of yucca stems, resembling stakes) extends from the Rio Pecos in New Mexico on the west to the head waters of the Colorado, Brazos, and Red rivers on the east, and from the valley of the Canadian on the north to the Pecos on the south. Its surface is gently undulating; vegetation is scanty, owing to the dryness of the climate and the lack of streams. The principal ranges between the Pecos and Rio Grande are the Guadalupe, Sierra Hueca, Eagle, Sierra Blanca, and Apache mountains, attaining in places an elevation of between 5,000 and 6,000 ft. Between the upper waters of the Colorado and Brazos is a large tract of timbered land known as the "mezquite timber," and between the upper Brazos and Trinity a long tract from 5 to 30 m. in width, extending from Johnson co. to the Canadian river in Indian territory, and called the Cross Timbers. —The coast of Texas, which extends along the gulf of Mexico about 400 m., is bordered with a chain of low sand islands, between which and the mainland lie a series of bays, sounds, and lagoons; the most important of these, beginning at the northeast, are Galveston, Matagor-

da, Espiritu Santo, Aransas, and Corpus Christi bays, and the Laguna del Madre. Galveston bay is the largest, and has the best entrance, its inlet having 13 ft. of water, while in good anchorage just outside there is 24 ft.; it extends inland from the gulf of Mexico 35 m. Matagorda bay, nearly 60 m. long by 6 to 10 m. wide, and Laguna del Madre, nearly 100 m. long by 3 to 6 m. wide, are properly sounds, and run parallel with the shore. The entrance of Matagorda bay, which is rapidly filling up, has only 7 ft. of water; and San Luis inlet, the entrance to West bay, a sound connecting with Galveston bay, has but 6 ft. Aransas bay is 25 m. long from N. E. to S. W. and about 10 m. wide, and Copano bay, a sound opening into it, is 20 m. long by 3 m. wide; Corpus Christi bay is 20 m. long by 15 m. wide, and Espiritu Santo 20 by 10 m. The entrance to all these is much obstructed by the bars at the inlets.—E. of the 100th meridian the state is generally well watered. The Rio Grande forms the boundary with Mexico, and is navigable for 400 or 500 m. The Rio Pecos, its principal tributary, entering from New Mexico, flows S. E. through the W. extremity of the state. The most important rivers, proceeding N. E. along the coast from the mouth of the Rio Grande, are: the Nueces, emptying into Corpus Christi bay; the San Antonio and Guadalupe, into Espiritu Santo bay; the Lavaca, into Lavaca bay and thence into Matagorda bay; the Colorado, into Matagorda bay; the Brazos, into the gulf of Mexico; the San Jacinto and Trinity, into Galveston bay; and the Neches and Sabine, into Sabine lake, which discharges into the gulf of Mexico through Sabine pass. The Sabine rises in the N. E. part of Texas, flows S. E. to the Louisiana border (about lat. 32°), and thence S., separating the two states. It is navigable in some portions by small craft. The Neches and its chief tributary, the Angelina, are navigable for about 200 m. from Sabine lake. The Trinity rises in the N. part of the state near the Red river, and flows S. S. E.; it is navigable for about 250 m. The Brazos, Colorado, Guadalupe, San Antonio, and Nueces rivers are during most of the year navigable but a short distance, though susceptible of improvement. The chief tributary of the Nueces is the Rio Frio. The Colorado and Brazos rise on the E. edge of the Llano Estacado, and flow S. E. across the state. The chief tributaries of the former are the Concho, San Saba, and Llano from the west; of the latter, the Little river from the west and the Navasota from the east. The N. E. corner of the state is watered by the Sulphur fork of Red river, which joins the main stream in Arkansas. A little S. of this are Big and Little Cypress bayous, which discharge through lakes into Red river in Louisiana. Red river rises by several forks in the N. W. part of the state, flows E., and after crossing the 100th meridian separates Texas from Indian territory and Arkansas, and enters the latter state. It is navigable for nearly its whole course on the boundary, though obstructed somewhat by shifting sands for a part of the distance. Its largest Texan tributary is the Big Wichita, entering near lon. 98°. The N. extremity of the state is crossed by Canadian river, running E. from New Mexico into Indian territory.—The principal geological formations are the alluvial, tertiary, cretaceous, and carboniferous. The alluvial extends along the gulf coast; back of this is the tertiary, having its widest expansion in the east, where it reaches Red river in Lamar co.; N. W. of the tertiary is the cretaceous, extending W. on Red river to Cooke co. and S. to San Antonio, and probably forming the table lands and plains of the west and southwest. The carboniferous formation extends through the counties W. of Cooke to the Staked Plain, stretching S. from Red river to and beyond the upper Colorado. Coal beds have been discovered here, but scarcely anything has been done to test the quality or quantity of the mineral. Coal has also been found at various points in the tertiary, particularly in Bastrop co., W. of the Colorado; in Milam, Robertson, Leon, and Limestone cos., near the Brazos and Trinity; and in Anderson and Rusk cos., in eastern Texas. The tertiary coal has to some extent been proved valuable for fuel. Iron ores are abundant in the tertiary in eastern and central Texas; they also occur in the N. W. part of Grayson co., on Red river, and in the upper Cross Timbers; in Burnet and Llano cos., N. W. of Austin; and also, it is said, in Stephens co., further N. They were worked during the civil war in Cherokee and Nacogdoches cos., in eastern Texas, and in Bowie and other counties in the N. E. corner of the state. Copper ore occurs in the carboniferous formation, particularly in the N. part. Lead has been found in connection with silver in western Texas; steatite or soapstone in Llano co.; and marble of various colors and fair quality in Burnet, Llano, and San Saba cos. In the N. W. part of the state, about the head waters of Red river, is an extensive gypsum region. There are salt wells in Van Zandt co., in the northeast, in Young and Wise cos., in the northwest, and in Lampasas and Llano cos., on the Colorado. Salt beds are reported in the gypsum region and on the Rio Pecos. Between Corpus Christi and Brownsville are many shallow lagoons or arms of the gulf, which during the prevalence of winds blowing inland are filled with salt water. This is evaporated, depositing the salt, which is collected upon the subsidence of the water. Chalybeate springs are common in the iron districts of the tertiary. At Lampasas in the county of the same name are fine sulphur springs, which also exist in Grimes, Rusk, and Hopkins cos., in the E. part of the state.—The climate is remarkably salubrious, and though warm enough for the production of most of the semi-tropical and some of the tropical

fruits, it is less enervating and more free from malarious diseases than that of any other of the gulf states. Northers, cool, dry winds, occur from October to May at intervals of about a week, rarely lasting more than three days. They produce a sudden depression in the temperature, but are said to make the climate more healthful and the air purer. The heat of summer is tempered by winds from the gulf, which blow far inland. The mean annual temperature in the southwest, near the mouth of the Rio Grande, is 72°; about the parallel of Austin, 68°; thence N. it gradually diminishes to 60° along the Red river. The highlands in the west are cooler, and in the extreme northwest the mean annual temperature is not more than 56°. The thermometer seldom falls below 25° in winter or rises above 95° in summer. The E. and S. portions have the most rain; as we proceed N. W. from the gulf, the moisture diminishes. The average annual rainfall in the northeast is 48 in., decreasing to 24 in. in the southwest near the gulf. In the extreme northwest it is only 16 in., and at some points between the Pecos and Rio Grande not more than 8 in. The following are the results of observations for 17 years (1858 to 1874 inclusive) at Austin (lat. 30° 15′, lon. 97° 47′): mean annual temperature, 67·61°, varying from 65·82° in 1869 to 68·92° in 1862; mean temperature of the hottest month (July), 84°; of the coldest month (January), 50°; minimum observed, 6°; maximum observed, 106°; average annual rainfall, 34·54 in., varying from 23·17 in 1862 to 48·79 in 1874. The most rain fell in September (average 4·96 in.) and the least in December (average 1·93 in.). Corn planting usually begins about the middle of February, and grain is harvested in the latter part of May, and Indian corn in July. Cotton picking begins about July 10, and continues to Dec. 1. The number of deaths, according to the census of 1870, was 11,197, of which there were from general diseases 3,848, including 680 from consumption, 464 from enteric fever, 596 from intermittent fever, and 327 from remittent fever; from diseases of the nervous system, 1,430; of the circulatory system, 204; of the respiratory system, 1,979, including 1,499 from pneumonia; of the digestive system, 1,498.—The soil of Texas is in general very fertile. The river bottoms are unsurpassed in this respect by those of any state of the Union. There are three or four varieties of soil, each well adapted to certain crops. The stiff black soil of the river bottoms is fittest for sugar and cotton, though the latter grows well on the prairies and uplands; the finer black or chocolate-colored soil of the prairie lands yields abundant crops of corn and the cereals, and the lighter copper-colored soil of the uplands is admirable for the grasses and fruits; while the fine silt of the islands produces the best sea island cotton known. The soil of the desert tracts of the northwest is sandy and charged with carbonate of soda and other alkalies; but even this, wherever it can be irrigated, produces grass and herbage moderately. Irrigation has been successfully practised in some instances in the west, where rain is scanty. In 1875 an act was passed granting land in aid of companies organized for constructing canals for irrigation and navigation. Texas is especially noted as a stock-raising country, for which the mildness of its climate and the great variety of its nutritious grasses peculiarly fit it. The W. portion, even where too dry for agriculture, is particularly adapted to cattle and sheep, and here are vast herds and flocks. Large numbers of horses and hogs are also kept. The buffalo and deer are found in the northwest, and wild horses or "mustangs" roam over the W. prairies. The other wild animals and the birds are similar to those of other portions of the Union. Among the more important grasses are the mezquite grasses of the west, which afford excellent pasturage at all seasons. The principal forest trees, of some of which several species occur, are the oak, elm, maple, hickory, pecan, sycamore or buttonwood, magnolia, willow, pine, cypress, mulberry, cedar, sweet gum, ash, walnut, palmetto, cottonwood, Osage orange, and mezquite. Eastern Texas is an extensive pine region. The principal species in the north is the short-leafed pine (*pinus mitis*), and in the south the long-leafed (*P. palustris*); the latter is valuable for timber and turpentine. The soil of the pine lands, though sandy, is productive. The cypress occurs in swamps and on the river banks in various parts of the state, and attains a great size. The live oak extends N. through central and western Texas to the Red river. The Osage orange is especially valuable for hedges, and in northern Texas attains a large size. The mezquite is one of the indigenous trees of Texas, growing in the west, valuable for fuel and for various other uses. (See Mezquite.) Numerous species of cactus are abundant W. of the Nueces river. Peaches do well in a large portion of the state, and apples thrive in the north. Pears, blackberries, and strawberries are also raised. Seven species of grapes are indigenous. In the south figs and oranges may be produced. The chief crops are cotton, Indian corn, and wheat. Cotton and corn may be grown in nearly every part of the state. Wheat is raised chiefly in the north. The sugar cane is cultivated principally on the Brazos near its mouth, and rice in the S. E. corner of the state. Oats, barley, beans, tobacco, and sweet and Irish potatoes are also raised to some extent.—The number of acres of land in farms according to the census of 1870 was 18,396,523, of which 2,964,836 were improved; number of farms, 61,125, of which 717 contained under 3 acres each, 4,659 from 3 to 10, 13,594 from 10 to 20, 24,620 from 20 to 50, 10,890 from 50 to 100, 6,268 from 100 to 500, 305 from 500 to 1,000, and 72 more than 1,000; cash value of farms, $60,149,950; of farming implements

and machinery, $3,396,793; amount of wages paid during year, including value of board, $4,777,638; estimated value of all farm productions, including betterments and additions to stock, $49,185,170; value of orchard products, $69,172; of produce of market gardens, $74,924; of forest products, $66,841; of home manufactures, $293,308; of animals slaughtered or sold for slaughter, $4,835,284; of all live stock, $37,425,194. The productions were 66,173 bushels of spring wheat, 348,939 of winter wheat, 20,554,538 of Indian corn, 762,663 of oats, 44,351 of barley, 28,521 of rye, 44 of buckwheat, 42,654 of peas and beans, 208,383 of Irish potatoes, 2,188,041 of sweet potatoes, 7 of clover seed, 497 of grass seed, 2 of flax seed, 63,844 lbs. of rice, 59,706 of tobacco, 1,251,328 of wool, 3,712,747 of butter, 34,342 of cheese, 51 of hops, 25 of flax, 13,255 of wax, 275,169 of honey, 6,216 gallons of wine, 5,032 of maple molasses, 174,509 of sorghum molasses, 246,062 of cane molasses, 2,020 hogsheads of cane sugar, 5 tons of hemp, 18,982 of hay, and 350,628 bales of cotton. There were on farms 424,504 horses, 61,322 mules and asses, 428,048 milch cows, 132,407 working oxen, 2,933,588 other cattle, 714,351 sheep, and 1,202,445 swine; besides which there were 150,137 horses and 496,115 neat cattle not on farms. The number of cattle was greater than in any other state. In 1873 718,247 horses and mules, 3,175,682 cattle, and 1,476,844 sheep were returned by the assessors.—There were 2,399 manufacturing establishments in 1870, having 540 steam engines of 11,214 horse power, and 116 water wheels of 1,830 horse power; hands employed, 7,927; capital invested, $5,284,110; wages paid, $1,787,835; value of materials used, $6,273,193; of products, $11,517,302. The particulars of the principal branches are as follows:

| INDUSTRIES. | Establishments. | Hands employed. | Capital. | Value of products. |
|---|---|---|---|---|
| Agricultural implements.... | 12 | 44 | $12,550 | $42,120 |
| Blacksmithing .............. | 380 | 761 | 177,285 | 534,550 |

—Texas is divided into five customs districts: Brazos de Santiago (port of entry, Brownsville), Corpus Christi (the same), Paso del Norte (El Paso), Saluria (Indianola), and Texas (Galveston). The chief item of export is cotton. The trade with Mexico is important. There are no returns of the trade with other portions of the Union. The following table contains details of the foreign commerce for the year ending June 30, 1875:

| DISTRICTS. | Imports. | Exports of domestic products. | Exports of foreign products. | ENTRANCES. | | CLEARANCES. | |
|---|---|---|---|---|---|---|---|
| | | | | No. | Tons. | No. | Tons. |
| Brazos de Santiago........................ | $2,002,748 | $833,312 | $997,658 | 49 | 30,984 | 41 | 20,956 |
| Corpus Christi.......................... | 322,803 | 205,557 | 243,966 | 8 | 5,142 | 9 | 5,930 |
| Paso del Norte........................ | 308,991 | 40,323 | ........ | 18 | 4,080 | 18 | 4,079 |
| Saluria .................................. | 97,663 | 237,294 | 40,165 | 18 | 16,785 | 28 | 24,359 |
| Texas ..................................... | 1,218,034 | 15,876,632 | 349,275 | 163 | 91,913 | 206 | 127,579 |
| Total.................................. | $3,950,239 | $17,193,118 | $1,631,064 | 256 | 148,904 | 302 | 182,903 |

The entrances and clearances in the coastwise trade during the same period, with the number and tonnage of vessels registered, enrolled, and licensed on the above date, are as follows:

| DISTRICTS. | ENTRANCES. | | CLEARANCES. | | REGISTERED, &C. | |
|---|---|---|---|---|---|---|
| | No. | Tons. | No. | Tons. | No. | Tons. |
| Brazos de Santiago.. | 46 | 36,504 | 18 | 11,019 | 14 | 1,546 |
| Corpus Christi...... | 82 | 52,023 | 43 | 9,310 | 35 | 774 |
| Paso del Norte...... | 79 | 14,888 | 71 | 13,567 | .. | .... |
| Saluria............. | 214 | 197,534 | 52 | 11,519 | 46 | 1,612 |
| Texas............... | 453 | 418,645 | 335 | 290,426 | 250 | 18,116 |
| Total.......... | 874 | 719,594 | 519 | 335,841 | 345 | 22,048 |

—On Oct. 1, 1875, there were 10 national banks in the state, of which the resources were as follows: loans and discounts, $1,366,805 99; bonds for circulation, $789,000; bonds for deposits, $175,000; total, including other items, $3,617,757 88. The following were the chief liabilities: capital stock, $1,200,000; surplus and undivided profits, $344,287 28; circulation, $673,102; individual deposits, $1,081,196 02. There are 15 or 20 state banks.—There were 32 m. of railroad in operation in 1854, 451 in 1862, and 711 in 1870. The following table contains the particulars of the different lines for 1875:

| LINES. | TERMINI. FROM | TERMINI. TO | Miles in operation in the state. |
|---|---|---|---|
| Galveston, Harrisburg, and San Antonio | Harrisburg (on the Galveston, Houston, and Henderson) | Luling, Caldwell co. | 155 |
| Galveston, Houston, and Henderson | Galveston | Houston | 50 |
| Gulf, Western Texas, and Pacific | Indianola | Cuero, De Witt co. | 70 |
| Houston and Great Northern* | Houston | Palestine (on the International) | 152 |
| Huntsville branch | Phelps | Huntsville | 8 |
| Columbia division | Houston | Columbia, Brazoria co. | 50 |
| Northern division | Troupe (on the International) | Mineola (on the Texas and Pacific) | 44 |
| Houston and Texas Central | Houston | Red River City | 341 |
| Western division | Hempstead | Austin | 114 |
| Waco branch | Bremond | Waco | 45 |
| International* | Longview (on the Texas and Pacific) | Rockdale, Milam co. | 205 |
| Texas and New Orleans | Houston | West Liberty, Liberty co. | 85 |
| Texas and Pacific | Shreveport, La. | Eagle Ford, Dallas co. (192 m.) | 172 |
| Branch | Marshall | Texarkana (just across the Arkansas border) | 75 |
| Transcontinental division | Sherman (on the Houston and Texas Central) | Brookston, Lamar co. | 56 |
| Total | | | 1,572 |

The Galveston, Harrisburg, and San Antonio railroad is in progress (1876) toward San Antonio, and the extension of the Gulf, Western Texas, and Pacific railroad to that city is contemplated. The Houston and Texas Central railroad connects at Red River City with the Missouri, Kansas, and Texas railroad for St. Louis. The International railroad is intended to extend S. W. to Laredo on the Rio Grande. The Texas and Pacific railroad has permission by its charter to continue its line across the continent to San Diego, Cal.; the Transcontinental division, when completed, will extend from Texarkana to Fort Worth. Tarrant co., on the main line. The Texas and New Orleans railroad was in operation to the Sabine river previous to the civil war, during which it was nearly destroyed; it is to be repaired. The Galveston and Santa Fé railroad has been chartered to connect those two points, and 40 m. are in course of construction from Galveston. The Texas Western railroad (narrow gauge), from Houston to San Antonio, is in progress W. from Houston.—A new constitution was adopted by vote of the people, Feb. 15, 1876, which was to go into effect on the third Tuesday in April following. The executive officers are a governor (annual salary, $4,000), lieutenant governor, secretary of state ($2,000), comptroller of public accounts ($2,500), treasurer ($2,500), commissioner of the general land office ($2,500), and attorney general ($2,000, besides fees not exceeding $2,000). They hold office for two years, and are all elected by the qualified voters, except the secretary of state, who is appointed by the governor and senate. The lieutenant governor is *ex officio* president of the senate, and in that capacity receives the pay of a senator. The legislature consists of a senate of 31 members, elected by districts, and a house of representatives of 93 members, distributed among the counties. At the apportionment in 1880 the number of representatives may be increased to not more than 150. The representatives are elected biennially; the senators hold office four years, one half being elected biennially. The sessions are biennial. Two thirds of each house are necessary to a quorum, and a two-thirds vote is necessary to overcome the governor's veto. Members of the legislature receive not more than $5 for each day's attendance, and not more than $5 for each 25 miles' travel to and from the capital. The judicial authority is vested in a supreme court, a court of appeals, district courts, county courts, and justices of the peace (inferior cases). The supreme court consists of a chief justice and two associates, and has appellate jurisdiction of civil cases of which the district courts have original or appellate jurisdiction. The court of appeals consists of three judges, and has appellate jurisdiction of criminal cases, and of civil cases of which the county courts have original or appellate jurisdiction. The judges of the supreme court and court of appeals are elected by the qualified voters for six years, and receive an annual salary of $3,550 each. A district court is held twice a year in each county, having original jurisdiction of felonies, divorce, land titles, &c., and of civil cases involving $500 and upward, and appellate jurisdiction of probate cases from the county courts. A district judge (annual salary, $2,500; term, four years) is elected by the qualified voters of each of the 26 judicial districts. A county judge is elected by the qualified voters of each county for two years. The county courts have original jurisdiction of misdemeanors, probate cases, and civil cases involving from $200 to $1,000, and appellate jurisdiction of judgments of justices of the peace. The right of suffrage is conferred upon every male citizen of the United States, or person who has declared his intention to become such, of sound mind and not a pauper or convict, who has attained the age of 21 years and has resided one year in the state and six months in the county or district. Elections are by ballot. In elections in cities and corporate towns to determine expenditure of money or assumption of debt only taxpayers may vote. Gen-

* Consolidated as the International and Great Northern.

eral elections are held biennially on the Tuesday next after the first Monday of November in even years (commencing with 1878). Amendments to the constitution must be proposed by two thirds of each house of the legislature, and approved by a majority of the people. Texas is entitled to six representatives and two senators in congress, and therefore has eight votes in the electoral college.—The valuation of property, according to the United States censuses, has been as follows:

| YEARS. | ASSESSED VALUE. | | | True value of real and personal estate. |
|---|---|---|---|---|
| | Real estate. | Personal estate. | Total. | |
| 1850 .. | ............ | ............ | ............ | $52,740,473 |
| 1860 .. | $112,476,013 | $155,316,322 | $267,792,335 | 365,200,614 |
| 1870 .. | 97,186,568 | 52,546,361 | 149,732,929 | 159,052,542 |

The decrease from 1860 to 1870 was due to the civil war, and particularly to the emancipation of the slaves. The assessed value of property in 1874 was $241,841,860; in 1875 it was believed that with a proper system of assessment it would amount to $300,000,000. The taxation of 1873 amounted to $2,517,394, of which $1,286,188 ($168,254 on polls and $1,117,934 on property) was state and $1,231,206 county. The estimated receipts during the year ending Aug. 31, 1876, available for the general expenses of the state, are $1,289,348; available for school purposes, $715,129 70; total, $2,004,477 70, of which $1,400,130 are from taxes on property, $279,000 from occupation tax, $170,347 70 from poll taxes, $125,000 from interest on permanent school fund, and $30,000 from office fees. The appropriations for the same period are as follows: for executive departments, $182,230; judicial department, $256,625; school department, $505,400, including $500,000 for teachers' wages; blind asylum, $16,120; deaf and dumb asylum, $14,000; lunatic asylum, $38,300; penitentiary, $40,000; interest, $480,000; frontier defence, $150,000; other purposes, $5,610; total, $1,688,285. The bonded debt on Aug. 31, 1875, amounted to $4,107,588; floating debt, $614,326 36; total, $4,721,914 36. Besides this there was a debt of doubtful validity, amounting to $829,687 66, and consisting of bonds issued by the state to the school and university funds, with accrued interest thereon.—The state institutions are the penitentiary, at Huntsville, and the institution for the deaf and dumb (opened in 1857), the institute for the blind (1856), and the lunatic asylum (1861), at Austin. The labor of the convicts is leased to contractors. The number registered at the penitentiary in November, 1875, was 1,686, of whom 452 were employed at the penitentiary and the rest elsewhere. The institution for the deaf and dumb in 1874 had 46 pupils (31 males and 15 females); the blind institute, 40 (16 males and 24 females); and the lunatic asylum, 127 inmates (68 males and 59 females). In 1875 an act was passed providing for the erection of two additional penitentiaries, one N. E. of the Trinity river and the other W. of the Colorado river.—The governor, comptroller, and secretary of state constitute a board of education. The public schools are regulated by an act of 1873, with amendments. In each county a board of five school directors is elected for four years; these choose one of their number president, who is *ex officio* county superintendent of public instruction. In each school district three trustees are elected annually. Cities may assume control of the schools within their limits, subject to the general school law. The schools for white and colored children are separate. Under the provisions of the constitution one fourth of the revenue from general taxation and a poll tax of $1 on males between 21 and 60 years of age, together with the interest on the permanent school fund, are annually set apart for the support of public schools; there is also a landed endowment, consisting of 60,314,000 acres of the public domain. In 1874 there were 2,129 public schools, with 98,308 pupils enrolled, out of a school population (6 to 18 years) of 313,061; private schools, 132, with 4,381 pupils; public school houses, 1,007; amount of state school fund apportioned, $499,930 50; teachers' wages, $612,878 67. Only 77 counties reported the number of pupils enrolled in the public schools; the number enrolled in the entire state was estimated by the superintendent of public instruction at 161,670. The permanent school fund on Aug. 31, 1875, amounted to $2,637,673 31. Under acts of congress of 1862 and 1866, the state received a donation of 180,000 acres of land scrip for the establishment of an agricultural and mechanical college. This was sold in 1871, and the proceeds were invested in 7 per cent. gold bonds of the state ($174,000). Buildings have been erected by the state near Bryan. The following table gives particulars of collegiate institutions for 1874–'5:

| INSTITUTIONS. | Location. | Denomination. | Date of organization. | Number of instructors. | Number of students. |
|---|---|---|---|---|---|
| Baylor university.......... | Independence................ | Baptist...................... | 1845 | 7* | 80 |
| Austin college............ | Huntsville.................. | Presbyterian................ | 1850 | 4 | ... |
| University of St. Mary..... | Galveston................... | Roman Catholic............ | 1854 | 10 | 163 |
| Soule university........... | Chappell Hill, Washington co.. | Methodist Episcopal, South. | 1856 | .. | ... |
| Waco university........... | Waco........................ | Baptist...................... | 1857 | 14 | 291 |
| Salado college............. | Salado, Bell co.............. | Non-sectarian............... | 1869 | 5 | 204 |
| Trinity university......... | Tehuacana, Limestone co..... | Cumberland Presbyterian... | 1869 | 18 | 408 |
| Henderson college......... | Henderson, Rusk co.......... | Non-sectarian............... | 1871 | 6 | 200 |
| Texas university........... | Georgetown, Williamson co... | Methodist Episcopal, South.. | 1874 | 6 | 68 |

These institutions, besides the ordinary college course, have preparatory and inferior departments, which embrace the greater part of the students. Several of them admit both sexes. A law department has been organized in Trinity university. The American dental college at Austin, organized in 1873, and the Galveston medical college, founded in 1864, have each six professors. The Barnes institute, at Galveston, Coronal institute at San Marcos, Hays co., St. Mary's Catholic institute, at San Antonio, and the Texas military institute, at Austin, are important. Among female seminaries are the Andrew female college, at Huntsville; Baylor female college, at Independence; Bryan female seminary, Brazos co.; Chappell Hill female college; Lamar female college, at Paris, Lamar co.; Ursuline academy, at Galveston; and Waco female college. The state has set apart 1,221,000 acres of land for the establishment of a university, but no steps have yet been taken to found the institution. There were also in the treasury on Aug. 31, 1874, bonds to the amount of $134,472 26 belonging to the university fund.—The number of libraries returned by the census of 1870 was 455, with an aggregate of 87,111 volumes, of which 135, with 25,018 volumes, were other than private, including 131 Sunday school libraries, with 19,318 volumes. There were 112 newspapers and periodicals, issuing 4,214,800 copies annually and having a circulation of 55,250, viz.: 12 daily, circulation 3,500; 5 tri-weekly, 2,450; 5 semi-weekly, 3,700; 89 weekly, 45,300; and 1 semi-monthly, 300. The following are the statistics of churches, according to the census:

| DENOMINATIONS. | Organizations. | Edifices. | Sittings. | Property. |
|---|---|---|---|---|
| Baptist | 275 | 211 | 61,700 | $196,540 |
| Christian | 18 | 17 | 4,450 | 11,650 |
| Congregational | 1 | 1 | 500 | 5,000 |
| Episcopal | 32 | 31 | 11,400 | 109,400 |
| Jewish | 1 | 1 | 400 | 6,000 |
| Lutheran | 23 | 21 | 7,650 | 47,900 |
| Methodist | 355 | 244 | 69,100 | 251,140 |
| Presbyterian, regular | 86 | 70 | 22,750 | 128,500 |
| " other | 15 | 14 | 4,850 | 14,100 |
| Roman Catholic | 86 | 36 | 16,000 | 264,200 |
| Union | 1 | 1 | 300 | 1,000 |
| Total | 843 | 647 | 199,100 | $1,035,430 |

—In 1685 a colony of French emigrants led by the sieur de La Salle, designing to found a settlement in the delta of the Mississippi, sailed past it unawares, landed in Matagorda bay, and erected Fort St. Louis on the Lavaca. In 1689 Capt. De Leon, a Spanish officer, was despatched to the Lavaca to scour the country and hunt out the French. He arrived there on April 22, found the garrison scattered, and returned the next year with 110 men and some friars, and established on the site of Fort St. Louis the mission of San Francisco. In 1691 a Spanish governor of the region was appointed, and soldiers were sent to enforce his authority; but in 1693 the hostility of the Indians, the failure of the crops, and the death of their cattle discouraged the colonists, and the settlements were abandoned. The Spaniards had settlements at El Paso and at San Juan Bautista, both on the right bank of the Rio Grande, but none within the present bounds of Texas. In 1714 the French again attempted to effect a settlement within its limits, and Crozat, to whom Louis XIV. had granted the whole of Louisiana, sent Huchereau Saint-Denis upon an expedition thither. He penetrated from the Sabine to the Rio Grande, and visited the Spanish mission of San Juan, where he was taken prisoner by the governor of Coahuila; but having subsequently married the daughter of the commandant of that mission, he introduced Spanish missionaries into Texas, who established a mission on the bay of San Bernardo or Matagorda, another west of the Sabine and near the coast (the famous mission of Dolores), and a third on the right bank of the San Pedro, near San Antonio, subsequently removed eastward, and known as the Alamo. Two other missions were established soon after, one near Nacogdoches, the other not far from San Augustine. The name of "the New Philippines" was now given to the country, and in 1715 the marquis de Aguayo was made governor general of the colony. For 20 years the Spaniards held sole sway, and multiplied their settlements. In 1735 Saint-Denis, who had acquired great influence over the Texas Indians, aided in removing a French settlement on Red river into Texas; the Spaniards protested, but owing to quarrels among themselves did not drive them out, and finally conceded that they had a right to the region they were occupying. In 1758 the Indians attacked the mission of San Saba, and killed all its inhabitants. This caused the decline of the missions in Texas, as the slaughter was never avenged; in 1765 there were not more than 750 European inhabitants, with about the same number of domiciled Indians. In 1762–'3 the feud between France and Spain was finally settled by the cession of the vast Louisiana territory by the former power to the latter. In 1803, Spain having re-ceded Louisiana to France, that power sold it to the United States; and as there had been no well defined boundary between Louisiana and the old Spanish possessions W. of it, a controversy at once ensued between Spain and the United States on the question of boundaries, Spain claiming a region E. of the Sabine, and the United States urging that they were entitled to the country W. as far as the Rio Grande. In October, 1806, Gen. Herrera, the Spanish commander, entered into an agreement with Gen. Wilkinson establishing the territory between the Sabine and Arroyo Honda as a neutral ground, and retired W. of that line. At this time the population of Texas was about 7,000, many of the settlers being adventurers engaged in illicit trade between the United States and Mexico. From 1806 a series of revolutionary efforts com-

menced, beginning with the projected movement of Aaron Burr, and embracing the expeditions of Magee, a former lieutenant of the U. S. army; of Col. Kemper, his successor; of Bernardo Gutierrez; of Col. Ellis P. Bean, who had suffered a protracted and cruel imprisonment from the Spanish authorities; of Gen. J. A. Toledo, a Cuban republican; of Col. Perry, an American officer; of Auzy, who styled himself governor of Texas; and of Xavier Mina, a Spanish refugee, who aided in the capture of Galveston island in 1816. In these expeditions there were several severe battles fought between the invaders and the Spanish authorities; on two occasions in 1813, the invaders defeated the Spanish forces, and caused them a loss of more than 1,000. In the same year, of a force of 2,500 Americans and Mexicans, all were slain but about 100, a considerable number being butchered in cold blood, and nearly 700 of the peaceable inhabitants of San Antonio murdered. In 1817 Mina won several victories in conflict with the Spanish troops, but was finally defeated, taken prisoner, and shot on Nov. 11 of that year. After the close of the war of 1812 Lafitte, the pirate of the gulf, made Galveston island his headquarters, and established a town there named Campeachy. He remained here till 1821, when a naval force was despatched by the United States government to break up the settlement. In 1819 the long controversy between the United States and Spain in regard to the Texan boundary was terminated by the establishment of the Sabine as the boundary line. This treaty occasioned much dissatisfaction on the part of the western and southwestern states. Mr. Clay and other prominent men opposed it. A revolutionary expedition was organized at Natchez the same year, under the command of Dr. James Long, a Tennesseean, which penetrated as far as Nacogdoches and established a provisional government there, and the leader went to Galveston island to secure the coöperation of Lafitte; but while he was absent his force was routed and cut to pieces by the royalist troops. In a second expedition Long took possession of La Bahia without difficulty; but, though Mexico had become independent under Iturbide, he and his followers were taken prisoners and sent to the city of Mexico, where after a brief imprisonment he was set at liberty, but was almost immediately assassinated, in 1822. Texas at this time was almost wholly deserted, the settlement at Galveston entirely abandoned, and the few inhabitants at other points reduced to poverty by the civil war. In 1820 Moses Austin, then residing in Missouri, received from the Spanish authorities of Mexico a grant of lands in Texas. He died before he was able to avail himself of it, and his son, Stephen F. Austin, received a confirmation of the grant in 1823, having already in the beginning of 1822 conducted a considerable number of colonists to the site he had selected in the vicinity of the present county of Austin. The colony increased rapidly, and Austin obtained permission to bring in 500 more families (his first grant was for 300). Others also followed in the establishment of colonies in the same vicinity. The Mexican constitution, adopted in 1824, united Coahuila, hitherto a separate province, with Texas in a single state, and the congress of the united state placed a Mexican as commandant of the department of Texas. The injustice of this commandant toward the American citizens, especially those attached to the colony of Hayden Edwards, created difficulty; and an appeal being made to the governor of the state, who was also a Mexican, he without trial or examination annulled Edwards's grant and ordered his expulsion from the state. Edwards and his colonists attempted unsuccessfully to effect a revolution; and in January, 1827, they were compelled to retreat into the United States. In 1830 Bustamante, who had seized the dictatorship of Mexico, issued a decree forbidding the people of the United States to enter Texas as colonists, and suspending all colony contracts which interfered with this prohibition. In 1832 the Texans sustained the *pronunciamiento* of Vera Cruz in favor of the constitution, and in opposition to the rule of Bustamante, and defeated a force under Col. Piedras, who favored the dictator. In 1833 the American settlers, now numbering over 20,000, held a convention, determined to separate themselves from Coahuila, and prepared a state constitution and an address to the general government, of which Santa Anna was now the head, requesting admission as a separate state into the republic. Col. S. F. Austin went to Mexico to present the request of the memorialists. He was unsuccessful, and was detained in Mexico till September, 1835, but in 1834 procured the revocation of the decree of Bustamante prohibiting the admission of colonists from the United States, and several other favorable concessions. Santa Anna sought to amuse Austin and the Texans with promises of allowing them a separate state government till he could occupy the country with his troops. The government of the state of Coahuila and Texas having been overthrown, committees of safety were established, the first being appointed at a meeting at Mina (now Bastrop), May 17, 1835. The first battle, or rather skirmish, was fought near Gonzales, Oct. 2. Other battles followed. Goliad was captured by the Texans on Oct. 9, and the battle of Concepcion, near San Antonio, was fought on the 28th. On Nov. 3 the "Consultation," a body composed of delegates from the municipalities, met at San Felipe de Austin, and proceeded to the organization of a provisional government. Henry Smith was elected governor and J. W. Robinson lieutenant governor, and a general council was organized. At the same time Sam Houston was elected commander-in-chief, and Austin

was appointed a commissioner to the United States. San Antonio de Bexar was taken on Dec. 10, after being cannonaded for six days. By this victory the entire armed Mexican force was driven out of Texas. On the 20th a "Declaration of Independence" was issued at Goliad by Capt. Philip Dimitt and others there. Santa Anna set out with an army of 7,500 men, well provided with artillery, ammunition, and stores. On Feb. 23, 1836, he invested the Alamo, a strong fort near San Antonio, which was garrisoned at this time by 140 men under command of W. B. Travis, and 32 more subsequently forced their way through the Mexicans into it. Santa Anna with 4,000 men bombarded it for 11 days, and finally carried it by storm. On March 6 the whole garrison were put to the sword, and but three persons, a woman, a child, and a servant, were spared. The Mexican loss was 1,600. On March 1 a convention assembled at Washington on the Brazos, and on the 2d issued a declaration of independence; on the 16th a provisional president (David G. Burnet) and other officers were elected, and a constitution was adopted, which was signed on the 17th. Meanwhile Gen. Houston found it necessary on the approach of Santa Anna to evacuate Gonzales. The tragedy of the Alamo, the murder of Col. Fannin's command in cold blood at Goliad, March 27, 1836, by Santa Anna's order, in violation of the terms of surrender (see FANNIN, JAMES W.), and the successive defeats of the Texan troops, produced a temporary panic. This was increased by the continued retreat of Gen. Houston, who fell back first to the Colorado, then to the Brazos, and finally to the San Jacinto, his design being to scatter and divide the Mexican force, in which he was eminently successful. The alarm soon passed away, and having collected a force of about 800 troops, he gave battle on April 21 to the Mexican forces which had pursued them, of about twice the number, and defeated them completely, killing 630, wounding 208, and taking 730 prisoners; among the latter (though not captured till the next day) was the Mexican president, who had commanded in person. The Mexicans were at once demoralized, and retreated rapidly westward in disorder. Santa Anna was held a prisoner, but the war was practically ended; and though the Mexican government made several attempts to fit out other armies to reconquer Texas, and refused to acknowledge its independence, their forces did not again invade the country. Gen. Houston, who had been wounded in the battle of San Jacinto, and had resigned his command of the army, was elected president in September, 1836, and on Oct. 22 was inaugurated. The first congress of the republic assembled about the same time, the constitution having been adopted in the election of September. In March, 1837, the United States acknowledged the independence of Texas. In 1838 Mirabeau B. Lamar succeeded Gen. Houston as president. Repeated incursions were made by the Comanches and other Indian tribes; and in 1840 the Texans pursued them after one of their forays, penetrated into their country, and inflicted summary and severe punishment. In 1839 the independence of the republic was acknowledged by France, and in 1840 by England, Holland, and Belgium. But while thus recognized by leading powers as independent, her financial condition was every month becoming more deplorable. In September, 1841, Gen. Houston was again elected president. In 1841 and 1842 the Mexican government sent several marauding expeditions into Texas, and in the latter year San Antonio was twice captured and plundered. The Texans attempted reprisals by two ill-judged expeditions, neither under the direction of the government, the first in 1841 to Santa Fé, the second in 1842 to Mier in the state of Tamaulipas. Both were unsuccessful, and many of the Texans were taken prisoners by the Mexicans and executed. In the spring of 1843 a third expedition, intended to intercept the Mexican traders to Santa Fé, was fitted out by private parties, but with the approbation of the government, which also proved a failure. The same year, on the remonstrance of the British chargé d'affaires to Mexico, Santa Anna informed Gen. Houston that he would agree to an armistice, and commissioners were appointed. While the negotiations were pending, President Tyler made propositions to the president of Texas for her annexation to the United States, which after a time were favorably received, and a treaty was made looking to annexation. This treaty was completed and signed by the Texan commissioners and Mr. Calhoun, secretary of state, April 12, 1844; but was rejected by the United States senate on June 8. The agitation of this subject greatly irritated Mexico, and caused her to terminate the armistice and threaten the renewal of hostilities; it also displeased Great Britain and France, who desired to see Texas under an English or joint protectorate, without slavery, and free from the influence of the United States. In December, 1844, Dr. Anson Jones was inaugurated president of the republic. Its revenues were now increasing, and its population growing with great rapidity, and the threats of war from Mexico were rendered powerless by her weakness and dissensions. The only disturbances within the boundaries of Texas were the conflicts between the "regulators" and the "moderators" in Shelby and adjacent counties. These were finally put down by armed force. Joint resolutions providing for the annexation of Texas passed the United States house of representatives by a vote of 120 to 98, Jan 25, 1845, and the senate by a vote of 27 to 25 on Feb. 27, with an amendment, which was concurred in by the house the next day by a vote of 132 to 76. On March 1 these resolutions were approved by President Tyler.

President Jones called a convention of 61 delegates to meet on July 4 to consider the propositions for annexation, and that convention ratified the act and prepared a constitution for the republic as a state of the federal Union, which was submitted to the people and approved by them. On Dec. 29 a joint resolution of congress declared Texas admitted into the Union as a state. Its annexation led to a war with Mexico, which terminated in 1848. (See Mexico.) Under the Spaniards Texas was bounded W. by the Nueces and N. by Red river, but at the time of its annexation the republic claimed as its W. boundary the Rio Grande and a line running N. from the source of that stream to the 42d parallel, making its area 376,133 sq. m. In 1850 the state ceded to the United States its claim to all territory beyond its present limits, in consideration of $10,000,000 in bonds, with the proceeds of which the state debt was paid. At the presidential election in 1860, 47,548 votes were cast for the Breckinridge electors, and 15,438 for the Bell electors. As soon as the election of Lincoln became known, the secessionists began to urge the governor (Sam Houston) to call an extra session of the legislature, which he for some time refused to do. Finally, the secessionists having called an irregular convention, the governor assembled the legislature on Jan. 21, 1861, which sanctioned the convention thus called. The convention met on Jan. 28, and on Feb. 1 adopted an ordinance of secession by a vote of 166 to 7, which on Feb. 23 was ratified by the people by a vote of 34,794 to 11,235. The governor having neglected to take the oath of allegiance to the confederacy, as required by the convention, an ordinance was passed on March 16 declaring his seat vacant, which action was confirmed by the legislature on the 20th. The permanent constitution of the Confederate States was ratified on March 23 by a vote of 68 to 2. In the mean time, on Feb. 18, Gen. Twiggs, in command of the United States forces in Texas, surrendered his entire command and all the military posts and munitions of war to the state authorities. No very important military operations occurred in the state during the war. Galveston was occupied by a federal force on Oct. 8, 1862, but it was retaken by the confederates on Jan. 1, 1863. On Oct. 26 Gen. Banks set out from New Orleans with an expedition under the immediate command of Gen. Dana, and landed at Brazos Santiago on Nov. 2. Brownsville was entered on the 16th, and other points in western Texas were occupied. The last fight of the war took place in western Texas on May 13, 1865, between a federal force under Col. Barret and a confederate force under Gen. Slaughter, the latter being victorious. On the 26th Gen. Kirby Smith surrendered the last confederate army. On July 21 Gen. A. J. Hamilton, appointed provisional governor by President Johnson, arrived at Galveston. An election was held on Jan. 8, 1866, for delegates to a state convention, those being entitled to vote who were qualified according to the laws in force prior to secession, and who had taken the amnesty oath prescribed by the president's proclamation of May 29, 1865. The convention met on Feb. 10 and adjourned on April 25, having adopted amendments to the constitution declaring the ordinance of secession void, abolishing slavery, and repudiating the war debt. At an election held in June these amendments were ratified, and J. W. Throckmorton was chosen governor. On Aug. 13 he entered upon his duties. Under the reconstruction acts of 1867 Texas with Louisiana was constituted the fifth military district under Maj. Gen. Sheridan, and was placed in immediate command of Brev. Maj. Gen. Charles Griffin. Gen. Sheridan assumed command March 19, 1867. On July 30 Gov. Throckmorton was removed, and E. M. Pease appointed in his place. Several changes of military commanders subsequently took place. On a registration, 59,633 white and 49,497 colored voters were enrolled. At an election in February, 1868, a convention was called, which assembled on June 1 and remained in session till Aug. 31, when it took a recess. Reassembling on Dec. 7, it adopted a constitution, and adjourned in February, 1869. At an election held Nov. 30 to Dec. 3, 1869, the constitution was ratified by a vote of 72,366 to 4,928, and E. J. Davis, republican, was chosen governor over A. J. Hamilton, conservative republican. The legislature elected at the same time assembled on Feb. 8, 1870, and ratified the 14th and 15th amendments to the constitution of the United States. On March 30 an act was passed readmitting the state to representation in congress, and on April 16 the government was turned over to the civil authorities. Within the last few years Texas has suffered severely from Indian incursions on the N. W. frontier and Mexican raids on the Rio Grande.

**TEXAS**, a S. county of Missouri, drained by Current river and affluents of the Gasconade; area, 1,250 sq. m.; pop. in 1870, 9,618, of whom 95 were colored. The surface is hilly, with large forests of yellow pine, and the soil fertile along the streams. The chief productions in 1870 were 51,778 bushels of wheat, 256,252 of Indian corn, 29,876 of oats, 16,318 of potatoes, 44,349 lbs. of tobacco, 13,238 of wool, 67,231 of butter, and 601 tons of hay. There were 2,061 horses, 2,399 milch cows, 4,424 other cattle, 7,393 sheep, 15,284 swine, and 6 saw mills. Capital, Houston.

**TEXEL**, an island of the Netherlands, in the North sea, province of North Holland, separated from the mainland by the channel called Mars Diep, about 2 m. broad; extreme length 14 m., breadth 6 m.; area, 74 sq. m.; pop. in 1869, 6,145. It contains several villages, the most important of which is Burg. The surface is low and a great deal of it marshy, but it is protected from inundations by the line of

dunes or sand hills on the W. side, and strong dikes in other parts. The soil is remarkably fertile, and is chiefly occupied by pastures.

**TEXIER, Charles Félix Marie**, a French archæologist, born in Versailles, Aug. 29, 1802. He studied architecture at the school of fine arts in Paris, was employed for ten years in explorations in the East under the patronage of the government, and was afterward inspector of public buildings in France and Algeria. His works, remarkable for learning and magnificent illustrations, include *Description de l'Arménie, de la Perse et de la Mésopotamie* (2 vols. fol., Paris, 1842–'5); *Description de l'Asie Mineure* (4 vols., 1839 *et seq.*, and simultaneously in English by R. P. Pullan); *Édesse et ses monuments en Mésopotamie* (1859); and in conjunction with Pullan, "Byzantine Architecture" (London, 1864), and "The Principal Ruins of Asia Minor" (1865).

**TEZCUCO, or Tezcoco**, a town of Mexico, in the state and about 16 m. E. N. E. of the city of Mexico, near the E. shore of the lake of the same name; pop. about 5,000. It contains several handsome buildings, public and private. Woollen and cotton goods are manufactured. In ancient times Tezcuco was the second city in Mexico. One of the palaces of Montezuma is said to have stood in the N. W. quarter, and in the S. part there are massive remains of three pyramids, each measuring 400 ft. along the base of their fronts.

**THACHER, James**, an American physician, born in Barnstable, Mass., Feb. 14, 1754, died in Plymouth, May 26, 1844. On the breaking out of the revolution he was appointed surgeon's mate to Dr. John Warren in the general hospital at Cambridge; in 1778 he was made chief surgeon to the first Virginia state regiment, and in 1779 was transferred to a New England regiment. In March, 1783, he settled as a physician at Plymouth, Mass., where he also gave some attention to the manufacture of salt and iron. He published "The American New Dispensatory" (Boston, 1810), which was long a standard work on pharmacy, medical chemistry, and materia medica; "Observations on Hydrophobia" (1812); "The Modern Practice of Physic" (1817; 2d ed., 1826); "The American Orchardist" (1822; 2d ed., 1825); "A Military Journal during the Revolutionary War" (1823; 3d ed., Hartford, 1854); "American Medical Biography" (2 vols. 8vo, 1828); "A Practical Treatise on the Management of Bees" (1829); "An Essay on Demonology, Ghosts, Apparitions, and Popular Superstitions" (1831); and "History of the Town of Plymouth" (1832; 2d ed., 1835).

**THACHER, Peter**, an American clergyman, born in Milton, Mass., March 21, 1752, died in Savannah, Ga., Dec. 16, 1802. He graduated at Harvard college in 1769, and settled at Malden, Mass., in 1770. He soon attained a high reputation as a preacher, and received the name of the "silver-tongued Thacher." From January, 1785, till his death, he was pastor of the Brattle street church in Boston. His "Oration against Standing Armies," delivered at Watertown in 1776, still retains its reputation. For 15 years he was chaplain of one or both branches of the legislature. He published 22 distinct works, including "Observations on the State of the Clergy in New England" 1783), and "Memoirs of Dr. Boylston" (1789).

**THACKERAY, William Makepeace**, an English author, born in Calcutta in 1811, died in London, Dec. 24, 1863. He was descended from an old Yorkshire family. His father was in the civil service of the East India company. He was educated at the Charterhouse in London, and at Cambridge, but did not take a degree. Coming into possession of £20,000 at the age of 21, he travelled on the continent, and studied art for several years. But he lost the bulk of his fortune by speculation, and about the age of 30 adopted literature as a profession. He wrote for "Fraser's Magazine" under the pseudonymes of Michael Angelo Titmarsh and George Fitz-Boodle, and contributed to "Punch" three series of papers: "The Fat Contributor," "Jeames's Diary," and "The Snob Papers." These and other works appeared in book form from 1840 to 1848, but he attained no very marked success in literature till the publication of "Vanity Fair, a Novel without a Hero," in monthly numbers, in 1846–'8. This gave him a reputation as a novelist which, though amply sustained, was hardly increased by any of his later works. In 1845 he visited the East for his health. He was called to the bar in 1848, but did not practise. In 1851 he delivered to brilliant audiences in London a series of lectures on "English Humorists of the Eighteenth Century." He visited America in 1852, and again in 1855–'6, where he repeated this course, and also delivered for the first time another course on "The Four Georges," which he repeated in the principal cities of Great Britain. In 1857 he was an unsuccessful candidate, as a liberal, for the representation of the city of Oxford in parliament. The "Cornhill Magazine" was commenced at the close of 1859 with Thackeray as editor, and quickly attained an enormous circulation. He resigned the editorship in April, 1862. He was found dead in his bed, from effusion on the brain. He was buried in Kensal Green cemetery. A bust of him, by Marochetti, was unveiled in Westminster abbey, Oct. 21, 1865. He was tall and powerfully built, with a massive head and silvery white hair. His geniality, even temper, and kindly disposition toward everybody with whom he came into personal relations, were curiously at variance with the charge of cynicism so often brought against his works. His domestic life was clouded for several years by the insanity of his wife. His novels and tales, with the dates of their publication in book form, are: "The Great Hoggarty Diamond" (1841); "The Memoirs of Barry Lyndon" (1843); "Vanity Fair" (1848);

"The History of Pendennis" (1850); "The History of Henry Esmond" (1852); "The Newcomes" (1855); "The Virginians" (1859); "Lovel the Widower" (1860); "The Adventures of Philip on his Way through the World" (1862); and "Denis Duval," left unfinished (1864). His Christmas books are: "Mrs. Perkins's Ball" (1846); "Our Street" (1848); "Dr. Birch and his Young Friends" (1849); "Rebecca and Rowena" (1850); "The Kickleburys on the Rhine" (1851); and "The Rose and the Ring" (1854). His other publications include "The Paris Sketch Book" (1840); "Comic Tales and Sketches" (2 vols., 1841); "The Second Funeral of Napoleon" and "The Chronicle of the Drum," in verse (published together, 1841); "The Irish Sketch Book" (2 vols., 1843); "Notes of a Journey from Cornhill to Grand Cairo" (1846); "The Book of Snobs" (1848); "English Humorists of the Eighteenth Century" (1853); "Ballads" (1855); "The Four Georges" (1860); "Roundabout Papers" (1862); and "The Orphan of Pimlico, and other Sketches, Fragments, and Drawings," with notes by his daughter (1875). Most of his books were illustrated by himself. James T. Fields has made a collection of his fugitive articles, under the title "Early and Late Papers" (12mo, Boston, 1867). There are numerous approximately complete editions of Thackeray's works, the latest of which reproduces the original illustrations (22 vols., London, 1875 *et seq.*).—See "Studies on Thackeray," by James Hannay, and "Thackeray, the Humorist and the Man of Letters: the Story of his Life," by Theodore Taylor (London, 1864).—His daughter ANNE ISABELLA has published "The Story of Elizabeth" (London, 1863; German translation, Leipsic, 1864; Dutch, Amsterdam, 1864); "The Village on the Cliff" (1867); "Old Kensington" (1873); "Toilers and Spinsters, and other Essays" (1873); "Bluebeard's Keys" (1874); "Miss Angel," a novel founded on the life of Angelica Kauffmann (1876); and numerous short tales and sketches.

**THAER, Albrecht**, a German agricultural writer, born in Celle, May 14, 1752, died at Mögelin, near Potsdam, Oct. 26, 1828. He studied at Göttingen, and in 1780 was appointed court physician at Hanover. In 1790 he established an agricultural school at Celle, in 1804 entered the Prussian civil service, and in 1807 erected on his estate of Mögelin an institution since known as the royal school of agriculture. In 1810 he was appointed professor of agriculture and political economy in the university of Berlin, with a seat in the ministry of the interior. In 1815 he became superintendent of the royal establishments for breeding sheep. His great work, *Grundsätze der rationellen Landwirthschaft* (4 vols., Berlin, 1809; 6th ed., 1868), has been translated into English by W. Shaw and C. W. Johnson ("The Principles of Agriculture," 2 vols., London, 1844; 1 vol., New York, 1849), and into other languages. Among his other works are: *Einleitung zur Kenntniss der englischen Landwirthschaft* (3 vols., Hanover, 1798–1804; 3d ed., 1816); *Ueber die feinwollige Schafzucht* (Berlin, 1811); and *Leitfaden zur allgemeinen landwirthschaftlichen Gewerbslehre* (1816). A monument was erected to him at Leipsic, Sept. 28, 1850, and one designed by Rauch at Berlin, Nov. 15, 1860.—See *Albrecht Thaer*, by Wilhelm Körte (Leipsic, 1839).

**THAIS**, an Athenian courtesan, who accompanied Alexander the Great on his expedition to Asia. She is said to have instigated him to set fire to the citadel of Persepolis, the residence of the Persian kings, in revenge for the injuries done to her native city by Xerxes; but this is probably untrue, as we know on the authority of Arrian that it was his intention to sack the place and burn the citadel on grounds of state policy. After the death of Alexander, Thais became the mistress of Ptolemy Soter, and, according to Athenæus, was afterward married to him. She was celebrated for wit and repartee.

**THALBERG, Sigismond**, a Swiss pianist, born in Geneva, Jan. 7, 1812, died in Naples, April 27, 1871. He was the natural son of Prince Dietrichstein, and was placed under the instruction of Hummel, whom he subsequently surpassed in firmness of touch and grace of expression. At 15 he began to be known in the concert rooms, and soon afterward published his first compositions. From 1830 to 1839 he made extended concert tours through Europe, appearing in England in 1837. He visited South America and the United States in 1856–'8. His playing was distinguished by precision, delicacy, and finish, rather than by the production of surprising effects; but his chief merit, both as a performer and a composer, consisted in his successful attempts to combine the elements of song and harmony and of brilliant execution, as exemplified respectively in the schools of Mozart and Beethoven and of Clementi. In pursuance of this design he discovered many ingenious combinations for the fingers, whereby the song or melody, which he kept in the medium keys of the piano, could always be heard strongly accented in the midst of rapid passages, scales, arpeggios running from end to end of the instrument, and other complicated forms of accompaniment. This species of composition has since become exceedingly common, through the works of a host of imitators. Among the productions by which Thalberg and his method acquired their celebrity are a series of fantasias of great beauty and brilliancy, including those on themes from *Don Giovanni*, *Robert le Diable*, *L'Elisire d'amore*, *Les Huguenots*, *La donna del lago*, and *Mose en Egitto*, the performance of any one of which by the composer realized the perfection of pianoforte playing. In 1851 he produced at London under Balfe's direction an opera entitled *Florinda*, founded on a libretto by Scribe, which failed to attract much attention.

In 1845 he married a daughter of Lablache. His last public appearance was at Paris in 1865. After that he retired to his estate near Naples, where he devoted himself to the cultivation of the vine.—His daughter ZAIRE, born in New York in 1858, made a successful début as Zerlina in *Don Giovanni*, at Covent Garden, London, April 10, 1875.

**THALER** (Dan. and Swed. *daler*), a coin and money of account of Germany, Austria, Holland, Belgium, Denmark, Sweden, and Norway. Silver coins of an ounce weight were struck in the early part of the 16th century at Joachimsthal, a town in Bohemia, whence the name. (See DOLLAR.) Other countries after a time began to coin thalers, but not always of the same value, and hence originated the *Laubthaler* or leaf dollar, the *Philippsthaler*, the Swedish copper dollar, &c. In most of the countries of Europe the royal or imperial mints coined thalers, hence called *rigsdaler*, *riksdaler*, or *Reichsthaler*, that is, dollar of the realm. These varied in value according to the amount of alloy. (See COINS.) As money of account there is still greater diversity of values, owing to the depreciation of the issues of the national banks or treasuries. In Sweden the *rigsdaler riksmynt*, now the authorized money of account, is about 27 cts. In Denmark the *rigsbank daler* is about 54 cts. In Germany generally the *thaler* of account is reckoned at 69 to 73 cts. American currency.

**THALES**, a Greek philosopher, and one of the seven wise men, born in Miletus, Ionia, about 636 B. C., died probably about 546. He took an active part in the political affairs of his native country. He visited Crete and Egypt, and acquired in the latter country an acquaintance with geometry. Various physical discoveries are attributed to him. He measured the height of the Egyptian pyramids by observation of the time at which a shadow equalled in length the height of the object; and he is said to have computed the sun's orbit, to have fixed the length of the year at 365 days, and to have been the first among the Greeks to predict eclipses, though very vaguely. Aristotle calls him the originator of the Ionic natural philosophy, and hence, indirectly, of Greek philosophy in general. He taught that all things are instinct with life, and originate from water. The writings attributed to him were declared spurious in antiquity, and his sayings recorded by Aristotle and Diogenes Laërtius are probably conjectural.

**THALIA**, in Greek mythology, the muse of comedy and idyllic poetry. She is generally represented with a mask in one hand and a shepherd's staff or a wreath of ivy in the other.

**THALLIUM** (Gr. θαλλός, a green bough), one of the three metals forming the class of triads, the others being iridium and gold. It was discovered by Crookes of London in 1861, in the seleniferous residue from the manufacture of sulphuric acid from iron pyrites. Its discovery resulted from the observation by Mr. Crookes of a green band in the spectrum of the vaporized portion of the residue. It is widely diffused as a constituent of iron and copper pyrites, but forms only about the 4,000th part of the mass. It also exists in the lepidolite of Moravia, in mica from Zinnwald in Bohemia, in the mother liquors of the salt works at Nauheim, and in the mineral crookesite from Skrikerum in Norway. It is most economically prepared from the flue dust of pyrites burners. This dust is stirred with boiling water in wooden tubs, and the decanted or syphoned liquor treated with an excess of strong hydrochloric acid, by which impure monochloride of thallium is precipitated. This impure chloride is then treated with hot oil of vitriol, and contaminations of other metals are separated by sulphuretted hydrogen. A pure sulphate is obtained, from which the metal may be separated by electrolysis or the action of zinc. Thallium resembles cadmium in color, but approaches lead in specific gravity, having a density of 11·8 to 11·91, according to its metallurgic treatment. The symbol of thallium is Tl; its atomic weight, according to recent extended researches by its discoverer, is 203·642. (See "Chemical News," London, 1874.) It has a highly crystalline structure, and crackles like tin when bent, but is easily hammered into leaves. It melts at 561° F. A polished piece of the metal tarnishes rapidly when exposed to the air, but the action continues only a short time, as the thin film of oxide protects it from further oxidation. The metal and its compounds impart an intense green color to colorless flames, which when viewed by the spectroscope is found to be monochromatic, appearing as a sharply defined green band. It forms numerous compounds, including three oxides, the most important being thallous oxide, $Tl_2O$; this dissolves readily in water, producing a caustic alkaline solution which absorbs carbonic acid from the air. The sulphate forms with aluminic sulphate an octahedral alum. The salts of thallium are poisonous. The metal has been used to render glass highly refractive.

**THAMES**, a river of Connecticut, formed by the junction of the Quinebaug (with its branch the Shetucket) and Yantic rivers at the city of Norwich, and flowing thence S. about 15 m. to Long Island sound, which it enters below New London. It is wide and beautiful, navigable for large vessels to Norwich, and has an excellent harbor at its mouth. The streams which form it possess numerous valuable mill sites, and the large amount of manufactured goods from the factories on their banks make the Thames an important avenue of commerce.

**THAMES**, a river of Ontario, Canada, flowing through a fertile country in the peninsula formed by Lakes Huron and Erie, and after a S. W. course of about 160 m. discharging into Lake St. Clair. It is navigable for small vessels from its mouth to Chatham, 18 m. The city of London is the most important place on its banks.—At the Moravian settlement on this

river, Oct. 5, 1813, the battle of the Thames was fought between the British under Gen. Proctor, with an auxiliary force of 2,000 Indians led by Tecumseh, and the Americans under Gen. W. H. Harrison. The American cavalry, commanded by Col. Richard M. Johnson, opened the battle, and defeated the enemy. Tecumseh was killed, and 600 prisoners, six pieces of cannon, and large quantities of stores were taken by the Americans.

**THAMES,** or **Isis** (anc. *Tamesis* or *Tamesa*), the largest and most important river of England. Its source, called Thames Head, is in the Cotswold hills, about 3 m. S. W. of Cirencester, 376 ft. above the sea level. In the first 30 m. of its course it receives the Churnet, the Coln, and the Lech, and below Lechlade becomes navigable for barges; from Lechlade its course is first E. and then N. N. E. and S. S. E. to Oxford, through a level country, the river receiving on its way the Windrush and the Cherwell. Flowing generally S. S. E. from Oxford to Reading, it receives the Thame and the Kennet; thence making a considerable circuit to the north by Henley, Great Marlow, and Maidenhead, it turns eastward to Windsor, then makes a detour southeastward by Staines and Chertsey to Kingston, where it turns N., and, passing Richmond, reaches Brentford, whence its course is nearly due E. to its mouth. From Brentford it passes by Putney, Hammersmith, and Chelsea to London, receiving in its course the Loddon, Colne, Mole, Cran, Brent, and Wandle, all small streams. From London to its mouth, nearly 60 m., the Thames is navigable for vessels of 700 or 800 tons, and for vessels of any burden to Deptford, 3 m. S. E. of London bridge. It is about 300 yards wide at London bridge; at Woolwich, 9 m. below, 500 yards; at Coalhouse point, 20 m. further down, 1,300 yards; at the Nore, 6 m.; and at its mouth, 18 m. Below London it receives the Ravensbourne, Roding, Darent, and Medway. Its tide is perceptible as far as Teddington, 72 m. above its mouth. The Thames and Severn canal connects it with the Severn; the Oxford canal with the grand canal system of the central counties; the Wilts and Berks and the Kennet and Avon canals with the Avon and the Severn; the Wey and Arun and the Basingstoke canals with the Sussex coast; the Grand Junction, the Regent's, and the Paddington canals connect the Brent with the Oxford canal, and encircle the N. and E. sides of the metropolis. The whole course of the Thames is about 220 m. Its commerce is surpassed probably by that of no river in the world. Its docks are described in the article Dock. It is crossed at and above London by numerous bridges, and several tunnels pass under it. For a description of the bridges, the tunnels, and the new Thames embankments, see London, vol. x., pp. 592 and 617.

**THAN, Móricz,** a Hungarian painter, born at Old Becse in 1828. After studying law at Pesth, he devoted himself to painting at the academy of Vienna, and spent some time in Paris, where in 1855 he painted the battle of Mohács. He resided for a time at Rome, receiving instruction from Cornelius and Overbeck, and then settled in Pesth. His works include "Angelica and Medor," "The Tragedy of Mankind," fine altarpieces and frescoes, and the "Love of Fata Morgana," which figured at the Paris exhibition of 1867.

**THANET, Isle of,** an island of England, on the N. coast of Kent, separated from the mainland by branches of the river Stour called the Stourwantsome, the Mele-stream, and the Nethergong-wantsome; length 10 m., breadth 5 m.; area, about 40 sq. m.; pop. in 1871, 30,134. The most important towns are the watering places Ramsgate, Margate, and Broadstairs. The N. E. point of the island is called the North Foreland, and has a lighthouse. The surface, elevated and nearly level, is cultivated with great care. In the time of the Romans the channel on the N. W. side, now almost closed, was from 1½ to 4 m. wide, and was used as the main passage for vessels going toward London; and it continued to be navigable for vessels of considerable size till the time of the Norman conquest. The island was then nearly circular, but it is now an irregular oval. The washing away is still going on, and the average annual loss is estimated at 2 ft. on the N. side, and 3 ft. on the S. side between Ramsgate and Pegwell bay.

**THANKSGIVING DAY,** an annual religious festival, observed in the United States, and particularly in New England, suggested by the Hebrew feast of tabernacles, or "feast of ingathering at the end of the year." The occasional observance of a day of thanksgiving, formally recommended by the civil authorities, was not unusual in Europe, and such a day was observed in Leyden, Holland, Oct. 3, 1575, the first anniversary of the deliverance of that city from siege. In 1608 the Pilgrim church, exiled from England, went to Holland, and remained there till 1620, when it sent off the Mayflower colony to New England. After the first harvest of the colonists at Plymouth in 1621, Gov. Bradford sent four men out fowling, that they "might after a more special manner rejoice together." In July, 1623, a day of fasting and prayer was appointed on account of drought. Rain came abundantly while they were praying, and the governor appointed a day of thanksgiving, which was observed with religious services. The Charlestown records show a similar change of fast day into thanksgiving in 1631 on account of the arrival of supplies from Ireland. In June, 1632, Gov. Winthrop, of the Massachusetts Bay colony, recommended a day of thanksgiving on account of action of the British privy council favorable to the colonies, and invited the governor of Plymouth colony to unite with him. There is record of the official appointment of days of thanksgiving in Massachusetts Bay in 1633, 1634, 1637, 1638, and

1639, sometimes of more than one day in the same year, and in Plymouth in 1651, 1668, 1680 (when the form of the recommendation indicates that it had become an annual custom), 1689, and 1690. The earlier of these appointments were at different seasons of the year, and for special reasons, particularly for the arrival of ships with provisions and new colonists; but the later were more generally for the harvest, and were in the late autumn or early winter. Occasional thanksgiving days were appointed by the Dutch governors of New Netherland in 1644, 1645, 1655, and 1664, and by the English governors of New York in 1755 and 1760. During the revolution thanksgiving day was a national institution, being annually recommended by congress; but after the general thanksgiving for peace in 1784 there was no national appointment till 1789, when President Washington, by request of congress, recommended a day of thanksgiving for the adoption of the constitution. Washington issued a second thanksgiving proclamation in 1795 on account of the suppression of insurrection. President Madison, by request of congress, recommended thanksgiving for peace in April, 1815. But the official recommendation of thanksgiving day was mainly confined to New England, where regular annual proclamations were issued by the governors of the states, and the day was observed almost universally with religious services, and was the principal social and home festival of the year. The prayer book of the Protestant Episcopal church, ratified in 1789, recommends for a day of thanksgiving the first Thursday in November, unless another day be appointed by the civil authorities. There was occasional recommendation by other religious bodies, and various local customs prevailed in different parts of the country; but the day was not regularly recommended by the governor of New York till 1817, and its adoption in the southern states was much later. In 1855 Gov. Johnson of Virginia recommended a day of thanksgiving; but in 1857 Gov. Wise, being requested to do so, publicly declined, because unauthorized to interfere in religious matters. In 1858 thanksgiving proclamations were issued by the governors of eight of the southern states. During the civil war President Lincoln issued proclamations recommending special thanksgiving for victory in 1862 and 1863, and a national proclamation of the annual thanksgiving day in 1863 and 1864. Since that time such a proclamation has been issued annually by the president, as well as by the governors of the states and the mayors of the principal cities; and custom has fixed the time for the last Thursday in November.

**THASOS** (now *Thasso*), the most northerly island of the Grecian archipelago, belonging to Turkey, lying off the S. coast of Roumelia (vilayet of Salonica), nearly circular in form; area, about 85 sq. m.; pop. about 6,000, mostly Greeks. The centre of the island is occupied by Mt. Ipsario, a summit about 3,500 ft. above the sea, and thickly covered with fir trees. The principal ancient town, bearing the same name, was upon three eminences near the N. coast, and some remains of it still exist. The soil is not fertile, and the inhabitants, scattered in about a dozen small villages, do not produce grain enough for their own consumption. The vine was formerly cultivated, and the wine of Thasos was celebrated, but little or none is now produced. In ancient times it contained also valuable gold mines, opened by the Phœnicians, and marble quarries.—Thasos was once of great importance. It was said to have been settled by the Phœnicians, led by Thasos, the son of Agenor, when in search of Europa. Toward the close of the 8th century B. C. it was colonized by settlers from Paros, who very soon became powerful, and obtained considerable possessions also on the coast of Thrace. The gold mines worked by the islanders were very productive, leaving them a clear surplus revenue of about $300,000 annually. They were subdued by the Persians, and afterward became dependent on the maritime empire of Athens; but in 465, in consequence of disputes, the Athenians subjugated and despoiled the island, after a siege of more than two years. Its subsequent history is one of almost constant conflict with Athens, to which it was nominally subject, until the time of the Roman wars, when it submitted to Philip V. of Macedon; but after the battle of Cynoscephalæ (197) it became a free state.

**THATCHER, Benjamin Bussey**, an American author, born in Warren, Me., Oct. 8, 1809, died in Boston, July 14, 1848. He graduated at Bowdoin college in 1826, and studied law, but devoted himself to literature. In 1836 he visited England for his health, and spent two years there. His published works are: "Biography of North American Indians who have been distinguished as Orators, Statesmen, Warriors," &c. (2 vols. 18mo, New York, 1832); "Memoir of Phillis Wheatley" (Boston, 1834); "Traits of the Boston Tea Party" (1835); "Traits of Indian Manners, Character," &c. (2 vols. 18mo, 1835); and "Tales of the American Revolution" (1846).

**THAYER**, a S. E. county of Nebraska, bordering on Kansas, formed since 1870; area, 576 sq. m.; pop. in 1875, 2,139. It is intersected by the Little Blue river and Big Sandy creek, and is crossed in the N. part by the St. Joseph and Denver City railroad. It has an undulating prairie surface and a fertile soil. Capital, Hebron.

**THEATINES**, an order of regular clerks, founded at Rome in 1524 by Gaetano di Tiene (died in 1547; canonized by Clement X.), Bonifazio di Colle, Giovanni Pietro Caraffa (afterward Pope Paul IV.), and Paolo Consigliari. Gaetano and Bonifazio were the first who united to form a society of priests following the rules of apostolic life as set down in the New Tes-

tament; hence its members were popularly known as Cajetans (*Gaetani*). But the extension and establishment of the order were mainly due to Caraffa, who was archbishop of Chieti (Lat. *Theate*) when he was received by Gaetano as his associate, and thus gave the order its official name. It was approved in 1524 by Clement VII., under the designation of "regular clerks," the dress of the members being that of the secular clergy. Caraffa had been elected superior general. Their first residence on Monte Pincio was sacked by the Spaniards May 6, 1527, and Gaetano was subjected to the most cruel tortures to make him give up the riches he was thought to possess. He soon after retired to Venice with his companions, and was chosen superior, and he and they displayed extraordinary charity during the plague and famine of 1528. They were afterward united with the congregation of Somascha, founded about this time in a town of that name near Bergamo by St. Girolamo Emiliano. The two congregations were separated on the elevation of Caraffa to the papal chair, May 23, 1555. In 1547 they had only two establishments, one at Venice and another at Naples. Through the influence of Paul IV. they spread rapidly, and soon possessed four provinces in Italy, one in Germany, one in Spain, two establishments in Poland, one in Portugal, and one in Goa. In France they had only the Parisian residence, which produced several remarkable men. They also founded missions in Tartary, Tiflis, and Circassia. At the beginning of the present century the Theatines did not exist outside of Italy, where they had nine establishments. These were all suppressed in 1870.—There were also two communities of Theatine nuns (one a congregation of hermits), both founded by Ursula Benincasa, the one in 1583, the other in 1610. Neither had ever more than two establishments, and both are now extinct.

**THEATRE** (Gr. *θέατρον*, a seeing place, from *θεᾶσθαι*, to view), a building in which plays are represented. The first theatres of the Greeks, who were the founders of the drama in our sense of the word (see DRAMA), were exceedingly rude affairs. Thespis is said to have acted his plays in a wagon, and in the time of Æschylus the performances took place upon temporary wooden scaffolds, one of which having broken down during a representation in which Æschylus and Pratinas were rivals (about 500 B. C.), the Athenians in that year began to build the great theatre of Dionysus (Bacchus), the first permanent stone structure of the kind. It was probably used for dramatic purposes within a few years, though it was not finished until about 340; and in the mean time theatres had been erected in many parts of Greece, Asia Minor, and Sicily. The seats of the spectators, comprising the *θέατρον* proper, rose one above another in arcs of concentric circles, each row forming nearly two thirds of a circumference. The space immediately in front of the spectators, corresponding nearly to the modern pit or parquet, was called the orchestra, and was appropriated to the chorus. It was floored with boards, and in the centre of it stood the *θυμέλη* or altar of Bacchus, upon a raised platform which was sometimes occupied by the leader of the chorus, the police, the flute player, and the prompter; the last two were placed on the side next the stage, and concealed from the spectators by the altar. The stage was behind the orchestra and above it, and the chorus, whenever they had to take a part in the real action of the drama, ascended to it by steps. The back was closed by a wall called the *σκηνή* (Lat. *scena*); the whole space between the scena and the orchestra was known as the proscenium; and the part nearest the audience, where the actors stood when they spoke, was the *λογεῖον*. There was no scenery properly so called, but the scena was architecturally decorated and made to represent as far as possible the locality in which the action was going on. It had an entrance in the centre called the royal door, through which the principal characters made their appearance, and doors on the right and left for the subordinate personages. The plays of Æschylus and Euripides seem to require frequent changes of scene, but probably they were rather hinted at than actually made; they perhaps consisted merely in turning the *περίακτοι* (Lat. *versuræ*) or "wings," which were prism-shaped frames moving on pivots at each side of the proscenium. The whole stage was never concealed from the spectators; there is mention of a curtain, which instead of being drawn up was lowered through a crevice in the stage, but it covered only the background, or according to some authorities the wings. The machines for producing supernatural effects must have been numerous and elaborate, but are now imperfectly understood. They included the "Charonian steps," by which shades ascended from the lower world; the *μηχανή*, by which gods and heroes were represented passing through the air; and the *θεολογεῖον*, an elevated place above the scena, where the deities appeared in full majesty. Neither the stage, the orchestra, nor the auditorium was roofed, but there were porticoes running around the building, to which the people retreated in case of rain, and awnings were sometimes used to ward off the heat of the sun, for the performances always took place by daylight. The vast size of the ancient theatres, intended as they were to accommodate almost the entire population of a city at each performance, made it impossible for the unaided voice to be heard by the whole audience. Metallic vases were therefore placed under the seats to serve as reflectors of sound, and the actors wore masks with metallic mouthpieces to answer the purpose of speaking trumpets. The spectators were seated according to their rank. A price was charged for admission, at least until the performance was pretty far advanced; but in Athens from the time of Pericles the poorer class and subsequently all the

citizens were admitted at the cost of the public treasury. Women, it appears, were allowed to witness tragedies, but were excluded from comedies; boys were admitted to both. The actors were invariably males. The performances began early in the morning, and not unfrequently lasted 10 or 12 hours.—The Roman theatres were copied from those of the Italian Greeks. They were at first temporary structures of wood, which were sometimes extravagantly magnificent. One built by M. Æmilius Scaurus (58 B. C.) was capable of seating 80,000 people, and the scena was decorated with 3,000 statues and 360 columns in three stories, the lowest of white marble, the middle one of glass, and the uppermost of gilded wood. The first stone theatre was pulled down when nearly finished at the instance of P. Scipio Nasica (155 B. C.), on the score of public morality. In the Roman theatre women performed in interludes and mimics, but not in regular dramas. The orchestra was occupied by the senators, foreign ambassadors, and other distinguished persons. There was nothing corresponding to the θυμέλη or altar of Bacchus. The depth of the stage was proportionally greater than in the Greek theatre, being in the latter about one seventh of the diameter of the orchestra, and in the Roman one fourth. Thus, in the theatre of Bacchus at Athens the diameter of the orchestra (and consequently the width of the available part of the stage) was 72 ft., and the depth of the stage only a little more than 10 ft. A Roman stage of the same width would have been 17½ ft. deep. The following are some of the largest ancient theatres the ruins of which are now known:

| LOCATION. | General diameter, feet. | Diameter of orchestra, feet. |
|---|---|---|
| Ephesus | 660 | 240 |
| Tralles | 540 | 150 |
| Rome (theatre of Marcellus) | 517 | 172 |
| Miletus | 474 | 224 |
| Sparta | 453 | 217 |

—In the middle ages the only theatrical performances were the miracle plays, mysteries, and interludes. These were given for the most part in convents, colleges, and churches, or in the halls of palaces and castles. The first theatres in France were built for miracle plays. In 1548 the confraternity of the Trinity had a theatre in Paris in which they were licensed by the parliament to perform only "profane pieces of a lawful and honest character." So late as 1561 the French had no scenery, and the performers remained on the stage during the whole representation. The first Italian theatre is said to have been erected at Florence in 1581, by Bernardo Buontalenti, but it was probably not public. About the same time Palladio made an attempt to revive the classical theatre in the still existing *teatro Olimpico* at Vicenza, but with reduced proportions. From 1618, when a theatre was built at Parma by Aleotti, the modern arrangement began to prevail. By narrowing the stage opportunity was given for the use of painted scenery, and by increasing its depth for the introduction of a variety of complicated machines and the production of spectacular pieces.—In England there were regular companies of players as early as the reign of Edward IV., long before there were regular play houses. Churches, universities, private houses, and the yards of inns served at first for their performances. Probably the first play house was the London "Theatre," built before 1576; the Curtain in Shoreditch, and the theatres in Blackfriars and Whitefriars, were built near the same time. In Shakespeare's day London had three "private" and four "public" theatres, the difference between which is not clearly understood. His own plays were produced at the house in Blackfriars and at the Globe, both of which belonged to the same company, known as his majesty's servants. The Globe was a hexagonal wooden edifice, partly open at the top and partly thatched. In the middle was probably an uncovered court where the common people stood, and around three sides ran galleries or "scaffolds," under the lowest of which were enclosed boxes called "rooms." The prices of admission ranged from a penny or twopence to a shilling. The performance began at 3 o'clock; in the private theatres it took place by candle light. The stage at this period was strewed with rushes and concealed by curtains, which opened in the middle and drew backward and forward on an iron rod. In the background was a balcony or upper stage, likewise curtained, from which parts of the dialogue were spoken, and at each side of this balcony was a private box. In the private theatres the wits, critics, and other persons of consequence were furnished with seats on the stage. Movable scenery was first used in a regular drama in a public theatre by Davenant in 1662, though something of the sort had been arranged at Oxford by Inigo Jones as early as 1605, on the occasion of an entertainment given to James I. Shakespeare had no other scenery than tapestry hangings and curtains, but the use of stage machinery is as old as the drama itself. Women first appeared upon the English stage about the period of the restoration.—The first theatre in America was opened at Williamsburg, Va., Sept. 5, 1752. Others followed at Annapolis, Md., and in Nassau street, New York (1753), Albany (1769), Baltimore (1773), Charleston, S. C. (1774), Newbern, N. C. (1788), and Boston (1792). The largest in the United States are the opera houses of New York, New Orleans, Cincinnati, Philadelphia, and Brooklyn, and the Boston theatre. Modern theatres, except those intended for opera, are comparatively small. It has been found that the voice, moderately exerted, can be distinctly

heard about 90 ft. in front of the speaker, and 75 ft. each side. In an opera house the dimensions may be vastly increased, as singing can be heard at a greater distance than speaking, and it is not requisite to bring the audience near enough to see the facial expression of the performers. The theatres of New York are among the best in the world, and the seating arrangements of American theatres generally are more convenient than in foreign theatres. The opera houses and leading theatres in the United States are described in the articles devoted to the different cities. The best form for the auditorium is either three fourths of a circle, or a semicircle with divergent ends. The latter affords the best opportunities for seeing, but involves either a disproportionate and inconvenient width of stage, or a considerable useless space on each side of the proscenium. Most American theatres differ from those of Europe in having no private boxes, except a few on and adjoining the proscenium, by which means a vast gain is effected in the capacity of the house; they are also generally better lighted.—The largest and finest theatre in the world is the new Grand Opera of Paris. It was begun in 1860, and opened to the public for the first time on Jan. 5, 1875. It was built at the expense of the government, and cost $5,600,000, exclusive of the land which it occupies. Notwithstanding the vast size of the building, the auditorium contains only 2,194 seats, or about the same as the academies of music in New York and Brooklyn. By far the greater part of the building is occupied by a vast number of rooms, halls, staircases, shops, &c., appurtenances designed for the convenience and pleasure of the spectators and of those connected with the theatre. The stage is about 100 ft. in width by 220 ft. in depth, and 700 singers can be grouped upon it. In its facilities for ingress and egress, in the completeness of its machinery and appliances, and in the magnificence and costliness of its decorations, it far surpasses any theatre of modern times. The following are some of the largest theatres in the world, with the number of spectators they are capable of accommodating:

| | |
|---|---|
| London, New Pavilion, Whitechapel | 3,700 |
| " Drury Lane | 3,500 |
| " Her Majesty's, Haymarket | 2,500 |
| " Italian opera, Covent Garden | 2,000 |
| Milan, La Scala | 3,600 |
| Naples, San Carlo | 3,600 |
| Boston theatre | 3,400 |
| Venice, La Fenice | 3,000 |
| St. Petersburg, Bolshoi theatre | 3,000 |
| Philadelphia, academy of music | 2,850 |
| Turin, theatre royal | 2,500 |
| Florence, La Pergola | 2,500 |
| Munich, royal theatre | 2,500 |
| Brooklyn, academy of music | 2,243 |
| New York, academy of music (burned in 1866, and rebuilt smaller) | 2,160 |
| Paris, Grand Opéra | 2,194 |
| " Ambigu comique | 1,900 |
| " Porte St. Martin | 1,800 |
| " Théâtre Italien | 1,700 |
| " Théâtre Lyrique | 1,700 |
| " Odéon | 1,650 |
| " Opéra comique | 1,500 |

—In China every little village has its theatre, and each great town has several. They have no scenery and no auditorium, the spectators remaining in the open air. The expenses are defrayed sometimes by mandarins or other rich persons, but more frequently by associations formed for the purpose among the inhabitants of the neighborhood. The actors are generally strollers, and the female parts are played by young men or boys. In Japan the stage has scenery, the audience are furnished with seats, and women are allowed to perform.

**THEBAIS**, the ancient name of southern or Upper Egypt, from its capital Thebes. This division of the country extended from the islands of Elephantine and Philæ, near Syene (lat. 24° N.), to Thebaica Phylace, S. of Hermopolis Magna (about 27° 40′ N.).

**THEBES** (called No or No-Ammon by the Hebrews, and Diospolis the Great by the later Greeks and the Romans), anciently the capital of Upper Egypt, and for a long time, known as the period of the middle empire, of the whole country. Its Egyptian name was Ap, or Apé, and with the feminine article Tape, the head, which, being pronounced Thaba in the Memphitic dialect, was easily converted by the Greeks into Θῆβαι (Thebæ). Pliny and Juvenal, desiring to render its real name more closely, call it Thebe. From the fact that the names of the oldest kings appear only about Memphis, it is generally inferred that Thebes was not founded as early as the capital of Lower Egypt, though in antiquity it was reputed to be the oldest city in the world. It stood near the centre of the Thebaid, extending on both sides of the Nile to the mountain chains which enclose the valley. Strabo speaks of the vestiges of the city as extending 80 stadia (10 m.) in length. Diodorus estimated its circuit at 140 stadia or about 17 m., and Sir Gardner Wilkinson infers from its ruins that its length was 5¼ m. and its breadth 3 m. Its most flourishing period was that of the 18th dynasty; it began to decline about 800 B. C. (See EGYPT, vol. vi., p. 460.) Asshur-bani-pal pillaged it in the 7th century, and Cambyses in the 6th. After its destruction by Ptolemy Lathyrus (86 B. C.), it lost all its political and commercial importance, though it remained the sacerdotal capital of the worshippers of Ammon. The trade which had contributed to its prosperity had found new channels after the foundation of Alexandria; and as the capital of a Macedonian and Roman prefecture it took little part in the affairs of Egypt. It was desolated successively by Christians of the Thebaid, in their zeal against idolatrous monuments, by barbarians from Arabia and Nubia, and by the Saracens; after whose invasion its name scarcely occurs for many centuries.—The ruins of Thebes, which are among the most magnificent in the world, are found at the modern villages of Luxor and Karnak on the E. bank of the Nile, and Gurna and Medinet-Abu on the western. The eastern quarter of the ancient city contained the mass

of the population, while the western side was covered with temples and palaces and their avenues of sphinxes, and with the rock-hewn tombs of the kings. The principal structures at Gurna are the palace temples Mernephtheum and Ramesseum. The former, approached by an avenue 128 ft. long, has pillars in the oldest style of Egyptian architecture and remarkable bass-reliefs. The latter, which for symmetry of architecture and elegance of sculpture may vie with any other Egyptian monument, occupies a series of terraces communicating with each other by flights of steps. It is supposed to be the Memnonium of Strabo, and that he corrupted Miamun, the title of Rameses II., into Memnon. Its entrance is flanked by two pyramidal towers; its first court has a double avenue of columns on either side, and in the area a pedestal on which was a syenite sitting colossus of Rameses; its second court has walls covered with sculptures representing the wars of Rameses III., and Osiride pillars which are doubtless the monolithal figures 16 cubits high described by Diodorus; the third stairway, from the foot of which Belzoni took the head of a royal statue of red granite, now in the British museum and known as the young Memnon, conducts to a hall for public assemblies, with columns and walls covered with civil and religious sculptures; and beyond the hall extended nine smaller apartments, two of which remain, supported by columns, one of them being the sacred library or "dispensary of the mind" mentioned by Diodorus. Among the other monuments in this vicinity are two colossal statues, with the pedestals about 60 ft. high, the wonder of the ancients, one of them known as the vocal Memnon. (See Memnon.) The village of Medinet-Abu stands upon a lofty mound formed by the ruins of the most splendid temple palace in western Thebes, the Thothmesium, connected with the palace of Rameses by a dromos 265 ft. long. The sculptures in the latter are of singular interest, being the only examples that have been found of the decoration of the private apartments of an Egyptian palace. The whole sweep of the Libyan hills, for the space of 5 m. and to the height of 300 ft. from Gurna to Medinet-Abu, is full of sepulchres, excavated in the native calcareous rock. This was the necropolis of the whole city, no tombs existing on the eastern side. The mummies are laid in rows by the side of or in tiers above each other, but never stand erect. The tombs of the lower classes are unsculptured, but abound in mummies of sacred animals. The royal sepulchres are in the valley of Bab el-Muluk, or Biban el-Muluk (the gate or gates of kings), the most spacious and highly adorned belonging to those monarchs who enjoyed a long reign. The tombs near the entrance of the gorge belong entirely to the 19th and 20th dynasties, and those in a branch path are of the 18th dynasty. The monuments, as also those in the separate burial place allotted to the queens, are chiefly interesting from their inscriptions.—Still more remarkable are the ruins on the E. bank of the river, in the villages of Luxor and Karnak. At Luxor the most striking monuments were

Gateway of the Temple of Luxor.

two beautiful obelisks of red granite, covered with inscriptions, one of which has been removed to the Place de la Concorde in Paris. In the rear are two sitting statues of Rameses,

Gateway of Karnak.

one 39 ft. high, but now covered to the breast with accumulations of earth and sand. Two courts and a series of apartments, connected and surrounded by colonnades and porticoes,

extend beyond. The road from Luxor to Karnak lies through fields of *halfa* grass, though they were once united by an avenue of androsphinxes. The great palace temple of Karnak stands within a circuit wall of brick, the enclosure being 1,800 ft. long and somewhat less broad. It was approached by an avenue of crio-sphinxes, of which only fragments remain. Between the end of the dromos and the main body of the building, five lofty pylones and four spacious courts intervene. In the first court were two obelisks of Thothmes I., one of which still remains; in the second court is another obelisk, the loftiest known except that of St. John Lateran at Rome; and in one of the chambers are the sculptures which compose the Karnak tablet, called the "hall of the ancestors" or the "tablet of Tuthmosis" (Thothmes III.), now in the Louvre. The king is represented on it as making offerings before the images of 61 of his predecessors. In the British museum is now a tablet of the same kind, known as the "tablet of Abydos." The great hall is 80 ft. high, 329 ft. long, and 179 ft. wide; the roof is supported by a central avenue of 12 massive columns, 66 ft. high and 12 ft. in diameter, together with 122 columns of less gigantic dimensions. These vast courts, halls, and esplanades were reared by kings of the 18th and succeeding dynasties for purposes partly religious and partly secular. The sacred calendar abounded in days for periodical meetings; the troops were reviewed and the spoils of victory apportioned in the courts of royal palaces, which also served for the administration of justice and occasionally for the encampment of the army.

**THEBES** (Gr. Θῆβαι; Lat. *Thebæ;* modern Gr. *Thiva*), in Greek antiquity, the chief city of Bœotia, built on and around a hill between the streams of Ismenus on the east and Dirce on the west. The citadel occupied the height, and the greater part of the town stood in the valleys. Of its ancient buildings, monuments, and walls, only a few scattered fragments remain, and its topography is entirely uncertain. It is impossible to harmonize the ancient writers as to the position or even the names of its seven gates. Thebes was equally illustrious in the mythical and the historical ages of Greece. Its two sieges and the fortunes of its royal houses were favorite subjects of tragedy; and it was for a time the ruling city of Greece. Tradition ascribed to Cadmus the foundation of the city, which was hence called Cadmea, a name afterward restricted to the citadel. From the five Sparti, the survivors of the progeny of the dragon's teeth, the noblest Theban families claimed descent. The expulsion of Œdipus, and the successive sieges by the "Seven against Thebes" and by the Epigoni, were the principal recorded events before the Cadmeans were driven out by the Bœotians, a tribe from Thessaly. This occurred about 60 years after the Trojan war, according to Thucydides. The legislation of Philolaus, in the 8th century B. C., gave it an oligarchical instead of monarchical form of government, and made it the head of the confederacy of Bœotian towns. The first entirely certain event in its history is the revolt of one of these towns, Platæa (about 519), which applied to Athens for protection. A war ensued between the Thebans and Athenians, in which the latter were successful, and which initiated lasting enmity between the two states. Thebes lost credit by abandoning the cause of Greece in the Persian war, and fighting against the Athenians at Platæa (479). The victorious Greeks appeared before its walls, and compelled the inhabitants to surrender their "Medizing" leaders, who were immediately put to death. An Athenian invasion supplanted its oligarchy by a democratic government in 456, but in 447 the exiled aristocratic leaders returned, defeated the Athenians, and reëstablished the former government. During the Peloponnesian war the Thebans were more anti-Athenian than even the Spartans, but they joined the coalition against the latter in 395, and were the only portion of the allied army which was not routed by them at Coronea. The peace of Antalcidas (387) deprived them of their supremacy over the other Bœotian towns. The Spartans, who treacherously seized the citadel in 382, were expelled by Pelopidas about the close of 379, and were defeated by Epaminondas at Leuctra in 371. Epaminondas invaded the Peloponnesus, and established there the Arcadian confederation and the state of Messenia as political powers antagonistic to Sparta. But the Thebans sought in vain to establish their supremacy by a general treaty, and lost it after the death of Epaminondas at Mantinea (362). In 358 Athens wrested Eubœa from Thebes. In the sacred war (357-346) the Thebans were opposed to Athens and Sparta, and received support from Philip of Macedon; but when the design of the latter to conquer the whole of Greece became apparent, they joined the Athenians against him. Philip, however, was victorious at Cheronæa (338). Thebes received a Macedonian garrison, and its leading citizens were put to death or banished. Alexander the Great razed it to the ground in 335, sparing only the house of Pindar, after which it never again formed an independent state. Cassander restored the city in 315, and it was taken by Demetrius Poliorcetes in 292 and 290. In the time of Strabo it had dwindled down to the condition of a village, but it was a flourishing town during the 10th and 11th centuries. It was plundered by the Normans of Sicily in 1146. The present town is small and poor.

**THEFT.** See Larceny.

**THEINE.** See Caffeine, and Tea.

**THEINER. I. Augustin**, a German historian, born in Breslau, April 11, 1804, died in Civitâ Vecchia, Aug. 9, 1874. He studied at Breslau and Halle, and from 1826 to 1828 assisted his brother Johann Anton in his work on the history of celibacy. An essay on the papal decre-

tals procured for him from the university of Halle the degree of doctor of laws, and from the Prussian government a stipend for a literary journey to Vienna, London, and Paris. In 1831 he visited Rome, and became a member of the oratory of St. Philip Neri, professing thenceforward an ultramontanism as extreme as had been his Gallicanism. He continued to reside in Rome, and was consultor of the holy office, of the congregation of bishops and regulars, and of the division of the propaganda on oriental rites. In 1848 he published *Lettere historico-critiche intorno alle "Cinque piaghe della santa chiesa" del chiarissimo D. Antonio Rosmini Serbati.* In this work Theiner denounced the election by laymen of bishops and parish priests, and maintained that the temporal sovereignty of the popes was "indispensable, under the modern formation of society, to the spiritual independence of the supreme pastor of the church." It was translated into Latin (Naples, 1849). Being appointed prefect or keeper of the secret archives of the Vatican in 1851, he issued in succession various compilations therefrom illustrating the ecclesiastical history of nearly all the different Christian nations. Six folio works were printed in the Vatican. He also began in 1856 a continuation of the *Annales Ecclesiastici* of Baronius, of which 3 vols. fol. have appeared, and an edition of the original work to consist of about 60 vols. 4to, of which 15 had appeared in 1868 (Bar-le-Duc). In 1853, in answer to Crétineau-Joly's history of the suppression of the Jesuits, he published *Geschichte des Pontificats Clemens XIV.* (2 vols., Leipsic and Paris), which led to a long and bitter pamphlet controversy. In 1861 he began a documentary history of the pope's temporal dominion, extending from 756 to 1793, entitled *Codex Diplomaticus Dominii temporalis Sanctæ Sedis* (3 vols. fol., Rome, 1861–'3). This was followed by a smaller work in 1864 destined to answer Passaglia's appeal to the Italian bishops, and maintaining the necessity of the temporal power from the declarations of the councils of Lyons (1245) and Constance. At the approach of the Vatican council in 1869, Theiner entered into a correspondence with Dr. Döllinger and Prof. Friedrich, in which he advocated the Old Catholic doctrine and position. The discovery of this caused him to be debarred all access to the archives, while, in consideration of his age, he was permitted to retain his salary and his apartment in the Vatican. In 1874 Theiner visited Austria to make arrangements for publishing another important literary work, and on his return to Italy died suddenly at the seaside, the pope having sent him his forgiveness and blessing on hearing of his danger. His other works include *Geschichte der geistlichen Bildungsanstalten* (Mentz, 1835); *Versuche des heiligen Stuhls die Völker des Nordens wiederum mit der Kirche zu vereinen* (Augsburg, 1837); and *Die neuesten Zustände der katholischen Kirche beider Ritus in Polen und Russland seit Katharina II.* (Augsburg, 1841). **II. Johann Anton**, a German theologian, elder brother of the preceding, born in Breslau, Dec. 15, 1799, died there, May 15, 1860. He studied Roman Catholic theology at Breslau, and was appointed there in 1824 professor of Scriptural exegesis and canon law. He was from the beginning a zealous advocate of Gallican principles, and eagerly sought to have them introduced and carried out among the clergy of Silesia. Assisted by his brother Augustin, he published in 1826 an extensive work on the history of celibacy (*Die Einführung der erzwungenen Ehelosigkeit*, Altenburg, 1828; new ed., 1845). He resigned his chair in 1830, and held a pastoral charge till 1845, when he joined the German Catholics, publishing in vindication of this step *Die reformatorischen Bestrebungen in der katholischen Kirche* (Altenburg, 1845); but soon afterward he joined the Protestant church, and received an appointment in the library of the university of Breslau. He wrote a commentary on the minor prophets, forming part of the *Bibelwerk* of Dereser, and *Das Seligkeitsdogma der römisch-katholischen Kirche* (Breslau, 1847).

**THEISS** (anc. *Tibiscus;* Hun. *Tisza*), a river of Hungary, which rises in the northeast, in the county of Mármaros, flows westward to Tokay, thence S. W. to Szolnok, when it turns S. and enters the Danube S. of Titel, near the southern boundary of Hungary. Its length is upward of 600 m., for most of which it is navigable. Its principal tributaries are the Bodrog, Hernád, Sajó, and Zagyva on the right, and the Szamos, Körös, and Maros on the left. Its lower course for nearly 300 m. is parallel to the Danube, and about the beginning of the present century the Francis canal was dug from one river to the other, which shortens the route down the Theiss and up the Danube 106 m. The canal has been enlarged, and a branch canal from Sztapár to Neusatz on the Danube, completed in 1875, passes through one of the most fertile districts in southern Hungary. Among the principal towns on the banks of the Theiss are Csongrád, Szegedin, Zenta, and Old Becse.

**THELWALL, John**, an English author, born in London, July 27, 1764, died in Bath, Feb. 17, 1834. In his 22d year he abandoned the profession of law for literature. In 1787 he published "Poems" (2 vols.); and embracing liberal opinions, he became a member of the "Corresponding Society." Taking a prominent part in the political agitation of the times, he was prosecuted for high treason along with John Horne Tooke and Thomas Hardy, and after a trial of five days was acquitted. He afterward lectured on political subjects, and in 1801 began to act as tutor of elocution. His works include "The Peripatetic" (3 vols. 12mo, 1793); "The Tribune" (3 vols. 8vo, 1796); "Poems, with Memoir of his Life" (1802); "The Daughter of Adoption," a novel; essays on the treatment of im-

perfections in speech, &c.—His son Algernon Sydney (1795–1863), a clergyman of the established church and teacher of elocution, published religious works, "Iniquities of the Opium Trade" (1839), &c.

**THEMIS,** in the Greek mythology, a daughter of Uranus and Gæa, married to Zeus. She dwelt in Olympus, and convened the assembly of the gods. She is represented in Homer as the personification of the order of things established by law, custom, and equity. At Thebes she had a sanctuary in common with Zeus Agoræus, and at Olympia in common with the Horæ, her daughters.

**THEMISTOCLES,** an Athenian general, born about 514 B. C., died in Magnesia, Asia Minor, about 449. He took part in the battle of Marathon in 490. After the exile of Aristides in 483 Themistocles was the great political leader in Athens. His main endeavor was to make Athens a great naval power, and to prepare it to resist the inroads of the Persians. In the beginning of 480, when the force of Xerxes was on the point of passing the Hellespont, he and the Spartan Euænetus were in command at the defile of Tempe, which they abandoned on finding that troops could be landed in their rear, retreating to their ships. Afterward he took charge of the Athenian portion of the fleet stationed at Artemisium. When the vast number of Persian ships was discovered, the Spartans were disposed to draw back to the Peloponnesus; but the Eubœans gave 30 talents to Themistocles, with which he induced them to remain and defend Eubœa. In the ensuing battle the Greeks had the advantage; but the Athenian ships being much crippled, it was determined to retire. (See Greece, vol. viii., p. 190.) At the instance of Themistocles the Athenians abandoned their city, and removed mainly to Salamis, where the whole naval force of Greece was gathered. It was only by his influence and devices that the fleet was kept together, and the naval battle was fought which resulted in a complete victory for the Greeks. The Athenians were desirous of pushing on to the Hellespont to prevent the retreat of Xerxes, but their confederates refused. Herodotus says that Themistocles privately sent word to the king that he had restrained the Greeks from pursuing his ships and breaking up his bridges over the Hellespont; and that he did this in order to induce Xerxes to return, and for the purpose of securing for himself a safe retreat in case any mischance should befall him at Athens. Modern historians consider this highly improbable. After the division of the booty gained at Salamis, the Greeks sailed to the isthmus, where Themistocles, though deprived of the first prize for skill and wisdom by each of the commanders voting for himself, was declared the wisest man in Greece, and the whole country was filled with his fame. He was received in Sparta with unprecedented honors; and though the Lacedæmonians gave to Eurybiades the crown of valor, they gave to Themistocles the crown of wisdom. When the Athenians returned to their city, the Spartans opposed their rebuilding their fortifications on an enlarged scale; but Themistocles was sent to them as ambassador, and he contrived to deceive them until the walls were far enough advanced to be in a state of defence. Athens was now secure against external enemies, and Themistocles was more than ever desirous of making her a great maritime power. The work on the Piræus was resumed on a far grander scale, and by his advice the three harbors were enclosed by a wall nearly seven miles in circuit. He also persuaded the Athenians to add 20 triremes to their navy every year. His political ascendancy soon declined. His opponents in Athens were headed by Cimon, son of Miltiades, and by Alcmæon. He was acquitted of treasonable intercourse with the Persians, but about 471 was ostracized and went into exile at Argos. According to some versions, Themistocles was accused by the Lacedæmonians of sharing the treasons of Pausanias; but he, having notice of his impending arrest, fled to Susa, where he addressed to Artaxerxes, the son of Xerxes, a letter claiming protection on the score of his services to his father after the battle of Salamis, and asking permission to wait a year and then to come before him in person to explain his views. His request was granted. At the end of a year, having mastered the Persian language, he entered into personal communication with the king; and no Greek, says Thucydides, had ever before attained such a commanding influence and position at the Persian court. He excited Artaxerxes with plans for the subjugation of Greece, and was presented by him with a Persian wife and with large presents. After having visited various parts of Asia, he lived at Magnesia on the Mæander, and received his maintenance from the revenues of that and two other cities. Some of his property at Athens was secretly sent him by his friends, but the bulk of it, amounting to 80 or 100 talents, was confiscated. He is said to have poisoned himself because he knew his promises to the Persian king could not be fulfilled. This is perhaps the most popular form of the story, of which other versions relate that the Persian king had set a price of 200 talents upon his head, that he went to Susa in the disguise of a stranger for the king's harem, and that he was actually put on trial to answer the accusations of Mandane, the sister of Xerxes, for the loss of her sons who fell at Salamis. We have no contemporary history of the life of Themistocles, and when Thucydides wrote his history his enemies had done their best to heighten prejudice against him. His life was written by Nepos and by Plutarch.

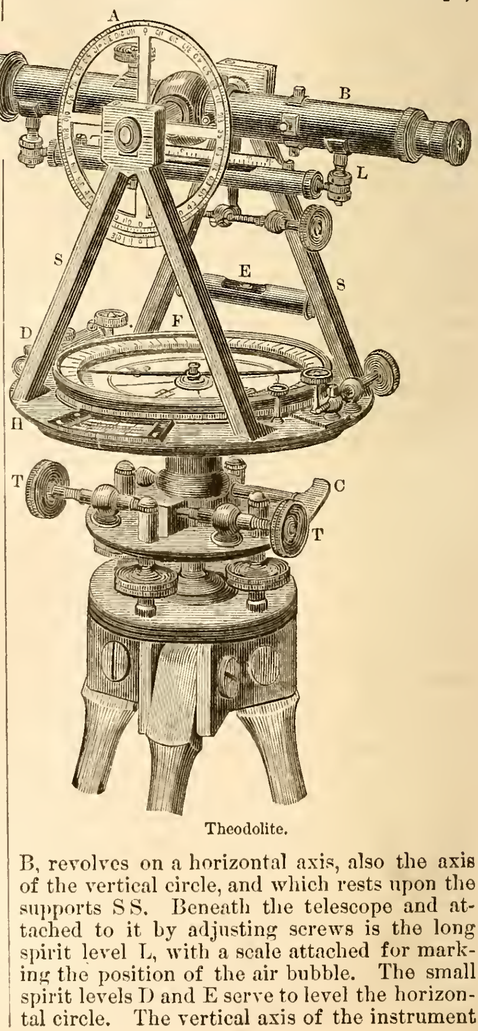
**THÉNARD, Louis Jacques,** baron, a French chemist, born at La Louptière, Champagne, May 4, 1777, died in Paris, June 21, 1857. He studied

chemistry in Paris under Vauquelin and Fourcroy, in 1798 became a teacher of that science in the polytechnic school, in 1804 professor in the collége de France and the Sorbonne as successor of Vauquelin, and in 1810 also in the polytechnic school. In the latter year he was elected a member of the academy in place of Fourcroy. Charles X. on his accession to the throne made him a baron, and under Louis Philippe he was created a peer in 1832, and in 1838 director of the collége de France. He was president of the society for the encouragement of national industry, and founded a society for the benefit of inventors impoverished by useful researches. His most popular work, *Traité élémentaire de chimie théorique et pratique* (4 vols. 8vo, 1813–'16; 7th ed., 5 vols., 1836), has been translated into several languages.

**THEOBALD, Lewis,** an English author, born at Sittingbourne, Kent, died in September, 1744. He was an attorney, but did not practise. His tragedy "Electra" appeared in 1714; and in 1717 he contributed to Mist's "Weekly Journal" papers under the title of "The Censor," which provoked attacks from other writers, one of whom was Dennis. He published a pamphlet entitled "Shakespeare Restored, or a Specimen of the many Errors as well committed as unamended by Mr. Pope in his Edition of this Poet, designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever yet published" (4to, London, 1726). For this Pope made him the hero of the "Dunciad." (See Pope, Alexander, vol. xiii., p. 709.) Theobald then brought out an edition of Shakespeare's works (7 vols. 8vo, 1733), which destroyed the reputation of Pope's edition. Theobald wrote or translated 20 plays, now all forgotten, and also brought on the stage a play entitled "The Double Falsehood, or the Distrest Lovers," the greater part of which he asserted was composed by Shakespeare. He also published a life of Sir Walter Raleigh.

**THEOCRITUS,** a Greek poet, born in Syracuse, who flourished about 270 B. C. He went to Alexandria, and secured the favor of Ptolemy Philadelphus, but returned to Syracuse during the reign of Hiero II. He wrote in a mixed dialect in which the Doric predominated, and was the creator of pastoral poetry as a department of literature. There are extant 30 poems, called by the general name of "Idyls," which are attributed to him, and 22 epigrams. He had several imitators, of whom the greatest was Virgil. The first edition, containing only 18 idyls, appeared at Milan probably in 1493, and the Aldine edition in 1495. Among the more important subsequent editions are those of Reiske (2 vols., Leipsic, 1765–'6), Warton (Oxford, 1770), and Paley (Cambridge, 1863). The principal English translations of the poems are those of Creech (London, 1681), Fawkes (1767), Polwhele (1786), Chapman (1836), and Calverly (1869).

**THEODOLITE,** a surveying instrument for measuring vertical and horizontal angles and taking levels, combining the uses of the ordinary transit, the quadrant, and the level. In the American form of the instrument, the telescope turns over and the vertical angles are read on a graduated circle. In the English form the vertical angles are read on a semicircle beneath the telescope and level; the telescope cannot therefore turn over, but is reversible. The American form is preferable by reason of the greater facility and precision of the adjustments. In common with all such kinds of instruments, it is made of brass. The principal parts are the vertical circle A and the horizontal circle F, which rests upon the plate H. A magnetic needle also rests upon the horizontal plate, which may be used when desired for ascertaining the earth's meridian or the deviation of a line from it. The telescope,



Theodolite.

B, revolves on a horizontal axis, also the axis of the vertical circle, and which rests upon the supports S S. Beneath the telescope and attached to it by adjusting screws is the long spirit level L, with a scale attached for marking the position of the air bubble. The small spirit levels D and E serve to level the horizontal circle. The vertical axis of the instrument

is held by a socket in the plate immediately above the tripod, and is furnished with a clamp C, and slow-motion screws T T. The horizontal circle revolves upon the plate H, upon which there is a vernier the divisions of which are sometimes read by means of an attached microscope, although it is preferable to employ a pocket microscope for the purpose. The vertical circle is also supplied with a vernier, and both circles have clamps and slow-motion screws. It is evident that if the vernier of the vertical circle in the adjusted instrument reads zero when the telescope is level, and then is moved through an arc of 30° to bring the cross hairs upon an object, such object will have an elevation of 30° above the point of observation; and also that if the horizontal circle is moved through an arc of any number of degrees to bring the cross hairs of the telescope from one object to another, the lines passing through such objects will make corresponding angles with each other at the point of observation. When used for important surveys the circles are 30 in. or more in diameter; in the smaller instruments they are 5 or 6 in.—See Gillespie's "Treatise on Levelling, Topography, and Higher Surveying" (new ed., New York, 1875).

**THEODORA.** See Justinian.

**THEODORE,** king of Abyssinia. See Abyssinia, vol. i., p. 46.

**THEODORET** (Theodoretus), a Syrian theologian, born at Antioch probably in 393, died in 457 or 458. He was of a noble family, entered a cloister, became in 423 bishop of Cyrrhus on the Euphrates, and reunited many members of the sects with the orthodox church. He declared against the Nestorians, and at the council of Chalcedon, in 451, subscribed the condemnatory decree against Nestorius. He is esteemed as an exegetical writer (see Richter, *De Theodoreto Epistolarum Paulinarum Interprete*, Leipsic, 1822), and he also wrote homilies, a history of the Christian church from 324 to 429, an epitome of heretical fables, the lives of 30 hermits, and various other works, including 180 letters. Collective editions of his works have been edited by Sirmond (4 vols., Paris, 1642; supplement by Garnier, 1684), and by J. L. Schulze and Nösselt (10 parts, Halle, 1769-'74), and in Migne's *Patrologie grecque*, vols. xli., xlii., and xliii. A translation of his "Ecclesiastical History" was published in Bohn's "Ecclesiastical Library" (1854).

**THEODORIC** (Ger. *Dietrich*), surnamed the Great, king of the Ostrogoths, born in Pannonia about 455, died in 526. He was the son of Theodemir, one of the chiefs of the Ostrogoths settled on the banks of the Danube, and when eight years old was sent as a hostage to the court of Constantinople. At the age of 18 he was restored to his father, and, after greatly distinguishing himself in war, he succeeded him as sole king of the Ostrogoths in 475. The southern part of Pannonia and Dacia had previously been ceded to them by the emperor Zeno the Isaurian, of whom Theodoric was for some years a faithful ally; but the emperor broke his promises, and Theodoric ravaged the Byzantine territories till 483, when Zeno conferred upon him large gifts and many honors, and in 484 he named him consul. The war was renewed in 487, and Theodoric marched upon Constantinople; and to get rid of him Zeno proposed to him the invasion of Italy, then ruled by the usurper Odoacer. Consequently in 488 he marched toward the peninsula at the head of his whole people, amounting to about 200,000, with a large number of wagons. He first met in the Alpine passes and routed an army of Gepidæ and Sarmatians, then defeated Odoacer himself on the banks of the Sontius (Isonzo) in 489. After two other victories, one on the banks of the Adige and the other on those of the Adda, he shut his opponent within the walls of Ravenna, and after a siege of three years received his capitulation in 493, apparently consenting to share the kingdom of Italy with him; but Theodoric soon after had his rival assassinated at a solemn banquet, and firmly established his power over the whole peninsula. He distributed one third of the lands to his soldiers in military tenures, but preserved as far as possible the administrative organization of the Roman empire. Under his fostering care Italy became prosperous again; agriculture and industry revived; literature and the fine arts flourished; internal improvements went on, and new monuments were erected. Through well devised alliances, he controlled nearly all the barbarians that had settled in western Europe. He checked the triumphant progress of Clovis after the victory of Vouillé in 507, protected the Visigoths, and secured for himself the possession of Provence. His latter years were embittered by religious troubles. The Arians, to which sect he belonged, being persecuted in the East, he retaliated against the Catholics of Italy; this brought on a conspiracy, in which the philosopher Boëthius, a great favorite with him, and the venerable Symmachus were apparently involved, and in a moment of passion he ordered them to be put to death. Their innocence being afterward demonstrated, remorse preyed upon his mind and hastened his death. He is the Dietrich of Bern of the *Nibelungenlied*.

**THEODOSIA,** or **Feodosia.** See Kaffa.

**THEODOSIUS,** a Roman general, beheaded in Carthage, A. D. 376. During the reign of Valentinian he was sent to the defence of Britain, in 367 crossed the channel at the head of a large army, and in two campaigns freed the country from the barbarians, strengthened the fortifications, and confirmed the Roman power. In 370 he returned, was made master general of the cavalry, and was stationed on the upper Danube, where he defeated the Alemanni. When in 372 Firmus, a Moor, had made himself master of Mauritania and Numidia, and Count Romanus, the governor of Africa, unable to oppose, had joined him in rebellion, Theodosius was sent to that province to reduce

it to its allegiance. At the head of a small body of men, he advanced into the heart of an unknown and hostile country, driving his enemy before him, until at last the usurper fled to Igmazen, king of the Isaflenses. The latter being threatened with destruction for harboring him, Firmus strangled himself. Theodosius recovered Africa, but for some unassigned reason, probably because his name and services were too great for a subject, he was put to death. From him descended a line of Roman emperors.

**THEODOSIUS I., the Great,** a Roman emperor, son of the preceding, born in Italica or Cauca, Spain, about A. D. 346, died in Milan, Jan. 17, 395. He learned the art of war under his father, was early given a separate command and appointed duke of Mœsia, and in 374 gained a victory over the Sarmatians. After the execution of his father he retired to Spain, where he led a private life until the emperor Gratian summoned him to take the supreme command, declared him Augustus, Jan. 19, 379, and assigned to him the administration of Thrace, Asia, and Egypt, with Dacia and Macedonia. Fixing his headquarters at Thessalonica, Theodosius carried on the war against the Goths during four campaigns (379–382). The Goths, divided by dissensions and jealousies after the death of their leader Fritigern, were again united under Athanaric, who made peace and visited Constantinople, where he died; and the magnificent funeral honors paid him by Theodosius so won over his followers that they enlisted in the Roman army. In 383 Gratian, the emperor of the West, was dethroned and put to death by Maximus, and Theodosius entered into a treaty with the usurper, by which he recognized him as emperor of the countries north of the Alps, Valentinian, the brother of Gratian, being secured the possession of Italy, Africa, and western Illyricum. Theodosius now devoted his attention to the affairs of the church. Fixing his residence at Constantinople, the stronghold of Arianism, he determined to do away with that creed, and gave to the archbishop Demophilus the alternative of subscribing to the Nicene creed or instantly resigning. Demophilus resigned, and Gregory Nazianzen was installed in his place. Six weeks afterward Theodosius commissioned his lieutenant Sapor to expel all the Arian clergy from the churches in his dominions, and gave him a military force sufficient to carry out the decree. In May, 381, he assembled the first council of Constantinople, to confirm and complete the Nicene creed; and during 15 years he issued at least 15 edicts against all heretics, especially against those disbelieving the doctrine of the Trinity. In the mean time Maximus had entered Italy, and dethroned Valentinian II. Theodosius, who had married a sister of Valentinian, marched against Maximus, then encamped at the Pannonian city of Siscia (now Sissek) on the Save, defeated him, and pursued him to Aquileia, where Maximus was given up by his own troops and put to death. Theodosius entered Rome in triumph, June 13, 389. The people of Thessalonica having for a slight cause murdered Botheric and the other principal officers of the little garrison, the emperor sent thither an army of barbarians, who, when the inhabitants were assembled by invitation at the circus, massacred them to the number of many thousands. For this St. Ambrose forbade him to enter a church in Milan until he had done public penance. He remained in Italy three years. When Valentinian was strangled in 392 by his general Arbogastes, who had secured for himself all the real power of the government, and now set up as emperor the rhetorician Eugenius, Theodosius undertook again the conquest of the West. After a severe and long uncertain contest he defeated Arbogastes near the passes of the Julian Alps. Theodosius was now master of the whole Roman world. Honorius, his younger son, was called to Milan to receive the sceptre of the West, and here Theodosius died immediately after his arrival. In the eastern empire he was succeeded by his elder son Arcadius.

**THEOGNIS,** a Greek elegiac poet, who flourished about 540 B. C. He was a citizen of Megara; and as in the contests between the aristocratic and democratic parties he belonged to the former, he shared in their defeat, and went into exile at Thebes. He visited Sicily, Eubœa, and Sparta, and survived the Persian war of 490. He is the author of numerous elegies, originally comprising 2,800 verses, of which 1,389 are extant. They discuss oligarchical education and the humanities. The best editions are Welcker's (Frankfort, 1826) and Bergk's in *Poetæ Lyrici Græci* (3d ed., Leipsic, 1866).

**THEOLOGY** (Gr. θεός, God, and λόγος, discourse), the science which treats of God and divine things. The name *theologos* was given by the Greeks to the authors of theogonies (as Orpheus and Hesiod), and to those who wrote poems (as Empedocles) or philosophical treatises (as Pherecydes) on divine things and the origin of things through the gods. A distinction was early made, as by Varro, between "mythical theology," a knowledge of the myths and legends concerning the deities in the classic poets; "physical theology," the investigations of philosophers on the origin of the world; and "civil theology," a knowledge of public worship. The ecclesiastical writers of the 3d and 4th centuries used the word, but applied it only to doctrinal treatises on the nature of the Godhead, or on the Trinity. Somewhat later the term was used by Theodoret, Maximus, and others, of the aggregate doctrines of the Bible, but its most common signification remained the doctrine of God. Abélard was the first to apply the term to the entire science of the Christian religion, which signification it has since retained. With regard to the sources from which theology derives its contents, it is common to divide it into natural or philosophical theology, which confines itself

to the development of the religious ideas resting on rational arguments only, and positive or revealed theology, which sets forth and systematizes the doctrines of the Scriptures and of the church. Revealed theology or Biblical theology is occupied solely with the investigation and representation of the doctrines contained in the Bible. A distinction is made between theoretical theology or dogmatics and practical theology or ethics. Theology, viewed as the whole of religious science, is commonly regarded as consisting of four main branches, historical, exegetical, systematic, and practical or moral theology. These are again variously subdivided, and several auxiliary sciences are connected with them. Thus historical theology embraces the history of the church, of Christian doctrines, of heresies, of councils, &c. To exegetical theology belong the interpretation (exegesis) of the Bible; hermeneutics, the science which teaches the right principles to be observed in interpreting the Bible; criticism, which investigates and tries to establish the genuine original text; the introduction to the Bible, which discusses the time when and place where each book of the Bible originated, its authenticity, and kindred questions. Systematic theology, also called merely theology, comprises the system of Christian doctrines (dogmatics); the system of Christian ethics; symbolics, the comparative statement of the doctrines of the several religious denominations, &c. Practical theology includes homiletics, catechetics, liturgics, ecclesiastical law, &c. Polemics and apologetics, which are also often treated as separate branches of theology, belong to several of the above four principal divisions at the same time.—Until the time of Abélard little attention was paid to comprehending theology in its totality, and to establishing the connection of the branches with each other. Although nearly all the theologians of the middle ages whose writings are extant belonged to the same church, yet they were divided into two fundamentally different schools, the scholastics and mystics. The theologians of the churches which grew out of the reformation of the 16th century followed, in their treatment of theology, either the scholastics or mystics, though the name of the former was discarded both by their Protestant and Roman Catholic followers. A new era in the history of theology was inaugurated by the philosophy of Kant, who fully developed and systematized a new theory of Christian theology, commonly called rationalism, which more or less made the belief in a religious doctrine dependent on its demonstrability by reason. This view gained the ascendancy in several Protestant churches. Its opponents, who defended the Bible as the absolute rule of faith, were called supranaturalists, and the subsequent history of theology is a contest not yet ended between these two systems. The chief arena of this controversy has been Germany; but it has had little or no influence over Roman Catholic schools. It has also been attempted to build up theological systems in opposition to Christianity, such as deism and pantheism.—In Roman Catholic schools, theology is divided into dogmatic and moral. Dogmatic theology, considered in its various methods of exposition and demonstration, is termed positive theology when it bases its proofs on Scripture and tradition. Moral theology treats of divine and human law as the rule of our actions. It aims at determining the true sense of the decalogue and the gospel precepts, discusses virtues and vices, examines the principles of justice and the foundations of injustice, points out what is needful and unlawful, and teaches all Christians their respective obligations in all states, conditions, and offices. Moral theologians are often called casuists, from their treating *ex professo* of "cases of conscience." Scholastic theology is that peculiar method introduced into the schools during the 11th and 12th centuries. It reduced all doctrinal matters into one body, so coördinating them that one question explained and completed another, binding them into a connected and systematic whole; it observed in its every demonstration the strict process of syllogistic reasoning, making use of the admitted principles of metaphysics, and thus conciliating faith with reason, and religion with philosophy.—Valuable systematic works, giving a survey of the entire field of Christian theology, have been published by President Dwight, Dr. J. Pye Smith, Prof. Hodge ("Systematic Theology," 3 vols. 8vo, New York, 1872–'3), and others, and useful encyclopædic manuals by Hagenbach, Pelt, and Staudenmaier.

**THEOPHRASTUS**, a Greek philosopher, born at Eresus, in the island of Lesbos, about 372 B. C., died about 287. His original name was Tyrtamus, and he was surnamed Theophrastus probably for his eloquence. He studied at Athens under Plato and Aristotle, and succeeded the latter at the lyceum. The number of his pupils from all parts of Greece was at one time 2,000. His influence on public affairs excited a party spirit against him, and being brought before the Areopagus on a charge of impiety, he pleaded his own cause, and was acquitted. After this he taught in tranquillity till 305, when Sophocles, son of Amphiclides, carried a law which prohibited all philosophers, under pain of death, from giving any public instruction without the permission of the state. Theophrastus left Athens; but in the next year the law was abolished, and he returned. He wrote works on politics, laws, legislators, and oratory, which are lost, and "A Dissertation on the Senses and the Imagination," a work on "Metaphysics," "Characters," and two works on botany, "The History of Plants" and "The Causes of Plants," which are extant in whole or in part. The book of "Characters" consists of 30 sketches of the general vices of humanity as developed in individuals. His extant works were first printed with those of Aristotle (Venice, 1495–'8); the best edition

is Wimmer's (Leipsic, 1854, and Paris, 1866). His "Characters" were translated into French and prefixed to his own by La Bruyère (1688), and into English, among others, by Francis Howell (London, 1824).

**THEOPHYLACT** (Θεοφυλάκτος), surnamed SIMOCATTA, a Byzantine historian, born of an Egyptian family in Locris in the latter part of the 6th century, died about 629. From 610 till about the close of his life he held various offices at Constantinople. He wrote a history of the reign of the emperor Maurice (582–602), of which a Latin translation, *Historiæ Mauricii Tiberii Imperatoris Libri VIII.*, was published at Ingolstadt in 1648. Besides 85 letters (*Epistolæ Morales, Rusticæ et Amatoriæ*, 4to, Cracow, 1509), he wrote a work on the nature of animals, especially of man ('Απορίαι Φυσικαί, or *Quæstiones Physicæ*, 4to, Leyden, 1596; Leipsic, 1653.) These two works were published together at Paris in 1835.

**THEOPHYLACT**, a Greek theologian, born in Constantinople probably about the middle of the 11th century, died after 1112. He was instructed by Clement, archbishop of Bulgaria, and became archbishop of Achris or Achrida, a chief city of Bulgaria, between the years 1070 and 1077. He engaged in the controversies of his day, especially those relating to the true character, procedure, and office work of the Holy Ghost, and the question whether or not common bread or only unleavened should be used in the sacrament, opposing the views of the Latin church. He compiled commentaries upon the minor prophets and a large part of the New Testament from the works of Chrysostom, and wrote a treatise on royal education (Παιδεία Βασιλική, or *Institutio Regia*) for the instruction of his pupil Prince Constantine Porphyrogenitus, the son of Michael VII. There exist 75 of his letters, with some homilies and orations and a few small treatises. An edition of all his works in Greek and Latin was issued at Venice (4 vols. fol., 1754–'63).

**THERA** (now *Santorin*), an island of the Ægean sea, now forming with Amorgos and other islands an eparchy of Greece, in the nomarchy of the Cyclades; length about 9 m. from N. to S., average breadth about 4 m.; pop. about 13,000; of the eparchy, in 1870, 21,907. It was originally circular, but the islet Therasia was torn from it by an earthquake about 237 B. C., and it now resembles a horseshoe. The harbor thus formed is the crater of a volcano, and as no bottom is found, vessels make fast to the abrupt and rocky shores. The soil is volcanic and inclined to dryness, but very fertile. The annual production of wine is about 1,750,000 gallons. Ship building is the only considerable industry. Thera, the capital, had a population in 1870 of 5,143.—Though an ancient Lacedæmonian colony, Thera is only of historic importance as having sent a colony to found the city of Cyrene in Africa, 631 B. C. The dates of the eruptions known to have taken place in or near this island are 197 B. C. and A. D. 46, 726, 1573, 1707, and 1866. By that of 197 B. C. the island of Palæa (Old) Cammeni was formed, by that of 46 Mikra (Little) Cammeni, and by that of A. D. 1707 Nea (New) Cammeni. The last was at first composed of white pumice, but subsequently received additions of brown trachytic rock. The eruption did not wholly cease or the island assume its present form till 1712. In the beginning of 1866 stones flew up from the port of Volcano, and a new volcano arose which attained a height of about 100 ft. The eruptions continued until the autumn of 1870, and enormous quantities of lava were thrown out, surpassing in size those projected in 1707–'12. Near Nea Cammeni a regular cone was formed 325 ft. high.

**THERAMENES**, a political leader at Athens toward the end of the 5th century B. C., born in Cos. In 411 he became a member of the council of 400; but he deserted it and became one of the leading agents in its overthrow. In 410 he joined the fleet under Thrasybulus, and took part in the battle of Cyzicus; and in 408 he participated in the siege of Chalcedon and the capture of Byzantium, under Alcibiades. He was one of the inferior generals at the battle of Arginusæ in 406; and it was chiefly through his influence that six of the commanders were condemned to death for not saving the drowning crews, although, as they asserted, he had himself been sent with others to perform that office. During the siege of Athens by the Spartan general Lysander, when the city was reduced to great extremity, Theramenes was sent as envoy to the Lacedæmonians. He remained three months with Lysander, who he pretended detained him that length of time without informing him that the ephors only had power to grant peace; and upon his return to the city, which was now suffering under a terrible famine, he was sent back to make peace on any terms. The hard conditions imposed by the Lacedæmonians were assented to (see GREECE, vol. viii., p. 195), and in 404 Theramenes, who during his three months' stay with Lysander had made arrangements with the Athenian oligarchical exiles, was among the most active in subverting the constitution, and became one of the thirty tyrants. He warmly supported the first measures of the government in crushing the democracy and putting to death its prominent leaders; but he afterward opposed the violent measures of Critias and his colleagues. His party daily increased; but Critias, after charging him with being a public enemy, caused him to be dragged off to prison by partisans with concealed daggers whom he had brought into the senate house, and compelled him to drink the hemlock.

**THERESA**, or **Teresa, Saint**, a Spanish mystical writer, born in Ávila, March 28, 1515, died at Alba, Oct. 4, 1582. She was called Teresa de Ahumada (her mother's family name) till Au-

gust, 1562, when she assumed that of Teresa de Jesus. At the age of 20 she entered the order of Carmelites in a convent of her native town, in which she remained 27 years. She then founded a reformed branch of the Carmelites (Barefooted Carmelites), sometimes called after her Theresians. During her life 29 convents of the reformed order were established, and in the 18th century it counted about 2,000 members in six provinces, in Spain and Spanish America. She was beatified by Pope Paul V., April 24, 1614, and canonized by Gregory XV., March 22, 1622, her feast being fixed on Oct. 15. Theresa described the internal struggles and aspirations of her heart and her frequent mystic visions in ascetic treatises and letters, which are among the most memorable documents of the mystic literature of the Roman Catholic church, while their excellence of language and style has secured for them a place in the classic literature of Spain. Five of them are extant: *Discurso ó relacion de su vida*, written in 1562; *El camino de la perfeccion*, prepared in 1563 as a guide for the nuns of her reformed order; *El libro de las fundaciones*, an account of the convents founded by her; *El castillo interior, ó las moradas*, written in 1577, and the most celebrated of her mystic works, in which she portrays in glowing colors the gradual progress of the soul to the seventh heaven, the celestial castle of Christ, her spouse; and *Santos conceptos de amor de Dios*, the original of which she burned in obedience to her confessor, but which has been preserved from a copy taken by one of the nuns. The original manuscripts of the first four works are preserved in the library of the Escurial. The first complete edition appeared at Salamanca in 1587, and a recent one, edited by Ochoa, at Paris in 1847 (*Tesoro de las obras misticas de Santa Teresa de Jesus*). A collection of letters of St. Theresa, addressed to different persons, was published at Saragossa in 1658. The abbé Migne edited a complete collection of her works in French (4 vols., Paris, 1840–'46), and they have been translated into most other European languages. A French translation from the original manuscripts was published by Père Marcel Bouix (3 vols. 8vo, Le Mans, 1852–'6). Among the many lives of St. Theresa are those of Ribera (Salamanca, 1590; French by Père Bouix, Paris, 1865), the Bollandist Vandermoere (Brussels, 1845), and Maria French (London, 1875).

**THERESIOPEL,** or **Maria-Theresiopel.** See SZABADKA.

**THERMAIC GULF.** See SALONICA.

**THERMO-ELECTRICITY,** electricity developed by heat, and also the science which treats of the phenomena and mode of production. Prof. Seebeck of Berlin, in 1822, was the first to make any well directed observations upon the subject. He found that when two rods or bars of different metals were soldered together or otherwise held in intimate contact at their ends, and the junction heated, an electrical disturbance took place, and that if the ununited ends were connected by a conductor an electric current was established. Several crystals, while their temperature is rising or falling, also become oppositely electrically excited at their opposite ends. The term pyro-electricity is usually applied to the electrical phenomena which arise from changes of heat in crystals. These phenomena were first observed in tourmaline, a double-refracting silicate crystallizing in hexagonal prisms. (See TOURMALINE.) Its electrical manifestations are confined within certain limits of temperature, chiefly between 50° and 300° F., but these limits vary with the length of the crystal. If a crystal of tourmaline is suspended by a thread at its middle, and heated, its ends will be attracted and repelled by electrically excited bodies. Many other crystals exhibit like phenomena, but less in degree, which in many cases can only be detected by a delicate electroscope. That pole of a crystal at which the algebraic sign of the change of temperature is the same as that of the electricity developed, that is to say, which manifests positive electricity when the temperature is rising, is called the analogous pole, and the other, the antilogous pole. Brazilian topaz becomes electrical when heated, the Siberian variety slightly, the Saxon not at all. When the first two are treated negative electricity appears at both ends of the crystal, while the positive is developed on the lateral faces. Pyro-electricity is chiefly developed in hemihedral crystals. The phenomena of thermo-electricity in metals is most strongly marked when two metals are heated at their junction; but if a wire of a single metal be tied in a knot, and be heated on one side of the knot, electrical disturbance will take place. When two metals are employed, the strength of the current appears to be in proportion to the difference of temperature of the two metals on each side of the junction, and its direction and also its strength upon the natures of the metals used. In fig. 1, $m\ n$ represents a plate of copper, soldered on to a plate of bismuth, $o\ p$, the middle of which also supports a magnetic needle, beneath the copper plate. If heat be applied at $o$ while the axis of the instrument is in the magnetic meridian, the north pole of the needle will be deflected to the left hand of an observer looking from $n$ to $m$ (see GALVANISM, vol. vii., p. 592), which indicates that a galvanic current is passing through the copper from $n$ to $m$. If however the junction $n\ o$ is cooled, the current will flow from $m$ to $n$. In the following list, according to Becquerel, the direction of the current will be from any element to any one following, the intensity being greatest between the first and the last: bismuth, platinum, lead, tin, gold,

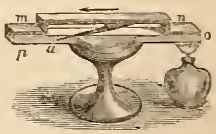


FIG. 1.

silver, copper, zinc, iron, antimony. The direction of the current often changes when the couple is heated beyond a certain degree. Thus, in a copper and iron circuit, the current passes from the copper to the iron through the heated part when the temperature is not higher than 570°; above this the curent passes in the opposite direction. The cause of thermo-electric currents is diversity in the molecular structure of the elements, and Becquerel ascribes them to unequal propagation of heat in the different parts of the circuit. A thermo-electric pile, or battery, in which a series of several couples are joined somewhat like the arrangement in a voltaic pile, or at least with the opposite poles of the elements in contact with each other, was devised by Nobili. A modification of this is shown in fig. 2, in which the lowest plate is bismuth, the next above antimony, the next again bismuth, and so on, the last plate being antimony. These sets of elements are arranged in a copper frame, P, in four vertical series, making in all 20 couples. The terminal plates are connected with binding screws, *m* and *n*, by which they may be connected with a resistance measurer or rheostat, or with a sine or a tangent galvanometer. (See GALVANISM, vol. vii., pp. 593–'5, and DIATHERMANCY, vol. vi., p. 81.) When the pile is composed of a great number of pairs and connected with a very delicate galvanometer, it may be used to detect the slightest changes of temperature; it is much employed in physical investigations, and will undoubtedly in time have extended practical use in physiology and medicine.

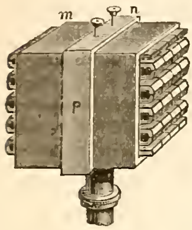

FIG. 2.

**THERMOMETER** (Gr. θέρμη, heat, and μέτρον, a measure), an instrument to measure temperatures. It is formed of two or more different substances, the volumes of which expand and contract to different extents when they are simultaneously exposed to the same differences in intensity of heat. The first attempt at indicating to the eye differences of temperature seems to have been by the contrivance variously ascribed to Drebbel of Holland and Sanctorius of Italy, about the beginning of the 17th century, and known as a weather glass. This was very rude and inaccurate, consisting of a glass bulb and tube inverted, opening below into a cup of colored liquid, which, the air of the bulb having been partly expelled by heat, rose in the tube, and stood at different heights according as the air remaining in the bulb was more or less expanded by heat. This, the origin of the common air thermometer, as improved by Boyle and by the Florentine academicians, became transformed to a smaller bulb with upright stem of somewhat fine bore, the contained liquid being colored spirits of wine; boiling this to expel air, the tube was hermetically sealed, and the whole then affixed to a case. A scale of degrees was also introduced, its fixed points being the cold of snow or ice and the greatest heat known at Florence; it was of necessity very variable in its indications. At this stage in the progress of thermometry, much discussion in regard to the most suitable fixed points for the scale, the best substance for use in the instrument, &c., including that of the question whether water did not freeze at different temperatures in different latitudes, was carried on in England and on the continent. Hooke advocated as the lower fixed point the temperature of freezing water. Newton seems first to have discovered or taken advantage of the facts, that a thermometer placed in melting snow or ice always indicates the same temperature, and always very nearly one temperature in boiling water; but of oil, which he suggested for the liquid in the bulb, the movements were found to be too sluggish and uncertain. Römer, overcoming a prejudice that seems to have existed in regard to unequal expansion of mercury, first adopted that liquid; and he doubtless devised the instrument and scale usually attributed to Fahrenheit of Amsterdam (1720), the latter constructing and introducing the instrument, so that it became generally known throughout Europe in the first half of the 18th century. Of this thermometer, the lower fixed point, or zero, was taken at 32° below freezing point of water; but whether as the cold obtained by its maker by mixing salt and snow, or as the greatest cold observed in Iceland, and in either case as the supposed point of absolute cold, is not now definitely known; and since Fahrenheit kept his graduation of thermometers a secret, the same must be said respecting the choice of a scale of 180° between the fixed points. Celsius of Sweden (1742) introduced a scale of 100° between the fixed points; this was adopted in France at the time of the revolution, and named the *thermomètre centigrade;* and owing to its convenient decimal division, it has been wholly adopted in several countries of Europe, while it is coming into general use among scientific men throughout the world. For the general principles upon which the use of the thermometer depends, see EXPANSION, HEAT, and PYROMETER.—An increase in the temperature of a body is generally accompanied by an increase in its volume, and a decrease in its temperature by a contraction in its volume. Definite changes in the volume of a given substance may be used as indications of this substance having different definite temperatures, and this substance will have the temperature of the bodies by which it is surrounded, or of the medium in which it is immersed, and thus serve to measure their temperature. The substances generally used in the thermometer are glass and mercury, and the observed change of volume is the difference in the change of volume of the glass and of

the mercury. The instrument which shows this difference in expansions is known as the mercurial thermometer. It consists of a tube of very small interior diameter, terminating in a bulb or reservoir. The bulb and a portion of the tube are filled with mercury, and with an increase or a diminution of temperature the mercury will rise or fall in the tube; and the position of the mercury in the tube can be noted on a scale of equal parts either etched on the tube or marked on the surface or a plate to which the tube is attached. Mercury has several advantages as a thermometric substance. The successive increases in its volume for equal and successive additions of temperature, indicated by the air thermometer (see PYROMETER, vol. xiv., p. 111), are quite uniform; especially is this the case when we use the differential expansion of mercury and ordinary glass. The ordinary thermometer when constructed with care is trustworthy in the measure of temperatures up to 300° C. Up to 100° C. mercurial thermometers made of any kind of glass indicate almost exactly the same temperatures as those given by the air thermometer. Another advantage of mercury is that it does not freeze above the low temperature of —40° C., and does not boil below 360° C. But the mercury thermometer only gives accurate indications between —35° and +300° C. For temperatures above 300° C. some form of pyrometer must be used. Mercury has a low specific heat, and this property combined with its high conductivity causes it rapidly to indicate the changes in the temperature of surrounding bodies or of the medium in which it is immersed.—*Construction of the Mercurial Thermometer.* The tube of the thermometer should be of uniform calibre throughout its whole interior. To ascertain whether this is the case, a short column of mercury is introduced into the tube; and if its length remains the same when it is moved throughout the length of the tube, we may be sure that the tube has a uniform bore, and hence that equal amounts of expansion of the mercury will cause equal additions in the length of the mercurial column in the tube. Since tubes of uniform bore are very rare, it is generally necessary to calibrate the tube before its graduation. This is done by etching on the tube a scale of equal parts, and then, from observations on the different lengths occupied by a column of mercury which is made to pass through the tube, forming a table which gives the temperatures corresponding to the arbitrary divisions on the tube. A bulb is now blown on the tube, and this bulb and a portion of the tube are filled with mercury as follows: The air in the bulb is heated while the open end of the tube dips into mercury. The heat having been withdrawn, the air in the bulb contracts and the mercury rises in the tube and partly fills the bulb. To the open end of the tube a funnel containing mercury is adapted, and the mercury in the bulb is boiled and thus expels all air and moisture from the instrument, which on cooling necessarily fills completely with mercury. The bulb is now placed in some fluid heated to a few degrees above the highest temperature which the thermometer is intended to measure, and when the mercury ceases to overflow the open end of the tube is sealed with a blowpipe flame. In order to graduate the instrument, the bulb and part of the tube are surrounded with melting ice, and when the top of the mercury column has remained some time stationary, its position is marked by means of a line, or a note is made of this position, referred to the arbitrary scale etched on the tube. The point on the thermometer determined as above is designated as 0°, or zero degree, on the thermometers known as centigrade (Celsius) and Réaumur, and as 32° on the Fahrenheit system of graduation. To determine a higher point on the thermometer, the instrument is placed in the interior of a metallic vessel with double walls, between which circulates the steam from water boiling in the bottom of the vessel. When the top of the mercury column in the thermometer has become stationary its position is marked on the tube. The boiling point of water is constant at the same atmospheric pressure, and when the barometric column has a height of 29·922 inches or 760 millimetres, the boiling point of water is designated as 100° on the centigrade thermometer, 212° on the Fahrenheit, and 80° on the Réaumur. Hence, between the melting point of ice and the boiling point of water there are 100 equal degrees in the centigrade graduation, 180 in the Fahrenheit, and 80 in the Réaumur. To convert the indications of one of these thermometers into those of the other two, we have the following formula, in which F, C, and R denote equivalent temperatures expressed in degrees of Fahrenheit, centigrade, and Réaumur, respectively:

$$F = \tfrac{9}{5}C + 32 = \tfrac{9}{4}R + 32$$
$$C = \tfrac{5}{4}R = \tfrac{5}{9}(F - 32)$$
$$R = \tfrac{4}{5}C = \tfrac{4}{9}(F - 32)$$

Fig. 1 shows a thermometer graduated according to the three systems. A few weeks after a thermometer has been made and graduated it may be observed that the mercury will not quite descend to the melting point of ice when the instrument is immersed in pounded ice. It has been found that this "elevation of the zero point," as it is called, goes on gradually for about two years after the thermometer has been con-

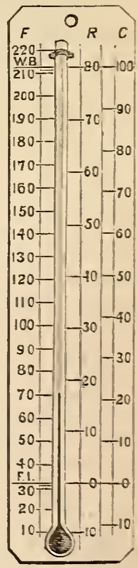

FIG. 1.—Thermometer with Fahrenheit, Réaumur, and Centigrade Scales.

structed, and at the expiration of that period the readings may all be too low by nearly a degree; hence it is necessary either to add the proper correction to the readings of the thermometer, or to slide down and refix the scale to which the thermometer is attached, so that it will read accurately. Alcohol, commonly used where temperatures much below 0° F. are to be observed, is liable at such range to much variation, although it does not freeze even at −132° F.; and Capt. Parry, in his arctic voyages, observed differences of full 10° C. between alcohol thermometers by the best makers.—*Self-recording Thermometers.* Various instruments have been invented which record the indications of the thermometer. They may be divided into two classes, those which record only the maximum and the minimum of the temperatures occurring in any definite period, and those which produce continuous records. In the first class may be mentioned the two following instruments. An ordinary mercurial thermometer has its tube constricted to a thin passage at some point between its bulb and the beginning of its scale. This thermometer is placed in a horizontal position, and then as long as an increase of temperature takes place small portions of

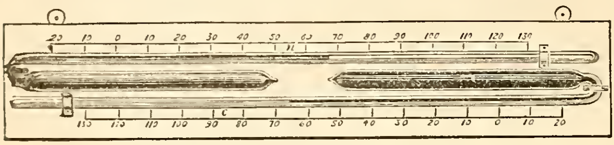

Fig. 2.—Maximum and Minimum Thermometers.

the mercury will go in a series of jumps across the constricted passage; but on a fall of temperature the mercury contracts into the portion of the thermometer below the constriction, leaving a column of mercury above it. The upper end of the latter column marks the highest temperature reached during the time of exposure. To readjust this instrument, the mercury is sent into the vacant space below the constriction by swinging the instrument. Fig. 2 shows this "maximum thermometer," the invention of which has been claimed by several persons. The "minimum thermometer" of Rutherford, which is generally used, is made of alcohol contained in the ordinary glass bulb and tube. In the column of alcohol is a small index made of black glass and shown at $n$, fig. 3. This piece of glass is brought up to the end of the fluid column by inclining the instrument. The thermometer is then placed in a horizontal position, and as the temperature falls the top of the liquid column during its retraction carries the glass index with it, and leaves it at the point which indicates the minimum temperature reached during the exposure of the instrument. The thermometers of

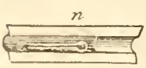

Fig. 3.—Index of Rutherford's Thermometer.

the second class give continuous records, either by causing a tracer attached to some simple or compound metallic bar to mark a continuous line on a cylinder which revolves once in 24 hours, or by the aid of photography a continuous impression of the image of the top of a thermometric column is obtained by illuminating a thermometer placed in front of the lens of a camera, while at the back of the camera is a sensitized plate on which the image is formed. The plate traverses athwart the beam issuing from the lens by a known distance each hour.—*Differential Thermometer.* This is a modification of the air thermometer, in which two large glass bulbs above are connected by a glass tube bent twice at right angles; the horizontal and parts of the upright tubes are filled in the common form with a colored liquid, which is depressed on either side as the corresponding bulb is more heated; thus the instrument indicates differences of the temperatures to which the two bulbs may be exposed. It is very sensitive; and by a scale the results it affords are comparable with each other.

**THERMOPYLÆ**, or simply **Pylæ** (from θερμός, hot, and πύλη, gate), a defile between Thessaly and Locris, in antiquity the only passage for an enemy from northern into central Greece, situated between Mt. Œta and an inaccessible morass forming the edge of the Maliac gulf, and containing several hot springs. There was a road wide enough only for a single wheel track, which formed the western gate. About a mile to the eastward Mt. Œta again approached the sea in a similar manner, and the passage there formed the eastern gate. The space between these two gates was wider, and many years before Leonidas occupied the pass, the Phocians had so conducted the warm springs over the ground as to render the pass impracticable. They had also built a wall near the western gate to prevent the incursions of the Thessalians, which was in ruins when the Spartans came. This pass is celebrated for its defence against the army of Xerxes by the Greeks under the Spartan king Leonidas, in 480 B. C. His forces numbered probably about 7,000; but when during the battle he learned that one Ephialtes, a Thessalian, had betrayed to the Persians a circuitous path over the mountains leading to their rear, he dismissed all but his chosen band of 300 Spartans, with a number of helots, about 700 Thespians who volunteered to share his fate, and apparently 400 Thebans. This small host sallied out and fought till Leonidas and all the Spartans and Thespians were killed. The fate of the Thebans is uncertain; according to some they surrendered to the Persians. One Spartan, Aristodemus, who was prevented by illness from partaking in the combat, returned home, and was received with scorn, but in the following year retrieved his honor by a heroic death at

Platæa. Many other battles took place at Thermopylæ in later times.—The pass is now of little importance as a strategic point. Nature has widened it into a swampy plain from the alluvial deposit of the Sperchens and the retreat of the Maliac gulf. At the S. end of the pass is a mound, supposed to be that to which the Spartans finally retreated and on which they were slain. In a small plain is the Polyandrium, one of the sepulchral monuments of the Greeks who fell at Thermopylæ, and a few miles beyond are the remains of the wall mentioned above, which can be traced from the Maliac gulf to the gulf of Corinth.

**THÉROIGNE DE MÉRICOURT** (more properly MARCOURT), a French revolutionist, whose real name was Anne Josèphe Terwagne, born at Marcourt, Luxemburg, Aug. 13, 1762, died in Paris, June 9, 1817. She was the daughter of a farmer, and was educated at a convent. In 1789 she went to Paris, where she became notorious as the "Amazon of the revolution" and the "handsome Liégeoise." She lived in luxury, gathered around her many conspicuous revolutionists, and appeared with arms in the revolutionary assemblies, in which she spoke with eloquence. In 1790 she was threatened with arrest for participating in violent outbreaks, and fled. Early in 1791 the Austrian authorities arrested her near Liége, and incarcerated her at Kufstein, Tyrol, for alleged conspiracy against Marie Antoinette, and subsequently detained her at Vienna till November. On her return to Paris she became still more popular. In June, 1792, she led a corps of insurgents, and received a civic crown for her courage. Suleau, a journalist, having reviled her, she turned the mob upon him during the outbreak of Aug. 10, 1792, and he was murdered. But when a little later she advocated greater moderation, she was publicly stripped and whipped by infuriated women. This drove her mad, and for the rest of her life she was in a lunatic asylum.—See *Théroigne de Méricourt, dite la belle Liégeoise*, by Fuss (Liége, 1854).

**THESEUS**, a legendary hero of Attica. He was the son of Ægeus, king of Athens, and Æthra, daughter of Pittheus, king of Trœzen. Ægeus on his departure from Trœzen hid his sword and shoes under a stone, and charged Æthra if she gave birth to a son to send him to Athens as soon as he was able to roll away the stone. When Theseus arrived at maturity his mother informed him of his parentage, and taking possession of the tokens he set out for Attica by land, destroying various robbers and monsters on the way. At Athens he was recognized by his father, but narrowly escaped death from the hands of Medea. He engaged in a war with the Pallantids, the sons and grandsons of Pallas, the brother of Ægeus, in regard to the succession to the throne, and was victorious. Next he voluntarily sailed to Crete as one of the tribute youths to be offered to the Minotaur, for the purpose of attempting the destruction of the monster. He gained the affections of Ariadne, daughter of Minos, who furnished him with a sword and a clue of thread, with which he killed the Minotaur and escaped from the labyrinth. Hereupon he carried off Ariadne, whom however he left behind at the island of Naxos. Theseus, if successful, was on his return to hoist white sails instead of the black ones which this vessel always carried; but this arrangement was forgotten, and Ægeus, imagining his son was destroyed, threw himself into the sea. Theseus now ascended the throne. He invaded the territory of the Amazons, defeated them, and carried off their queen Antiope. In revenge the Amazons marched into Attica, and entered Athens itself, but were finally vanquished. He married Phædra, and to her passion his son Hippolytus fell a victim. (See PHÆDRA.) Theseus figures in the principal heroic legends of ancient Greece. He was one of the Argonauts, was engaged in the Calydonian hunt, fought with Pirithous and the Lapithæ against the Centaurs, and also assisted Adrastus in regaining the bodies of those slain before Thebes. Aided by Pirithous, he carried off Helen from Sparta when she was only nine years old. Attica was in consequence invaded by Castor and Pollux. Menestheus incited the Athenians to rise against their ruler; and Theseus, finding it impossible to sustain himself, retired to the island of Scyros, where he was destroyed by the treachery of King Lycomedes. In 476 B. C. the oracle directed his bones to be brought from the island to Athens, and in 469, when Scyros was taken by Cimon, it was pretended the body was found. His bones were laid in the interior of the city, and the temple called the Theseum, built over the spot, served as a sanctuary for poor men in dread of the powerful, and for slaves in case of cruel treatment. At the battle of Marathon Theseus was reported to have been seen armed and aiding the Athenians. Festivals in his honor were celebrated on the eighth day of each month, and the festival termed Oschophoria was said to have been originated by him after his return from Crete. To him was popularly ascribed the reinstitution of the Pythian games.

**THESIGER**, Sir Frederick. See CHELMSFORD.

**THESPIS**, the founder of Greek tragedy, a native of Icaria in Attica, lived in the time of Pisistratus (about 540 B. C.). The ancient traditions represent him as the inventor of tragedy, and to him is also ascribed by some the invention of masks. According to one account, Thespis was in the habit of travelling through Attica at the time of the festival of Bacchus in a wagon, and upon this portable stage performed comic plays. It is also said that he found tragedy already existing in Athens, but made in it the simple and important alteration of introducing an actor for the sake of giving rest to the chorus. Nothing which he wrote is extant, but the titles of four of his tragedies have been preserved.

**THESSALONIANS, Epistles to the**, two canonical books of the New Testament, addressed to the church at Thessalonica by the apostle Paul. They are expressly referred to by Irenæus, Clement of Alexandria, and Tertullian. In modern times the authenticity of both epistles has been doubted by Noack, Van der Vries, and Volkmar, and that of the second by Lipsius, Hilgenfeld, Weisse, Hausrath, Pfleiderer, and others. Special treatises in support of their authenticity have been written by W. Grimm, Lünemann, and others. The first epistle to the Thessalonians, commonly believed to have been the first of the Pauline epistles, is supposed to have been written from Corinth about A. D. 52 or 53. The occasion seems to have been the favorable report of the faith of the Thessalonians which Timothy brought on his return from Macedonia. Chapters i. to iii. express the apostle's feelings respecting their religious condition, and his own kindly reception among them. Then follow an exhortation to holiness (iv. 1–12), an instruction on the fate of the dead at the expected return of Christ (iv. 13–18), an admonition to be always prepared for that event (v. 1–11), several other admonitions, and the conclusion. The second epistle is believed by most of the theologians who regard it as authentic to have been written soon after the first, in the year 53 or 54. It was designed to correct some errors into which the church had fallen, especially respecting the coming of Christ. The apostle commends the Thessalonians for their patience and faith in their persecutions, and announces that those who trouble them will be punished (ch. i.); he shows that the arrival of Christ was not near at hand, but must be preceded by a great apostasy and the appearance of the Antichrist (ii. 1–12), and gives them appropriate admonitions (ii. 13–17, and iii.). Among the most valuable commentaries on these epistles are those by Schott (Leipsic, 1834), Jowett (London, 1856), Lünemann (Göttingen, 1859), Ellicott (2d ed., 1862), Hofmann (1862), and Auberlen and Riggenbach in Lange's *Bibelwerk* (2d ed., 1867; English translation by Lillie).

**THESSALONICA.** See Salonica.

**THESSALY** (Gr. *Θεσσαλία* or *Θετταλία*), the largest political division of ancient Greece, comprising in its fullest extent the country between Thermopylæ and the Cambunian mountains in one direction, and between the range of Pindus and the Ægean sea in the other. But Thessaly proper was the plain between the Cambunian mountains on the north, Ossa and Pelion on the east, Mt. Othrys on the south, and the Pindus range on the west. This plain, whose natural enclosure of mountains is broken only at the northeast by the vale of Tempe, was the most fertile region and the largest that was continuously productive in Greece, and was supposed by its inhabitants to have once been a lake, of which the lakes Nessonis (now Kara Tchaïr) and Bœbeis (Karla) were the remains. It was drained by the Peneus (Selembria or Salamvria) and its tributaries, and was divided into two plains, which in antiquity were called Upper Thessaly and Lower Thessaly; the former embracing Thessaliotis and Hestiæotis, between Æginium in the northwest and Thaumaci in the south, and having Pharsalus for its chief city; the latter, Pelasgiotis, stretching from Mts. Olympus and Ossa on the north to Mt. Othrys and the gulf of Pagasæ (now of Volo) on the south, and having Larissa as its most important town. Thessaly proper was early divided into the four districts of Thessaliotis, Hestiæotis, Pelasgiotis, and Phthiotis; and this division, the origin of which is sometimes ascribed to Aleuas, the founder of the Aleuadæ, was continued down to a very late time. In addition to Thessaly proper, the name was extended over Malis or Malia, a narrow valley between Mts. Othrys and Œta, through which the river Spercheus enters the Maliac gulf; and to Magnesia, a region lying along the coast and stretching S. from the vale of Tempe, and almost encircling the gulf of Pagasæ.—The Thessalians were said to have been originally emigrants from Thesprotia in Epirus, who conquered the Pelasgian inhabitants of the plain of the Peneus, which is said by Herodotus to have then been called Æolis. During the historic period three classes inhabited the country. The first was a body of rich oligarchical proprietors, who owned most of the soil. Of these the most powerful families were the Aleuadæ of Larissa, the Scopadæ of Crannon, and the Creonidæ of Pharsalus; the second were the subject Achæans, Magnetes, and Perrhæbi, who retained their tribe names and separate votes in the Amphictyonic council; the third were the Penestæ or serf cultivators of the soil, who could not be sold out of the country, and who kept up among themselves the relations of family and community. These were no doubt earlier inhabitants reduced to serfdom; but whether they were Pelasgians or Bœotians, as Grote suggests, it is impossible to determine. The language spoken in Thessaly was Æolic Greek. The four divisions of the country formed a political union, existing rather in theory than in fact. To enforce obedience to the common authority a chief or *tagus* was sometimes elected; but constant feuds between the larger cities prevented Thessaly from occupying its rightful position in Greece. The inhabitants were early engaged in a constant war with the Phocians; they joined by constraint the army of Xerxes in his invasion of Greece, but took no part in the Peloponnesian war. About 400 B. C. Pheræ rose to political supremacy in Thessaly under Lycophron, who had made himself tyrant, and his successor Jason, who reduced all Thessaly to his authority, and meditated not only the conquest of Greece, but the overthrow of the Persian empire; but before he had time to mature his designs he was assas-

sinated. Alexander of Pheræ maintained and extended his power (see PHERÆ); but after his death the country fell into the hands of Philip of Macedon. It formed a part of the Macedonian monarchy until the defeat of Philip V. at Cynoscephalæ in 197, when it came under the Roman dominion, and the government was given to wealthy persons, who met in Larissa.—Thessaly now forms a part of the Turkish vilayet of Janina, excepting the southernmost portion, from Mt. Othrys, which belongs to Greece. (See PHTHIOTIS.) The chief town of Turkish Thessaly is Trikala, and of the Greek portion Lamia or Zeitun.

**THETIS**, in Greek mythology, the mistress and chorus leader of the 50 Nereids, the wife of Peleus and mother of Achilles. She dwelt in the depths of the sea with her father Nereus, and was sought in marriage by both Jupiter and Neptune; but the gods relinquished their suit when Themis declared that the son of Thetis should be more illustrious than his father. At her wedding with Peleus all the gods and goddesses were invited, excepting Eris, who revenged herself by throwing the apple of discord among the guests. (See PARIS, and ACHILLES.) She had a temple in Thessaly, and was worshipped in Sparta and Messenia.

**THÉVENOT. I. Melchisedech**, a French traveller, born in Paris about 1620, died at Issy, Oct. 29, 1692. He early explored Europe, learned oriental languages, and in 1684 became keeper of the royal library, of which he published a catalogue in 1694. The gatherings of learned men at his house formed the nucleus of the future academy of sciences. In 1645 he was sent on an official mission to Genoa, and from 1652 to 1655 he was employed by the government in Rome. He published compilations of travels, including *Relations de divers voyages curieux* (2 vols. fol., Paris, 1663–'72), and *Recueil de voyages*, comprising Marquette's *Découvertes dans l'Amérique Septentrionale* (1681). **II. Jean de**, a French traveller, nephew of the preceding, born in Paris, June 6, 1633, died at Miana, Armenia, Nov. 28, 1667. After travelling through Europe, he made two extensive journeys in Asia and Africa, and is said to have first introduced coffee into France. The narratives of his travels were collected under the title *Voyages de M. Thévenot tant en Europe qu'en Asie et en Afrique* (5 vols. 12mo, Paris, 1689), and were translated into English, German, and Dutch.

**THEZA**, or **Tesa**, a fortified town of Morocco, on the Wad el-Asfar (Yellow river), or Sebu, about 60 m. E. of Fez; lat. 34° 9′ N., lon. 3° 55′ W.; pop. about 5,000, of whom 800 are Jews. Its great mosque is a fine building, supported in the interior by antique monolithic columns. Theza is the centre of the trade between Algiers, Tlemcen, and Fez, and caravan roads lead from it to Fighig and Tafilet.

**THIBAUT** (THEOBALD) **IV. or VI.** as count of Champagne, I. as king of Navarre, a French *trouvère* or poet, born at Troyes in 1201, died there or at Pamplona, July 10, 1253. He was a posthumous son of Count Thibaut III. or V., was educated at the court of Philip Augustus under the supervision of his mother, Blanche, daughter of Sancho the Wise, king of Navarre, and became an early adept of the "gay science." Several of his poems were addressed, under an assumed name, to Blanche of Castile, the queen of Louis VIII., whom he loved to distraction, although she was 14 years his senior. When her husband died prematurely at Montpensier in 1226, while returning from an expedition against the Albigenses, Thibaut, who accompanied him, was suspected of being his poisoner. He soon after joined the league of feudal lords who rose against Blanche, then regent; but her influence brought him back to his duty to the king, and through his assistance she baffled the designs of the confederates. In 1234 Sancho died without male issue, and the count of Champagne inherited the kingdom of Navarre in right of his mother. In 1239 he went to the Holy Land; but he met with a dreadful defeat near Gaza, and had to pay a heavy ransom for the release of his brother. His provinces were very prosperous under his government, and he was a patron of literature and the fine arts. He allowed the Albigenses to be persecuted in his dominions, and assisted, May 13, 1239, in the burning at the stake of 83 of them, at Montrimer, near Vertus. Of his poems, 66 songs were published by Lévesque de la Ravallière (2 vols. 12mo, Paris, 1742; best ed. by Rocquefort and Michel, 1829). A collection of 81 songs is contained in Tarbé's *Collection des poëtes champenois* (8vo, Rheims, 1851).

**THIBAUT, Anton Friedrich Justus**, a German jurist, born in Hameln, Hanover, Jan. 4, 1774, died in Heidelberg, March 28, 1840. He graduated at Kiel, taught jurisprudence there from 1799 to 1802, and at Jena till 1805, and was afterward professor at Heidelberg till his death. In 1814 he advocated a national code, but Savigny regarded it as premature. His principal work is *System des Pandektenrechts* (2 vols., Jena, 1803; 9th ed., 1846; abridged English translation, "Introduction to the Study of Jurisprudence," with notes by Nathaniel Lindley, London, 1855). Guyet has edited his posthumous writings (2 vols., Berlin, 1841–'2).

**THIBET**, or **Tibet** (Sansk. *Bhot;* Thib. *Bod;* Pers. *Tibet*), a region of central Asia, between lat. 27° and 38° N., and lon. 78° and 104° E., bounded N. by East Turkistan and China proper, E. and S. E. by China, S. by Burmah, Bootan, Sikkim, Nepaul, and British India, and W. by Cashmere; area estimated at from 650,000 to 800,000 sq. m.; pop. about 6,000,000. Thibet forms the S. E. portion of the great central Asiatic plateau, with a mean elevation of about 15,000 ft. toward its southern edge, which is bordered by the Himalaya. The Kuen-lun range is generally regarded as the northern boundary of the country. The transverse

chains which connect the western extremities of these two great ranges separate Thibet from Cashmere. It appears now to be established beyond doubt that a third lofty and snow-capped chain intervenes between the Himalaya and the Kuen-lun, parallel with them, probably a prolongation eastward of the Karakorum mountains, under the name of Niantsin-tangla according to Ritter, and Tanla according to Huc. Hodgson calls it the Nyenchhen-thangla range. It forms the northern boundary of Great Thibet, a region which extends thence southward about 200 m. to the outer Himalaya overlooking India, and 750 m. from W. to E. along the basin of the Sanpo or upper course of the Brahmapootra. Western Thibet (Thib. *Ari*), in the widest sense, comprises Ladakh (outside of the limits above stated; see Ladakh) and the lofty Himalaya region about the sources of the Ganges and the Sutlej; while of eastern Thibet (Thib. *Kam*) little is known except that it is deeply indented by the gorge-like valleys of the numerous great rivers which flow thence into China, Indo-China, and Burmah.—In its main physical features Thibet is a vast, arid, mountainous plateau, with an altitude seldom less than 10,000 ft. above the sea, except in the lowest valleys, and over a great part of its area more than 14,000 ft. The northern portion of the country, between the Nyenchhen-thangla range and the Kuen-lun, consists of a series of lofty table lands, uncultivated, and inhabited only by nomads and robbers and the residents of the Buddhist monasteries, which are the only permanent dwellings met with in the region. Great Thibet is comparatively a cultivated country, of settled habitations, and contains the capital and principal cities; but by far the largest part of its surface is occupied by vast grassy steppes, which afford abundant and valuable pasture. In western Thibet the area capable of cultivation, or even habitable by man, is proportionately very small, owing to the exceedingly mountainous character of the region.—Thibet has four systems of drainage. North of the great middle range of mountains, on the slopes of which are numerous glaciers, the drainage is wholly interior, the streams being received by the salt lakes which occupy some of the principal depressions. The most considerable of these is that known as Tengri-nor, or more properly Nam-cho, the Sky lake, 15,190 ft. above the ocean, about 50 m. long and from 16 to 35 m. wide. One of the transverse ridges extending northward from the Himalaya separates the southern part of the country into two basins, forming a watershed with the Indus and the Sutlej flowing off its W. slope, while its E. side sends the Brahmapootra to water Great Thibet, which finally likewise makes its way down to the Indian plain. Near the great Kailas peak of the Himalaya are Lakes Rhawan-rhad and Manasarowar, out of which last pours the Sutlej; and the remarkable ring-shaped lake of Palte, or Yamdok-cho, is about 35 m. S. W. of Lassa, in the valley of the Sanpo or Brahmapootra. Lake Koko-nor, in eastern Thibet, is near the head waters of the Hoang-ho.—The nature of the rocks near the southern edge of the table land indicates that the Thibetan plateau must be of recent geological origin. The plains consist of horizontal gravel strata on which rest bowlders, and extensive fossil-bearing deposits occur in the vicinity of the Himalayan range. In the north metamorphic rocks alternate with beds of granite. Among the Nyenchhen-thangla mountains are numerous hot springs, as well as geysers the waters of which freeze as they fall, forming lofty columns of ice.—The climate in the higher districts is cold, dry, and almost rainless, and even the snowfall is light. Timber never rots, but becomes so dry as to break, and the flesh of animals exposed to the air dries till it can readily be reduced to powder. The limit of perpetual snow is higher on the Thibetan than on the Indian side of the Himalaya, which is attributed to the excessive dryness of the atmosphere on the N. slope of the range. It is there 18,000 or 19,000 ft. above the sea, while in India it descends to 15,000 ft. During summer the sky is clear and the atmosphere wonderfully transparent, but the plains are subject to violent winds and dust storms in winter, and the cold is intense. A warmer climate prevails in many of the valleys, where European fruits and vegetables are raised.—With the exception of the pasturage on the steppes, the vegetation of Thibet is scanty. Forest trees are unknown except in some of the mountainous districts, and in such as have been explored they consist principally of cedar and birch. In the warmer valleys the apple, fig, pomegranate, apricot, peach, vine, and several varieties of nuts are grown. Wheat and rice are cultivated sparingly, and some buckwheat, but gray or black barley is the principal grain and the chief article of diet. The mineral productions comprise gold, silver, mercury, cinnabar, lead, iron, salt, and borax, as well as several kinds of precious stones, including lapis lazuli. Gold occurs, not only in the sands of some of the rivers but in many mines, of which perhaps the most productive are in western Thibet N. of the Kailas mountain. There are rich silver mines in the neighborhood of Lassa, and although it is said that the authorities prohibit working them, large quantities of silver are constantly exported from Thibet into China. Salt, which is also an abundant article of export, is obtained by solar evaporation from the saline lakes. The number of animals is greater than might be expected from the scantiness of vegetation; among them are the tiger, ounce, lynx, wolf, fox, bear, buffalo, wild ox, wild goat, long-haired sheep, and yak, which abounds throughout Thibet. The shawl goat is the most important of the domestic animals, and the musk deer the most valuable object of the chase.

Wild fowl and fish are abundant, but Lamaism prohibits them as articles of food.—The Thibetans belong to the Mongolian race, and it is believed that all were once nomadic, as those in the north still remain. They are pliant and agile, usually brave, generous, frank, and honest, eminently commercial in their habits, and many of them skilled workers in gold, silver, and precious stones. They are rude agriculturists. The fine wool which their flocks afford, and the hair of the shawl goat, enable them to manufacture superior woollens and shawls of fine texture. Sacking and other articles are also woven in considerable quantities for the Chinese market. Cloths are dyed with great skill, and the manufacture of pottery and of idols is a thriving trade. The traffic with China is carried on along the great road between Lassa and Tasienloo, a town in the western part of the Chinese province of Sechuen. The exports are drugs, blankets and other woollens, furs, musk, salt, and silver, in return for which China sends cotton goods and thread, ponies from Yunnan, porcelain, and tea. The chief trade routes from India lead through Cashmere and Ladakh, Nepaul, and Bootan, over lofty mountain passes. English woollen cloths, flowered calicoes, indigo, rice, and precious stones, including pearls, turquoises, and dark corals (which here sell for their weight in gold), reach the country by these highways; while gold and silver, salt, borax, wool of the shawl goat, coarse blankets, ponies, and yaks' tails are sent southward into India over the same routes. The roads throughout the country are poor.—The language which is common to Thibet and Bootan, and hence called indifferently Thibetan or Bhotanta, is classed with the monosyllabic languages, though possessing some polysyllables. Its alphabet is phonetic, reads from left to right, and is evidently borrowed from the Sanskrit; but the language owes most of its derivatives and some of its root words to the Chinese. It is copious and well adapted for the expression of philosophical and religious ideas. There is an extensive literature, mainly composed of translations and commentaries on the Buddhist sacred books. The religion of Thibet is Lamaism. (See LAMAISM.) There are some Mohammedans in western Thibet, chiefly natives of Cashmere, and, according to Huc, several thousand Roman Catholics. Polyandry prevails in many districts.—Politically Thibet is tributary to the emperor of China, and is therefore usually classified as a part of the Chinese empire. But the direct government of the country is vested in the two great lamas or priestly rulers, who hold sway respectively in the two provinces into which Great Thibet is divided for spiritual and administrative purposes. These are the province of U, of which Lassa is the capital, ruled over by the dalai lama, and the province of Tsang, to the southwest, over which presides the equally sacred teshu lama, with his capital at the city of Shigatze, about 140 m. further up the Sanpo valley. The combined names of these two provinces form the native appellation Utsang, applied to Great Thibet. As Lassa is the sacred capital of all Buddhistic countries, it is regarded as the capital of Thibet in preference to Shigatze. There are many other large towns, in most of which the Chinese government has its governors or representatives, who exert great influence if not positive authority over the Thibetan rulers. A considerable Chinese military force has usually been maintained in the country.—As a kingdom Thibet is said to date from A. D. 313. Buddhism was first introduced, according to some authorities, as early as the 4th or 5th century; but its general diffusion there is of later date. After various struggles with China, Thibet finally became tributary to that empire about the middle of the 17th century. The country was visited by Jesuit missionaries in the 17th and 18th centuries. Thomas Manning, an English traveller, made his way to Lassa in 1812, and the abbé Huc in 1845–'6. Although western Thibet has been frequently and quite thoroughly explored, Great Thibet and the eastern and northern parts of the country are very imperfectly known. Much valuable geographical information has recently been acquired, however, through the efforts of the trigonometrical survey of British India, by which native Asiatics trained for the purpose have been despatched to explore the regions N. of the Himalaya. In 1865 and 1871 Great Thibet was visited by three of these trans-Himalayan explorers, and many of the results of their observations are incorporated in this article.

**THIERRY. I. Jacques Nicolas Augustin**, a French historian, born in Blois, May 10, 1795, died in Paris, May 22, 1856. He was educated at the college of Blois and the normal school in Paris, where he began his career in 1814 as a disciple and literary collaborator of Saint-Simon, whom he left in 1817 to elaborate his new historical theories according to the principles of nationalities. He wrote much for the *Censeur européen* (1817–'20), and established his reputation as the most original historian of his day by his *Histoire de la conquête de l'Angleterre par les Normands* (3 vols., 1825; 10th ed., 2 vols. 8vo, 1858, and 4 vols. 12mo, 1860), English translations of which were published in 1825 and 1847, the latter by Hazlitt. These labors impaired his sight, which he lost altogether in 1826, but he continued them with the assistance of secretaries, of whom Armand Carrel was one of the first. After the accession of Louis Philippe, he spent several years with his brother Amédée at Vesoul. At Luxeuil, where he resided in summer, he married in 1831 Julie de Querangal, daughter of a rear admiral, who became of great assistance to him as an amanuensis, and who published several works of her own. She died in 1844, and after residing for some time with the princess Belgiojoso, he spent the rest of his life with his brother's family. Guigniaut characterized

him, in an essay read in 1862 before the academy of inscriptions, as a martyr, and as the first historical scholar who had vindicated the rights of oppressed nationalities. His works include *Lettres sur l'histoire de France* (1827; latest revised ed., 1859); *Dix ans d'études historiques* (1834; 9th revised ed., 1857; English translation, "Historical Essays," 1845); *Récits des temps mérovingiens* (1840; 8th ed., 1864; English translation, 1846); *Recueil de monuments de l'histoire du tiers état*, prepared under the direction of the government and with the assistance of several writers (vols. i. to iii., 1850-'56); and *Essai sur l'histoire de la formation et des progrès du tiers état* (1853; English translation by Francis B. Wells, 2 vols. 12mo, London, 1855). He prepared a complete edition of his works (8 vols. 18mo, 1846-'7; new ed., 10 vols., 1856-'60). **II. Amédée Simon Dominique**, a French historian, brother of the preceding, born in Blois, Aug. 2, 1797, died in Paris, March 26, 1873. He was educated at the college of Blois, and in 1820 received an office in the ministry of marine. In 1828 he was for a short time professor of history at Besançon. At Guizot's recommendation he was appointed in 1830 prefect of the department of Haute-Saône. At the end of 1838 he entered the council of state, of which he was also a member during the second empire, and in 1860 was made a senator. He was less brilliant but more judicious than his brother. His works include *Histoire des Gaulois jusqu'à la domination romaine* (3 vols., 1828; 6th ed., 1866); *Histoire de la Gaule sous l'administration romaine* (3 vols., 1840-'47); *Histoire d'Attila et de ses successeurs* (2 vols., 1856; 3d ed., 1864); *Récits et nouveaux récits de l'histoire romaine* (1860-'64); *Tableau de l'empire romain* (1862); *Saint Jérôme: la société chrétienne à Rome et l'émigration romaine en Terre Sainte* (2 vols., 1867); and *Saint Jean Chrysostome et l'impératrice Eudoxie: la société chrétienne en Orient* (1872).—His son, Gilbert Augustin, published in 1875 a historical drama entitled *Aventures d'une âme en peine*.

**THIERS**, a town of Auvergne, France, in the department of Puy-de-Dôme, on the Durolle, 23 m. E. N. E. of Clermont; pop. in 1872, 16,635. It has two interesting churches, and is chiefly noted for extensive manufactories of cutlery. Paper, playing cards, candles, ribbons, and thread are also manufactured.

**THIERS, Louis Adolphe**, a French statesman, born in Marseilles, April 16, 1797, died in Paris, Sept. 3, 1877. He was educated at Marseilles and studied law at Aix, where he practised from 1818 to 1821. He then followed Mignet to Paris, where he wrote for the *Constitutionnel* and other journals. He became a favorite of Laffitte and Talleyrand, and wrote *Histoire de la révolution française* (10 vols., 1823-'7; English translation with notes by F. Shoberl, 5 vols., London, 1838). In January, 1830, he, Mignet, and Carrel started the *National*, which promoted the change of dynasty effected by the revolution of the following July. Under Louis Philippe he became an official in the treasury and a member of the chamber of deputies. The ministry of finance was tendered to him, but he recommended Laffitte as its chief, though he virtually acted in that capacity, and retired with him, March 13, 1831. On joining Soult's cabinet, Oct. 11, 1832, as minister of the interior, he procured with Deutz the arrest (Nov. 6) of the duchess de Berry (see Berry), and immediately left the department. This act he had deemed necessary for the pacification of the Vendée at the time when all the military resources were needed for the relief of Antwerp in the interest of Belgian independence. Resuming office in December as minister of commerce and agriculture, he obtained large appropriations for public works. Early in 1834 he returned to the interior department, and quelled the bloody insurrections at Lyons and Paris. After ministerial combinations which revealed his disagreement with Soult and Molé and his rivalry with Guizot, he finally retained his office under the duke de Broglie, and at the same time (December) took his seat in the French academy. The attempt of Fieschi upon the king's life (July 28, 1835), from which he himself barely escaped, made him support the restrictive press and jury laws, known as the laws of September. He resigned with the other ministers in January, 1836, on the rejection of the bill for the conversion of the *rentes*, but in February became premier and minister of foreign affairs. On Aug. 25 he retired, chiefly on account of the king's opposition to armed intervention in Spain. His successor Molé in vain tempted him in 1838 with the Russian mission, to get rid of his influence. He was reinstated as premier March 1, 1840, and proposed the fortification of Paris and extraordinary armaments to prepare for war, in view of the complications arising from Mehemet Ali's conflict with the sultan; but being again baffled by the king's "peace at any price" policy, he resigned, and was succeeded by Guizot, Oct. 29. He now began his *Histoire du consulat et de l'empire* (20 vols., 1845-'62; English translation by D. F. Campbell, London, 1845-'62), for which he visited England and examined the battle fields in Germany, Italy, and Spain. At the same time, as the recognized leader of the opposition, he advocated enlightened measures of education and progress, and opposed ultramontane schemes and political corruption. He also denounced the right of search, and the excessive complacency toward England in the Pritchard question (see Du Petit-Thouars), and in adopting her objections against the incorporation of Texas with the United States, on which occasion he deprecated alienation from the "great American nation, the harbinger of French liberty." Shortly before the outbreak of the revolution of 1848 he made withering attacks upon Louis Philippe's pusillanimity in foreign affairs, and favored politi-

cal reforms, but not a republic. Yet when this became an accomplished fact (Feb. 24), he accepted it as a protection against monarchical factions, and in June was elected to the constituent assembly. When Cavaignac asked for extraordinary powers against the socialists, he was the first to concede them; but subsequently he supported Louis Napoleon for the presidency, and fought a duel with Bixio for repeating a rumor, which he denied, that he had previously disparaged such an election. Elected to the legislative assembly, he was one of the most active leaders of the reactionary majority. In January, 1851, however, after the removal of Changarnier, he raised his warning voice against a new Napoleonic empire. In November he adjured the assembly to adopt Baze's resolution for its military protection, and in vain admonished the radicals that the rejection of this measure threatened the safety of the most truly representative body which France ever had. He was arrested on the *coup d'état* of Dec. 2, imprisoned till Jan. 9, and banished till Aug. 7, 1852. He kept aloof from politics until the apparent relaxation of the autocratic régime encouraged him in 1863 to solicit the suffrages of Paris liberals, who returned him (May 31), despite governmental opposition. In 1865 he referred in his great speech on the budget to the extravagant expenditures for the Italian war, the Mexican expedition, and Haussmann's stupendous enterprises. In 1866 and 1867 he exposed the fatal blunders of the emperor in permitting the aggrandizement of Prussia and the unification of Italy, to the detriment of the grandeur of France. In 1870 he opposed the declaration of war against Prussia, maintaining that the government, being unprepared, was rushing to a certain defeat; and his influence rose with the verification of his predictions. He urged the vigorous defence of Paris, and visited the principal foreign courts to secure their influence in favor of an armistice. On his return in October, he had several interviews with Bismarck, but without results excepting that his efforts increased his popularity and the universal confidence in his statesmanship. On Feb. 8, 1871, he was elected to the assembly in 26 departments, and selected that of Seine-Inférieure. On Feb. 17 he was chosen by the assembly as chief of the executive. His great measures were the immediate negotiation of the preliminary treaty of peace, his crushing of the commune, and the wonderfully successful national loan for paying the German indemnity and the redemption of the territory. On Aug. 31 his term of office was prolonged by the assembly for three years, with the title of president of the republic. He was always a protectionist, and on the rejection of the tariff bill he resigned (Jan. 20, 1872); but he was finally induced to remain, and his subsequent intention to withdraw was arrested (Nov. 29) by the appointment of a committee for regulating his relations with the assembly. In foreign affairs he favored peace and non-intervention. After he had succeeded in substituting Verdun for Belfort as a pledge in German hands, he concluded in March, 1873, a new convention providing for the whole indemnity and for the final withdrawal of the remaining German troops in September, for which he received the thanks of the legislature as one "who deserved well of his country." But on May 24 he was baffled in his attempt to make the republic permanent by legislative enactment, and therefore resigned, and was succeeded by MacMahon. He afterward strongly upheld the republican form of government, which he advocated with great force at Arcachon, Oct. 17, 1875. On Jan. 30, 1876, he was elected to the new senate for Belfort, and on Feb. 20 to the assembly for Paris; and in March he took his seat in the latter body.—His literary fame rests upon his historical works. His other publications include *Histoire de Law* (1826; new ed., 1858; English translation by F. S. Fiske, New York, 1859); *Le monarchie de* 1830 (1831); *De la propriété* (1848); and *L'Homme et la matière* (1875 *et seq.*). Near the close of his life he visited Italy to gather additional materials for a long projected history of art, and was also engaged upon his memoirs. As a speaker his vivacity, parliamentary experience, and perfect mastery of the questions discussed made him exceedingly effective. His house in the place St. Georges, destroyed under the commune, was restored by the government, and continued to be the centre of the most influential society.

**THIERSCH. I. Friedrich Wilhelm**, a German philologist, born at Kirchscheidungen, near Freiburg, June 17, 1784, died in Munich, Feb. 25, 1860. He studied in Leipsic and Göttingen, and in 1809 became professor at the gymnasium in Munich. Being looked upon as a foreigner by the Bavarians, he wrote a vigorous pamphlet entitled *Ueber die angenommenen Unterschiede zwischen Süd- und Norddeutschland* (1810). Soon after its publication an attempt was made to assassinate him. In 1811 he founded a philological institute, which in the following year was incorporated with the university of Munich, and from 1811 to 1829 he edited the *Acta Philologorum Monacensium*. He took a special interest in the Hellenic struggle for independence and in the amelioration of education in Greece, and published in 1833, after a two years' sojourn in that country, *L'état actuel de la Grèce, et des moyens d'arriver à sa restauration*. In his work *Ueber die neuesten Angriffe auf die Universitäten* (1837) he expressed anew his conviction of the importance of classical studies, and in 1838 initiated a bitter literary warfare against Diesterweg, Linde, Schmitthenner, and others, by his *Ueber den gegenwärtigen Zustand des öffentlichen Unterrichts in den westlichen Staaten von Deutschland, in Holland, Frankreich und Belgien*. He wrote a Greek grammar, with special reference to the Homeric dialect, which passed

through several editions, and has been translated into English and other languages. He published also a school edition of this work, an account of his travels in Italy (1826), an edition of Pindar (2 vols., 1850), and other school books and philological treatises. His life has been written by his son Heinrich (2 vols., Leipsic, 1866). **II. Heinrich Wilhelm Josias,** a German theologian, son of the preceding, born in Munich, Nov. 5, 1817. He was professor at Marburg from 1843 to 1864, and subsequently resided at Heidelberg. He is the principal representative of Edward Irving's doctrines in Germany. His works include *Geschichte der Kirche im apostolischen Zeitalter* (2 vols., Frankfort, 1852; English translation, London, 1854), and *Ueber christliches Familienleben* (6th ed., 1872).

**THIONVILLE.** See DIEDENHOFEN.

**THIRD ESTATE.** See STATES GENERAL.

**THIRLWALL, Connop,** an English historian, born at Stepney, Middlesex, Feb. 11, 1797, died July 27, 1875. He was educated at Cambridge, was tutor, Craven scholar, Bell's scholar, and senior chancellor's medallist, received the degree of master in 1821, and became a fellow. He was called to the bar in 1825, but in 1828 entered the church, and became rector of Kirby-under-Dale, Yorkshire. In 1840 he was created bishop of St. Davids, which office he resigned in June, 1874. With J. C. Hare he translated the first two volumes of Niebuhr's "History of Rome" (1828), and he contributed to Lardner's "Cabinet Cyclopædia" a history of Greece (1835 *et seq.*), afterward enlarged (8 vols., 1845–'52). He published a speech delivered in the house of lords in 1869 on the Irish church, and several sermons. His "Literary and Theological Remains" were edited by Canon Perowne (3 vols., London, 1875–'6).

**THIRST,** the sensation by which the want of fluid in the system is made known, dependent on the condition of the stomach, throat, and fauces, and in a state of health a tolerably faithful indication of the requirements of the body. It is generally considered as immediately resulting from an impression on the nerves of the stomach, as it is allayed by the introduction of liquids through a tube, so that the fauces are not touched; in this way speedy relief is obtained, because of the instantaneous absorption of the fluid by the veins of the stomach. This, however, must be taken with some qualification, as the intensity of thirst bears no necessary relation to the amount of liquid in the stomach, but indicates a want of the system which can be supplied through the blood vessels, the rectum, or the skin; in fact, the conditions are very analogous to those mentioned under HUNGER. A supply of fluid, as indicated by thirst, is necessary to make up for the losses by cutaneous and pulmonary exhalation, and by the urinary and other secretions, which are effected chiefly at the expense of the water in the blood. Thirst is greatest in a dry and hot air, when the perspiration and other secretions are excessive; salted or highly spiced food, strong fermented liquors, and irritating substances and poisons applied to the intestinal mucous membrane, excite thirst, no doubt to induce an ingestion of fluid by which they may be diluted. A sudden loss of blood, either by the lancet or from a wound, or a rapid drain on the vascular system, as in Asiatic cholera, diarrhœa, or diabetes, causes thirst in proportion to its amount. Thirst is less when the food is watery, and when liquid can be absorbed by the skin from the surrounding air or water. The thirst of fever does not necessarily indicate a pressing demand for fluids, but depends on the dryness and heat of the throat, mouth, and skin, with diminished transpiration, and is better relieved by small pieces of ice than by copious draughts of water. Animals with naked skins, like batrachians, living in water or moist air, have no need to drink to quench thirst, cutaneous absorption supplying the necessary fluid. The camel, on the other hand, supports thirst for a long time, carrying a supply of fluid in the water stomach. The daily quantity of fluid taken by a man depends upon the temperature, the amount of exercise and perspiration, and the nature of the food. As a general rule, a man in good health, taking a fair amount of bodily exercise, consumes about 2½ lbs. of solid food and rather less than 3 lbs. of liquid food in a day. But as most articles of solid food, such as meat, bread, and vegetables, themselves contain a notable proportion of water, they contribute so far to satisfy the daily demand for liquids. The body requires to be supplied, either in the solid or liquid form, with about 4½ lbs. of water daily; and if this quantity from any cause be deficient, the sensation of thirst indicates the requirements of the system. Every loss of water from the body, as above mentioned, increases this demand. Consequently, when from any accidental circumstance, as in cases of shipwreck, a sufficient supply of water for drink cannot be obtained, every care should be taken to prevent the loss of fluids from the system. The avoidance of perspiration, the protection of the skin from evaporation, and frequent bathing in salt water when practicable, are all efficient in diminishing the danger, and in protracting as long as possible the period of endurance.

**THIRTY YEARS' WAR,** a religious and political conflict which involved the German empire, and with it the principal states of Europe, from 1618 to 1648. The causes which led to this struggle reach back to the early part of the 16th century, when the reformation divided Germany into two hostile religious parties. Protestantism, nearly crushed in the war of the Smalcald league, rose triumphant under Maurice of Saxony, and with the peace of Augsburg (1555) Charles V. beheld the chief aim of his policy for ever frustrated. By the terms of this peace, which extended to those Protestants only who had embraced the confession of Augsburg, the right was secured to each

state of prescribing the form of worship within its limits, and to all subjects, Lutheran or Catholic, the privilege of emigrating from the states where their creed was prohibited. The Protestants were to retain the ecclesiastical possessions which they had appropriated previous to the peace of Passau in 1552. But though the basis of a definite settlement was established, two important points remained on which no agreement could be reached. The Catholic party, to guard against the danger that would accrue to the church in the future appropriation of her prelacies by the Protestants, introduced an article, known as the ecclesiastical reservation, by which all prelates who should henceforth abjure Catholicism were to forfeit their benefices. This article was inserted against the protest of the Lutheran members of the diet. The other point related to Protestant subjects in the ecclesiastical states, for whom the Protestant members sought to secure the right of worship in such territories. The Catholics refused to admit such an article, and they could only obtain instead a personal declaration to the same effect from the emperor's brother Ferdinand, who presided at the diet of Augsburg. The exclusion of the Calvinists proved another source of contention. Under the rule of Ferdinand I. (1556–'64) and his son, the mild Maximilian II. (1564–'76), a general tranquillity was maintained, while the balance was fast turning toward the side of the Protestants, who in the Austrian territories began to tyrannize over the Catholics. The bigoted Rudolph II. (1576–1612), swayed by the Jesuits and the court of Spain, resolved to repress Protestantism, and in his immediate dominions proceeded to restrict, and finally even to abolish the Protestant worship. Religious disputes again distracted Germany. The enmity between Lutherans and Calvinists equalled their mutual hate for the Catholics. The aulic council, whose decisions were inspired by the imperial court, usurped an unlawful jurisdiction in the empire. In Aix-la-Chapelle the Protestants established their worship in spite of the Catholics (1580), and at first beat back the troops sent to execute the imperial ban. About the same time an opportunity was presented of enforcing the ecclesiastical reservation. Gebhard, archbishop of Cologne, abjured his faith to marry a Calvinist lady, but determined not to renounce his see. He was accordingly placed under the ban of the empire, and a war ensued, which ended in his defeat and expulsion in 1584. A violent contest followed for the see of Strasburg. In 1607 the Protestant imperial city of Donauwörth, whose inhabitants an abbot had provoked to acts of violence by processions, prohibited within the town, was deprived of its liberties, in open violation of the peace of religion. Alarmed for their safety, the Protestant princes, in May, 1608, formed at Auhausen in Franconia an offensive and defensive league styled the "Evangelical Union." It soon comprised the Palatinate, Neuburg, Baden, Würtemberg, Brandenburg, Strasburg, Nuremberg, and other states of the empire. Frederick IV., elector palatine, a Calvinist, was placed at its head, though its most active member was Christian of Anhalt. The Lutheran elector of Saxony, however, declined to join the union. On their side the Catholic states, independently of Austria, established the league (July, 1609), with Maximilian, duke of Bavaria, at their head. In the mean while the Protestants of Hungary and Austria had risen against Rudolph and recovered their rights (see RUDOLPH II., and MATTHIAS); and thus encouraged, their brethren in Bohemia, in July, 1609, wrung the *Majestätsbrief* from the emperor. Amid these disorders the heirless duke of Jülich died (March, 1609), leaving a host of claimants to his dominions, which were at once jointly seized by Brandenburg and Neuburg. Rudolph ordered a levy of troops to enforce their sequestration. The Protestant princes flew to arms, and invoked the aid of France, the Netherlands, and other powers. Henry IV. of France now hoped to execute his design of humbling the house of Hapsburg, and was preparing to invade Germany when the dagger of Ravaillac terminated his career (May 14, 1610). Hostilities ceased, but under the emperor Matthias, who succeeded in 1612, the unsettled claims of Jülich again led to war, and Dutch and Spaniards, called in by Brandenburg and Neuburg respectively, occupied the disputed lands. Matthias, being without heirs, was induced to put forward as his successor his cousin Ferdinand of the Styrian line, whose bigotry and rigor alarmed the Protestants. Ferdinand was nevertheless crowned in Bohemia in 1617 and in Hungary in 1618. But already in Bohemia an event had occurred which precipitated the thirty years' war. The Protestant inhabitants of Klostergraben and Braunau had erected new churches against the prohibition of the archbishop of Prague and the abbot of Braunau, lords of the two places, who enforced their authority by seizing the buildings. Protestants and Catholics appealed to a somewhat obscurely worded clause in the *Majestätsbrief*, which the former contended gave the right of building new churches to the Protestants of the towns in general, while the latter maintained that it extended only to the states and royal towns. The court supported the Catholics, and refused all redress. The storm now burst. On May 23, 1618, an assemblage of Protestants, led by Count Thurn, entered the palace at Prague, and seizing Slavata and Martinitz, the most odious members of the council of regency appointed by the crown, hurled them together with their secretary from a lofty window. They escaped as if by a miracle. Thurn and his associates organized a general rising, and evoked the assistance of the union and of Bethlen Gábor of Transylvania. In a short time nearly all Bohemia was in their hands. They were joined by the Sile-
